1752. INVENTION AND DISCOVERY—*The Discoverer Rarely an Inventor.*—By a discovery in science is understood the development of a knowledge of the existence of some principle in Nature not before known or but partially understood, while the term invention indicates the application of this knowledge, either simply or in combination with other knowledge, to some useful purpose in the arts. For example, Franklin discovered the principle of electrical induction, or the action at a distance of a charged body on a conductor, and on this founded his invention of the lightning-rod. It sometimes happens that the peculiar characteristics of mind and training necessary to the successful prosecution of these two branches of labor are found combined in the same individual. Of a happy combination of this kind James Watt affords a striking example, the like of which will become more common in proportion as the means of intellectual improvement afforded to workmen are extended. Generally, however, the two faculties exist in the greatest degree of development in separate individuals. The successful investigation of a new principle in science generally requires much previous study and preparation and a logical training, which few men, however vigorous may be their native intellect, can dispense with, and to acquire which the opportunities of the workmen are inadequate. On the other hand, the successful introduction to common use of an invention requires a contest with the world from which the sensitive student of abstract science shrinks with repugnance. I consider these remarks of some importance, because in this country, where there is so great a demand for immediate practical results, the value of labor in the line of abstract science is not properly appreciated or encouraged.—HENRY *Improvement of the Mechanical Arts (Scientific Writings*, vol. i, p. 319). (Sm. Inst., 1886.)

1753. INVENTION A NECESSITY FOR PRIMITIVE WOMAN—To feed the flock under her immediate care woman had to become an inventor, and it is in this activity of her mind that she is specially interesting here. The hen scratches for her chicks all day long, because Nature has fastened her hoes and rakes and cutting apparatus upon her body. But here stands a creature on the edge of time who had to create the implements of such industry. It is true that all the ages and all experiences and examples of the zoological world were around her. So had they been around other creatures. But the power to associate new ideas constantly and independently was to be for the first time her peculiar endowment as a bringer of food.—MASON *Woman's Share in Primitive Culture*, ch. 2, p. 14. (A., 1894.)

1754. INVENTION DRIVING TO INVENTION—*Scattered Workers Crowded Together—Time and Cost of Collection Fatal —The Factory System Becomes a Necessity.* —Towards the middle of the eighteenth century the greatest difficulty was experienced by weavers and spinners in England in maintaining their position in the markets of the world. It is curious how each new mechanical invention gave rise to the necessities out of which the next arose. The invention of the fly-shuttle in weaving, so early as 1733, seems to have given the first impulse to all that followed. By means of this invention the power of weaving overtook the power of spinning. An adequate supply of yarn could not be procured under the ancient methods of that most ancient industry. New conditions gave rise to new motives, and new motives called into play the latent energies of mind. The time and the cost of collecting the products of so many scattered laborers enhanced unduly the cost of manufacture, and even when the remuneration was reduced to the lowest point compatible with existence that cost was still too high. Something was imperatively required to economize the work of human hands—some more elaborate contrivance to make that work go further than before. And so Hargreaves's invention arose, not before the time. And when his spinning-jenny had been invented, a still more elaborate and powerful combination of mechanical adjustments was soon perfected in the hands of Arkwright. When the spinning-frame was invented, and when Crompton's farther invention of the mule-jenny speedily followed, the new order of things had been fairly inaugurated. The great change had come, and the survivance of the ancient domestic industries of so many centuries was no longer possible.—ARGYLL *Reign of Law*, ch. 7, p. 206. (Burt.)

1755. INVENTION GIVES INCREASING POWER—*Great Results from Small Beginning—Magnetic Induction.*—The story of the discovery of magnetic induction by Faraday and Henry is most instructive, for it shows how an apparently slight and unimportant manifestation of energy can be exalted by proper means into a tremendous one. Faraday remarked, after detailing his experiments on magnetic induction: "The various experiments of this section prove, I think, most completely the production of electricity from ordinary magnetism. That

its intensity should be very feeble and quantity small cannot be considered wonderful when it is remembered that, like thermo-electricity, it is evolved entirely within the substance of metals retaining all their conducting power." The steam-engine has exalted this apparently feeble effect discovered by Faraday into a power which is only limited by that of the steam-engine or the water-power which we employ.—TROWBRIDGE *What is Electricity?* ch. 1, p. 9. (A., 1899.)

1756. INVENTION INDIGENOUS IN MAN—Invention is indigenous in the nature of man. The first being on this earth worthy of that name was an inventor. The only moment in the life of an individual or a people in which the distinction of true humanity may be worthily bestowed on them is that in which something new is added to the stock of knowledge or experience. When men or nations originate, they live and grow; when they cease to do that, they decay and die. This has been true from the beginning.—MASON *Origins of Invention*, ch. 12, p. 410. (S., 1899.)

1757. INVENTION OF THE SAND-BLAST—*Man Taught by Processes of Nature.*—The sphinx of Egypt is nearly covered up by the sand of the desert. The neck of the sphinx is partly cut across, not, as I am assured by Mr. Huxley, by ordinary weathering, but by the eroding action of the fine sand blown against it. In these cases Nature furnishes us with hints which may be taken advantage of in art; and this action of sand has been recently turned to extraordinary account in the United States. When in Boston [1872] I was taken by my courteous and helpful friend, Mr. Josiah Quincey, to see the action of the sand-blast. A kind of hopper containing fine silicious sand was connected with a reservoir of compressed air, the pressure being variable at pleasure. The hopper ended in a long slit, from which the sand was blown. A plate of glass was placed beneath this slit and caused to pass slowly under it; it came out perfectly depolished, with a bright opalescent glimmer, such as could only be produced by the most careful grinding. Every little particle of sand urged against the glass, having all its energy concentrated on the point of impact, formed there a little pit, the depolished surface consisting of innumerable hollows of this description.—TYNDALL *Fragments of Science*, vol. i, ch. 7, p. 193. (A., 1897.)

1758. INVENTION UNSUCCESSFUL—*Destructibility of Lava—Artificial Stone Lacks Endurance.*—Some years ago a very ingenious invention was submitted to trial in the works of the Messrs. Chance, of Birmingham. It had been suggested that if certain lavas of easy fusibility were melted and poured into molds we might thus obtain elaborately ornamented stonework, composed of the hardest material, without the labor of the mason. The molten rock when quickly cooled was found to assume the form of a black glass, but when very slowly cooled passed into a stony material. Unfortunately, it was found that this material did not withstand the weather like ordinary building stones, and in consequence the manufacture had to be abandoned.—JUDD *Volcanoes*, ch. 3, p. 5. (A., 1899.)

1759. INVENTIONS OF PRIMITIVE MAN—*The Roller and the Pulley among American Aborigines.*—The roller I have found certainly in two areas. The Eskimos, in landing a heavily laden skin-boat, according to Elliott, lay down on the beach, in a row, inflated sealskins, used as floats with their harpoons. Upon these the craft is beached without the vexation of unloading her. A moment's reflection will show that in this apparatus the pneumatic tire is foreshadowed. The other example of the roller is the use made of it on the North Pacific coast in moving the great logs to be used in constructing the communal houses. The pulley in its simplest form is described as an invention of tepee-dwelling Indians of the plains. When the women had set up the three chief poles of the tent, the skin cover was hauled up by a line fastened to the top margin, passed over the fork of the poles above, and hauled by women at the other end. When the time came to strike tent, the line was loosed and the poles drawn together at their bases. Elliott, however, figures a group of Eskimos landing a huge walrus by means of a compound pulley. A long, stout walrus line passes around greasy pegs driven between the rocks and through slits cut in the animal's hide.—MASON *Aboriginal American Mechanics* (*Memoirs of the International Congress of Anthropology*, p. 76). (Sch. P. C.)

1760. INVESTIGATION, ORIGINAL—*The Mainspring of Technical Education.*—At the present time there is a cry in England for technical education, and it is a cry in which the most commonplace intellect can join, its necessity is so obvious. But there is no cry for original investigation. Still without this, as surely as the stream dwindles when the spring dies, so surely will "technical education" lose all force of growth, all power of reproduction. Our great investigators have given us sufficient work for a time; but if their spirit die out we shall find ourselves eventually in the condition of those Chinese mentioned by De Tocqueville, who, having forgotten the scientific origin of what they did, were at length compelled to copy without variation the inventions of an ancestry wiser than themselves who had drawn their inspiration direct from Nature.—TYNDALL *Lectures on Light*, p. 218. (A., 1898.)

1761. INVESTIGATION, UNTIRING SPIRIT OF, IN MONKEY—*Patient Industry Evinced.*—In conclusion, I should say that

much the most striking feature in the psychology of this animal [a brown capuchin monkey], and the one which is least like anything met with in other animals, was the tireless spirit of investigation. The hours and hours of patient industry which this poor monkey has spent in ascertaining all that his monkey intelligence could of the sundry unfamiliar objects that fell into his hands might well read a lesson in carefulness to many a hasty observer. And the keen satisfaction which he displayed when he had succeeded in making any little discovery, such as that of the mechanical principle of the screw, repeating the results of his newly earned knowledge over and over again, till one could not but marvel at the intent abstraction of the "dumb brute"—this was so different from anything to be met with in any other animal that I confess I should not have believed what I saw unless I had repeatedly seen it with my own eyes. As my sister once observed while we were watching him conducting some of his researches, in oblivion to his food and all his other surroundings, "When a monkey behaves like this it is no wonder that man is a scientific animal!"—ROMANES *Animal Intelligence*, ch. 17, p. 497. (A., 1899.)

1762. INVESTIGATION VS. DOGMA—*The Scientific Spirit.*—The history of science teaches us the difficulties that have opposed the progress of this active spirit of inquiry. Inaccurate and imperfect observations have led, by false inductions, to the great number of physical views that have been perpetuated as popular prejudices among all classes of society. Thus by the side of a solid and scientific knowledge of natural phenomena there has been preserved a system of the pretended results of observation, which is so much the more difficult to shake, as it denies the validity of the facts by which it may be refuted. This empiricism, the melancholy heritage transmitted to us from former times, invariably contends for the truth of its axioms with the arrogance of a narrow-minded spirit. Physical philosophy, on the other hand, when based upon science, doubts because it seeks to investigate, distinguishes between that which is certain and that which is merely probable, and strives incessantly to perfect theory by extending the circle of observation.—HUMBOLDT *Cosmos*, vol. i, int., p. 38. (H., 1897.)

1763. INVESTIGATORS OFTEN BAD LECTURERS—*Advanced Thinker Sees Things in Masses—Anecdote of Laplace.*—An advanced thinker sees the relations of his topics in such masses and so instantaneously that when he comes to explain to younger minds it is often hard to say which grows the more perplexed, he or the pupil. In every university there are admirable investigators who are notoriously bad lecturers. The reason is that they never spontaneously see the subject in the minute articulate way in which the student needs to have it offered to his slow reception. They grope for the links, but the links do not come. Bowditch, who translated and annotated Laplace's "Mécanique Céleste," said that whenever his author prefaced a proposition by the words "it is evident," he knew that many hours of hard study lay before him.—JAMES *Psychology*, vol. ii, ch. 22, p. 369. (H. H. & Co., 1899.)

1764. INVIGORATION OF NEGATIVE CHARACTER—*Overcoming, Not Removal of Difficulties—Self-reliance To Be Fostered.*—With a character of [the negative] type, the object of the judicious educator will be to invigorate the whole nature, corporeal as well as physical; to find out what worthy objects of pursuit have the most attraction for his pupil, and to aid and encourage his steady pursuit of them, not by removing difficulties from his path, but by helping him to surmount them, and in this manner to foster habits of self-reliance, which, when once formed, whether in regard to manly exercises or to the work of the intellect, may be looked to as available for the moral direction of the conduct.—CARPENTER *Mental Physiology*, bk. i, ch. 9, p. 428. (A., 1900.)

1765. INVISIBLE, THE, MADE VISIBLE—*Ultraviolet Waves Revealed by Fluorescence.*—As a general rule, bodies either transmit light or absorb it; but there is a third case in which the light falling upon the body is neither transmitted nor absorbed, but converted into light of another kind. Professor Stokes, the occupant of the chair of Newton in the University of Cambridge, has demonstrated this change of one kind of light into another, and has pushed his experiments so far as to render the invisible rays visible. A large number of substances examined by Stokes, when excited by the invisible ultraviolet waves, have been proved to emit light. You know the rate of vibration corresponding to the extreme violet of the spectrum; you are aware that to produce the impression of this color, the retina is struck 789 millions of millions of times in a second. At this point, the retina ceases to be useful as an organ of vision, for tho struck by waves of more rapid recurrence, they are incompetent to awaken the sensation of light. But when such nonvisual waves are caused to impinge upon the molecules of certain substances—on those of sulfate of quinin, for example—they compel those molecules, or their constituent atoms, to vibrate; and the peculiarity is, that the vibrations thus set up are of slower period than those of the exciting waves. By this lowering of the rate of vibration through the intermediation of the sulfate of quinin, the invisible rays are brought within the range of vision. . . . Casting by means of a prism a spectrum . . . upon a sheet of paper which has been wetted with a saturated solution of the sulfate of

quinin, and afterwards dried, an obvious extension of the spectrum is revealed. We have, in the first instance, a portion of the violet rendered whiter and more brilliant; but, besides this, we have the gleaming of the color where, in the case of unprepared paper, nothing is seen. Other substances produce a similar effect. A substance, for example, recently discovered by President Morton, and named by him thallene, produces a very striking elongation of the spectrum, the new light generated being of peculiar brilliancy. . . . [Stokes] called this rendering visible of the ultraviolet rays fluorescence.—TYNDALL *Lectures on Light*, lect. 4, p. 163. (A., 1898.)

1766. IRON AMONG THE HEBREWS —*Discovery of Dim Antiquity.*—It has been suggested that such iron as has been found in Egypt, and referred to Pharaonic times, may have been made and used by the Hebrews during their servitude, and that when they left the country they carried their knowledge with them. That they were familiar with the metal at the period of Moses, and hence at about 1500 years B. C., and possibly had known of it then for a long time, is shown by the mention of Tubal Cain, "an instructor of every artificer in brass and iron," as a personage of great antiquity, at the very beginning of the Pentateuch. Their continuing knowledge of it, over many centuries, is further shown by the Biblical references to the bed of iron of Og, the iron chariots of Javin, the miraculous floating ax-head of Elisha, the question "shall iron break the northern iron and the steel" in the Jeremiad, and many other instances, easily found.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 1, p. 28. (J. W., 1898.)

1767. IRRELIGION MAY RESULT FROM DEGENERACY—It must be remembered that even if it had been true that some savages do exist with no conception whatever of living beings higher than themselves, it would be no proof whatever that such was the primeval condition of man. The . . . most degraded savagery of the present day is or may be the result of evolution working upon highly unfavorable conditions. . . . Degradation being a process which has certainly operated, and is now operating upon some races, and to some extent, it must always remain a question how far this process may go in paralyzing the activity of our higher powers, or in setting them, as it were, to sleep.—ARGYLL *Unity of Nature*, ch. 11, p. 281. (Burt.)

1768. IRRIGATION, SYSTEM OF, AMONG NORTH-AMERICAN INDIANS—No aborigines, unaided by domestic animals, have displayed so much patience and ingenuity in the storage and conducting of water as the Indians of the arid region of the United States. Throughout the public region, says Mr. Hodge, works of irrigation abound in the valleys and on the mountain slopes, especially along the drainage of the Gila and the Salado, in Southern Arizona, where the inhabitants are engaged in agriculture to a vast extent by this means. The arable tract of the Salado comprises 450,000 acres, and the ancient inhabitants controlled the watering of at least 250,000 acres. The outlines of one hundred and fifty miles of ancient main irrigating ditches may be readily traced, some of which meander southward a distance of fourteen miles. In one place the main canal was found to be a ditch within a ditch, the bed being seven feet deep. The lower section was only four feet wide, but the sides broadened in their ascent to a "bench" three feet wide on each side of the canal. Remains of balsas were recovered, showing that the transportation of material was also carried on. Remains of flood-gates were found by Mr. Cushing, and great reservoirs for storage of water, one example being 200 feet long and 15 feet in depth.—MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology*, p. 82). (Sch. P. C.)

1769. IRRITATION OF SKIN BY ALPINE SUNSHINE—*Power of Chemical Rays.*—There would seem to be some specific quality in the sun's rays which produces the irritation of the skin experienced in the Alps. The solar heat may be compared, in point of *quantity*, with that radiated from a furnace; and the heat encountered by the mountaineer on Alpine snows is certainly less intense than that endured by workmen in many of our technical operations. But the terrestrial heat appears to lack the *quality* which gives the solar rays their power. The sun is incomparably richer in what are called chemical rays than are our fires, and to such rays the irritation may be due.—TYNDALL *Hours of Exercise in the Alps*, ch. 15, p. 169. (A., 1898.)

1770. ISLAND CREATED IN ONE GENERATION—There can be little doubt, from the account given by Captain Beechey, that Matilda Atoll in the Low Archipelago has been converted in the space of thirty-four years from being, as described by the crew of a wrecked whaling-vessel, a "reef of rocks," into a lagoon-island fourteen miles in length, with "one of its sides covered nearly the whole way with high trees." The islets, also, on Keeling Atoll, it has been shown, have increased in length, and since the construction of an old chart several of them have become united into one long islet.—DARWIN *Coral Reefs*, ch. 4, p. 101. (A., 1900.)

1771. ISLAND RISES AMONG AZORES—*Wide-spread Earthquakes—Distant Echo of Eruption.*—The sudden appearance, on the 30th of January, 1811, of the island of Sabrina, in the group of the Azores, was the precursor of the dreadful earthquakes which, further westward, shook, from May, 1811 to June, 1813, almost uninterruptedly,

first the Antilles, then the plains of the Ohio and Mississippi, and lastly the opposite coasts of Venezuela or Caracas. Thirty days after the total destruction of the beautiful capital of the province there was an eruption of the long inactive volcano of St. Vincent, in the neighboring islands of the Antilles. A remarkable phenomenon accompanied this eruption; at the moment of this explosion, which occurred on the 30th of April, 1811, a terrible subterranean noise was heard in South America, over a district of more than 35,000 square miles. The inhabitants of the banks of the Apure, at the confluence of the Rio Nula, and those living on the remote seacoast of Venezuela, agreed in comparing this sound to the noise of heavy artillery. The distance from the confluence of the Rio Nula with the Apure (by which I entered the Orinoco) to the volcano of St. Vincent, measured in a straight line, is no less than 628 miles. This noise was certainly not propagated through the air, and must have arisen from some deep-seated subterranean cause; its intensity was, moreover, hardly greater on the shores of the Caribbean Sea, near the seat of the raging volcano, than in the interior of the country in the basin of the Apure and the Orinoco.—HUMBOLDT *Views of Nature*, p. 361. (Bell, 1896.)

1772. ISLANDS OF CORAL—*Growing in Spite of Beating Surge—Advance against Resistance.*—Of thirty-two of these coral islands visited by Beechey in his voyage to the Pacific, twenty-nine had lagoons in their centers. The largest was 30 miles in diameter and the smallest less than a mile. All were increasing their dimensions by the active operations of the lithophytes, which appeared to be gradually extending and bringing the immersed parts of their structure to the surface. The scene presented by these annular reefs is equally striking for its singularity and beauty. A strip of land a few hundred yards wide is covered by lofty coconut-trees, above which is the blue vault of heaven. This band of verdure is bounded by a beach of glittering white sand, the outer margin of which is encircled with a ring of snow-white breakers, beyond which are the dark, heaving waters of the ocean. The inner beach encloses the still clear water of the lagoon, resting in its greater part on white sand, and, when illuminated by a vertical sun, of a most vivid green. Certain species of zoophytes abound most in the lagoon, others on the exterior margin where there is a great surf. "The ocean," says Mr. Darwin, "throwing its breakers on these outer shores, appears an invincible enemy, yet we see it resisted and even conquered by means which at first seem most weak and inefficient. No periods of repose are granted, and the long swell caused by the steady action of the trade-wind never ceases. The breakers exceed in violence those of our temperate regions, and it is impossible to behold them without feeling a conviction that rocks of granite or quartz would ultimately yield and be demolished by such irresistible forces. Yet these low, insignificant coral islets stand and are victorious, for here another power, as antagonist to the former, takes part in the contest. The organic forces separate the atoms of carbonate of lime one by one from the foaming breakers, and unite them into a symmetrical structure; myriads of architects are at work night and day, month after month, and we see their soft and gelatinous bodies through the agency of the vital laws conquering the great mechanical power of the waves of an ocean, which neither the art of man nor the inanimate works of Nature could successfully resist."—LYELL *Principles of Geology*, bk. iii, ch. 50, p. 780. (A., 1854.)

1773. ISLANDS OF FLOATING SEAWEED — *The Sargasso Fauna — Floating Homes of Marine Animals.*—The pelagic zone may be divided into several geographical regions and subregions, which it would be beyond the scope of this book to enumerate here, but there is one that calls for a few brief remarks. In many parts of the ocean there may be found vast areas of floating seaweed [sargasso] which carry with them a population of *Crustacea* and other animals peculiarly their own. This Sargasso fauna presents so many characteristics and so many features different from that of the ordinary pelagic fauna that the tracts of sea bearing this weed must be considered to rank as a special region of the pelagic zone, which may be called the "Sargasso region."—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 48. (A., 1894.)

1774. ISOLATION OF OUR SUN—*Distance from Alpha Centauri—Seventy-five Million Years by Express Train.*—Our sun, a star in the immensity, is isolated in infinitude, and the nearest sun reigns at 10 trillions of leagues (25 billions of miles) from our terrestrial abode. Notwithstanding its unimaginable velocity of 186,400 miles a second, light moves, flies, during four years and 128 days to come from this sun to us. Sound would take more than 3 millions of years to cross the same abyss. At the constant velocity of 60 kilometers (37 miles) an hour an express train starting from the sun Alpha Centauri would not arrive here till after an uninterrupted course of nearly 75 millions of years.—FLAMMARION *Popular Astronomy*, bk. v, ch. 5, p. 599. (A.)

1775. ——— ——— *Independence of Each Sun in Its Own Domain.*—Thus our sun and the neighboring suns are isolated. Each is an independent king in its own province, and if they feel each other across the infinite, and are subject to the influence of their reciprocal attraction, it is but a suzerainty of little effect. The motions

which animate them are of an order superior to their respective attractions.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 5, p. 600. (A.)

1776. ISOLATION OF SEQUOIAS—*Origin of the Redwood Mysterious.*—One notable thing about the sequioa-trees is their isolation. Most of the trees associated with them are of peculiar species, and some of them are nearly as local. Yet every pine, fir, and cypress of California is in some sort familiar, because it has near relatives in other parts of the world. But the redwoods have none. The redwood—including in that name the two species of "big trees"—belongs to the general cypress family, but is *sui generis*. Thus isolated systematically, and extremely isolated geographically, and so wonderful in size and port, they more than other trees suggest questions.—GRAY *Darwiniana*, art. 5, p. 208. (A., 1899.)

1777. ISOLATION OF THE SOLAR SYSTEM—*Stellar Distances.*—The solar system seems to us very vast, the abyss which separates our world from Mars, Jupiter, Saturn, and Neptune appears to us immense; relatively to the fixed stars, however, our whole system represents but an isolated family immediately surrounding us; a sphere as vast as the whole solar system would be reduced to the size of a simple point if it were transported to the distance of the nearest star. The space which extends between the solar system and the stars, and which separates the stars from each other, seems to be entirely void of visible matter, with the exception of nebulous fragments, cometary or meteoric, which circulate here and there in the immense voids. Nine thousand two hundred and fifty systems like ours (bounded by Neptune) would be contained in the space which isolates us from the nearest star!

If a terrible explosion occurred in this star, and if the sound could traverse the void which separates it from us, this sound would take more than three millions of years to reach us.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 1, p. 553. (A.)

1778. JOURNEY THROUGH TRACKLESS SPACE—*Migration of Oriole and Bobolink.*—The oriole, who builds his swinging nest in your elm-tree, will winter in Central America; the bobolink, who seems so carefree in your meadows, must journey to his winter quarters in southern Brazil. But, unless accident befalls, both birds will return to you the following spring. We are so accustomed to these phenomena that we accept them as part of the changing seasons without realizing how wonderful they are. But look for a moment at a map and try to form a mental picture of the bobolink's route. Over valleys, mountains, marshes, plains, and forests, over straits and seas hundreds of miles in width, he pursues a course through trackless space with a regularity and certainty which bring him to the same place at nearly the same time year after year. How much of his knowledge of the route he has inherited, and how much learned during his own lifetime, is a question.—CHAPMAN *Bird-Life*, ch. 4, p. 54. (A., 1900.)

1779. JOY EXALTS AS GRIEF DEPRESSES—*Muscles, Arteries, and Nutrition Affected by Mental States.*—The familiar observations—first, that a lively hope or joy exerts an enlivening effect upon the bodily life, quiet and equable when moderate, but, when stronger, evinced in the brilliancy of the eye, in the quickened pulse and respiration, in an inclination to laugh and sing; and, secondly, that grief or other depressing passion has an opposite effect, relaxing the arteries, enfeebling the heart, making the eye dull, impeding digestion, and producing an inclination to sigh and weep—these familiar observations of opposite effects indicate the large part which mental states may play, not in the causation of all sorts of diseases alone, but in aiding recovery from them. A sudden and great mental shock may, like a great physical shock, and perhaps in the same way, paralyze for a time all the bodily and mental functions, or cause instant death. It may, again, produce epilepsy, apoplexy, or insanity, while a prolonged state of depression and anxiety is sometimes an important agent in the causation of chronic disease, such as diabetes and heart-disease. Can it be doubted, too, that the strong belief that a bodily disorder will be cured by some appliance, itself innocent of good or harm, may so affect beneficially the nutrition of the part as actually to effect a cure? To me it seems not unreasonable to suppose that the mind may stamp its tone, if not its very features, on the individual elements of the body, inspiring them with hope and energy, or infecting them with despair and feebleness.—MAUDSLEY *Body and Mind*, lect. 1, p. 38. (A., 1898.)

1780. JOY OF DISCOVERY—There is a certain form of emotion called intellectual pleasure which may be excited by poetry, literature, Nature, or art. But I doubt whether among the pleasures of the intellect there is any more pure and concentrated than that experienced by the scientific man when a difficulty which has challenged the human mind for ages melts before his eyes and recrystallizes as an illustration of natural law.—TYNDALL *New Fragments*, p. 202. (A., 1897.)

1781. JOY OR SORROW EXAGGERATED IN MEMORY—*Minds Differ in Choice of Images Retained.*—Besides the impossibility of getting at the average and prevailing mental tone of a distant section of life, there is a special difficulty in determining the degree of happiness of the past, arising from the fact that our memory for pleasures and for pains may not be equally good. Most people, perhaps, can recall the enjoyments of the past much more vividly than

the sufferings. On the other hand there seem to be some who find the retention of the latter the easier of the two. This fact should not be forgotten in reading the narrative of early hardships which some recent autobiographies have given us.—SULLY *Illusions*, ch. 10, p. 264. (A., 1897.)

1782. JUDGMENT OF INTENSITY OF SENSATION—*Quantitative, but with No Degrees—Merely "More" or "Less."*—If we compare with each other two different sensations of the same modality we are undoubtedly able to pass judgment regarding their intensities. Our judgment runs either: the sensations are of equal intensity, or, they are not of equal intensity. The midday sun we assert to be brighter than the moon, the roar of a cannon louder than the crack of a pistol, a hundredweight heavier than a pound. These comparative judgments are taken directly from sensation. We really state in them merely this: that the sensations which the sunshine, the cannon, and the hundredweight arouse in us are more intensive than the sensations which we have from the moon, a pistol-shot, or a poundweight. There is therefore possible a quantitative comparison of sensations. We can say of two sensations that they are of equal intensity, or that this one is of a greater or less intensity than the other. There our measurement of sensation ordinarily rests. We are not able to say how much stronger or how much weaker one is than another. We cannot estimate in the least whether the sun is a hundred or a thousand times brighter than the moon, the cannon a hundred or a thousand times louder than the pistol. Our ordinary measurement of sensation tells us only of "equality," of a "more" or of a "less," never of a "so much more" or "less."—WUNDT *Psychology*, lect. 2, p. 17. (Son. & Co., 1896.)

1783. KAIAK VERSUS OCEAN STEAMER—What is more beautiful than an ocean steamer, with skin of steel drawn over ribs of steel and closed above against the intrusion of the waves? Have you never seen the picture of the Eskimo, still in the Stone Age, who, over a framework of driftwood or whale's rib, stretches a covering of sealskin and learned therein to defy the waves hundreds of years ago?—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891, Proceedings of the Congress*, p. 407).

1784. KINDRED WITH THE DIVINE—*Kinship with Beasts Cannot Satisfy the Soul—Exaltation by Influence of Higher Intelligence—The Dog and His Master.*—They that deny a God destroy a man's nobility; for certainly man is of kin to the beasts by his body; and if he be not of kin to God by his spirit, he is a base and ignoble creature. It destroys likewise magnanimity, and the raising of human nature; for take an example of a dog, and mark what a generosity and courage he will put on when he finds himself maintained by a man, who to him is instead of a god, or "*melior natura*"; which courage is manifestly such as that creature, without that confidence of a better nature than his own, could never attain. So man, when he resteth and assureth himself upon divine protection and favor, gathereth a force and faith, which human nature in itself could not obtain; therefore, as atheism is in all respects hateful, so in this, that it depriveth human nature of the means to exalt itself above human frailty.—BACON *Essays*, essay 16, *Of Atheism*, p. 61. (W. L. A.)

1785. KINGDOM, DISTINCT, REQUIRED FOR PSYCHOLOGICAL MAN—*Gulf between Man and Ape.*—Mr. Mivart has truly said that, with regard to their total value in Nature, the difference between man and ape transcends the difference between ape and blade of grass. I should be disposed to go further and say that while for zoological man you can hardly erect a distinct family from that of the chimpanzee and orang, on the other hand, for psychological man you must erect a distinct kingdom; nay, you must even dichotomize the universe, putting man on one side and all things else on the other.—FISKE *Through Nature to God*, pt. ii, ch. 5, p. 82. (H. M. & Co., 1900.)

1786. KITCHEN, THE, A CHEMICAL LABORATORY — *Crude Materials Transformed for Food.*—The kitchen is a chemical laboratory in which are conducted a number of chemical processes by which our food is converted from its crude state to a condition more suitable for digestion and nutrition, and made more agreeable to the palate.—WILLIAMS *Chemistry of Cookery*, ch. 1, p. 4. (A., 1900.)

1787. KLEPTOMANIA A REAL INSANITY—*Hoarding of Useless Treasures.*—Kleptomania, as it is called, is an uncontrollable impulse to appropriate, occurring in persons whose "associations of ideas" would naturally all be of a counteracting sort. Kleptomaniacs often promptly restore or permit to be restored what they have taken; so the impulse need not be to keep, but only to take. But elsewhere hoarding complicates the result. A gentleman with whose case I am acquainted was discovered, after his death, to have a hoard in his barn of all sorts of articles, mainly of a trumpery sort, but including pieces of silver which he had stolen from his own dining-room, and utensils which he had stolen from his own kitchen, and for which he had afterward bought substitutes with his own money.—JAMES *Psychology*, vol. ii, ch. 24, p. 425. (H. H. & Co., 1899.)

1788. KNIVES OF SHARKS' TEETH—*Gain Attending the Iron Blade.*—It will be found in the study of industrial knives that in the long run they become the

carver's and engraver's tools, the drawing-knife, the spoke-shave, the plane, and the planing-mill. In some styles of the last-named, however, the operative part of the machine is, more properly speaking, a machine adz than a knife. Carving in wood and other substances by the American aborigines differentiated the adz from the knife. It is probable that before the introduction of iron into America the adz was used more than the knife in dressing down wood; but when the iron blade came into vogue it was possible for the savage workman to carve out hollow dishes and boxes and other objects with his knife by simple pressure. Notable exceptions to this are those regions where soft wood came into alliance with sharks' teeth and the incisors of rodents. This is shown in all the curved knives of the collections in the United States National Museum from the two hemispheres, especially those from wooded areas.—MASON *The Man's Knife among the North American Indians (Report of U. S. National Museum for 1897,* p. 727).

1789. KNOWLEDGE ACQUIRED BY LEARNING TO DOUBT—*Boiling of Food for the Table—Cooking of Food Man's Immemorial Custom.*—"The process by which food is most commonly prepared for the table—boiling—is so familiar to every one, and its effects are so uniform and apparently so simple, that few, I believe, have taken the trouble to inquire how or in what manner these effects are produced; and whether any, and what, improvements in that branch of cookery are possible. So little has this matter been an object of inquiry that few, very few, indeed, I believe, among the millions of persons who for so many ages have been daily employed in this process have ever given themselves the trouble to bestow one serious thought upon the subject.

"The cook knows from experience that if his joint of meat be kept a certain time immersed in boiling water it will be done, as it is called in the language of the kitchen; but if he be asked what is done to it, or how or by what agency the change it has undergone has been effected—if he understands the question—it is ten to one but he will be embarrassed. If he does not understand he will probably answer without hesitation, that 'The meat is made tender and eatable by being boiled.' Ask him if the boiling of the water be essential to the process. He will answer, 'Without doubt.' Push him a little further by asking him whether, were it possible to keep the water equally hot without boiling, the meat would not be cooked as soon and as well as if the water were made to boil. Here it is probable he will make the first step towards acquiring knowledge by learning to doubt."—COUNT RUMFORD, quoted by WILLIAMS in *Chemistry of Cookery,* ch. 2, p. 16. (A., 1900.)

1790. KNOWLEDGE, ANCIENT, OF THE HEAVENS — *Constellations Gradually Arranged.*—The primitive Greek sphere had become gradually filled with constellations, without being in any degree considered with relation to the ecliptic. Thus Homer and Hesiod designate by name individual stars and groups; the former mentions the constellation of the Bear ("otherwise known as the Celestial Wain, and which alone never sinks into the bath of Oceanos"), Bootes, and the Dog of Orion; the latter speaks of Sirius and Arcturus, and both refer to the Pleiades, the Hyades, and Orion. Homer's twice-repeated assertion, that the constellation of the Bear alone never sinks into the ocean, merely allows us to infer that in his age the Greek sphere did not yet comprise the constellations of Draco, Cepheus, and Ursa Minor, which likewise do not set. The statement does not prove a want of acquaintance with the existence of the separate stars forming these three catasterisms, but simply an ignorance of their arrangement into constellations. A long and frequently misunderstood passage of Strabo . . . specially proves . . . that in the Greek sphere the stars were only gradually arranged in constellations. Homer has been unjustly accused of ignorance, says Strabo, as if he had known of only one instead of two Bears. It is probable that the lesser one had not yet been arranged in a separate group, and that the name did not reach the Hellenes until after the Phenicians had specially designated this constellation, and made use of it for the purposes of navigation.—HUMBOLDT *Cosmos,* vol. iii, p. 119. (H., 1897.)

1791. KNOWLEDGE AND BELIEF —*Comparison to House and Furniture.*—Our beliefs must be carefully distinguished from our knowledge; and they seem to me to bear much the same relation to it that our furniture has to the building in which we put it. The walls are or ought to be solid and enduring; so is everything that deserves to be called knowledge. Each stone supports and is supported by the rest; and nothing but a weakness of its foundation or a decay of its material can make our fabric of thought uninhabitable. But the beliefs with which we furnish it have not the same durability. Adapted to meet our temporary needs, they may be either poor in material or but slightly put together. A carpet wears out, and, when past shifting and patching, must be replaced by a new one; a table or a chair breaks down, and, after successive repairs, is discarded as no longer serviceable. Or perhaps our requirements change; and some article which was at first made expressly in accordance with them proves no longer suitable to our needs; so that, finding it in our way, we wish to get rid of it. Some pieces of our furniture, again, originally of more substantial make, have become faded and old-fashioned; but they may be family heir-

looms, or we may have ourselves become attached to them; and so, not liking to discard them altogether, we put them away in some dark corner, or perhaps consign them to a seldom-visited lumber-room, where they rest almost forgotten in their obscurity. But at last some ray of sunshine throws a brighter light than usual upon our dark corner; or the opening of the shutters of our lumber-room lets into it the unwonted light of day; and we then find our old sofas and four-post beds so moth-eaten and decayed that we turn them out of our house instanter.—CARPENTER *Nature and Man*, lect. 7, p. 215. (A., 1889.)

1792. KNOWLEDGE A SAFEGUARD —*Biology Guards the Young against Pitfalls.*—If, however, the study of life-science has one prominent advantage over all other studies, it is that in its nature it acts most powerfully in bringing the present world and its constitution plainly and vividly before the eyes of boys and girls. It excites their interest in life and living things; it suggests trains of thought which extend almost into every department of knowledge which has a claim on human sympathy and regard. And it can provide the young with that knowledge of themselves which is the surest safeguard against the numerous pitfalls that in this exhausting age threaten the physical and mental health at every epoch of life.—ANDREW WILSON *Biology in Education*, p. 24. (Hum., 1888.)

1793. KNOWLEDGE, HUMAN, LIMITATIONS OF—*Science Enforces Lesson of Experience—Unseen Forces Control the World.*—It is evident that all the effects of the events with which we are concerned are not and could not possibly be perceived by us. We see and feel things—alike the great ones and the small ones, as we esteem them —only as they affect our senses; that is, only in small part and for a short time. They soon pass beyond our sight, and while they are within it they never show us all they are, often those which are the greatest seeming to us the least. How little we are able, often, to calculate the influence even upon our own future of events or actions of which we seem to have the most perfect knowledge at the time. And of the effects of these events on others, which must go on, so far as we can estimate, without any end, only the smallest fragment is within our view. It is one of the first lessons taught men by experience, not to judge of events by what they seem alone, but to remember that there may be much more involved in them than appears. To judge of our life, therefore, merely by that which is seen of it, is to commit ourselves to certain error. . . .

And this principle is established not only by experience; it is the lesson which, almost more than any other, science teaches us also. In exploring the material world, we soon find that, in order to understand any part of it aright, we must recognize things which are unseen, and have regard to conditions or to actions which do not come within our direct perception. It is enough to instance the pressure of the air, of which we have no consciousness; the motion of the earth, equally unperceivable by us; the hidden force, lurking in unseen atoms, of chemical affinity, or electricity; the vibrations which traverse the universal ether; and, in fine, that invisible unity which makes all her forces one, whereby (holding to the unseen) man has traced out in Nature a perfect order amid all confusion.—HINTON *The Mystery of Pain*, p. 15. (Hum., 1893.)

1794. ——— ——— *Tentative Explanations Alone Yet Possible of Volcanic Phenomena.*—That these operations, like all others going on upon the globe, are governed by great natural laws we cannot for a moment doubt. And that, in all probability, more careful and exact observation and reasoning will at some future time lead us to the recognition of these laws, every student of Nature is sanguine. But at the present time, it must be confessed, we are very far indeed from being able to afford that crowning proof of the truth of our theories of volcanic action which is implied in the power of predicting the period and degree of intensity of their manifestations. —JUDD *Volcanoes*, ch. 2, p. 32. (A., 1899.)

1795. KNOWLEDGE IS POWER— *For Nations as Well as Individuals.*—Bacon has said that, in human societies, knowledge is power. Both must rise and sink together. But the knowledge that results from the free action of thought is at once the delight and the indestructible prerogative of man; and in forming part of the wealth of mankind, it not unfrequently serves as a substitute for the natural riches, which are but sparingly scattered over the earth. Those states which take no active part in the general industrial movement, in the choice and preparation of natural substances, or in the application of mechanics and chemistry, and among whom this activity is not appreciated by all classes of society, will infallibly see their prosperity diminish in proportion as neighboring countries become strengthened and invigorated under the genial influence of arts and sciences.—HUMBOLDT *Cosmos*, vol. i, int., p. 53. (H., 1897.)

1796. KNOWLEDGE LIMITED BY PRECONCEPTIONS—When the question of the range of consciousness was first raised, these conditions [of the subjective and objective limitations of knowledge] were entirely overlooked, and the general method of investigation pursued was not one which could lead to any certain results. Conclusions were either deduced from certain metaphysical postulates—*e. g.*, that the mind, as a simple being, could only contain a single idea at a given moment—or the investigations were based solely on introspection.—WUNDT *Psychology*, lect. 16, p. 240. (Son. & Co., 1896.)

1797. KNOWLEDGE MADE PRACTICAL—*Daguerreotype Founded on Old-time Discovery.*—The fact that certain salts of silver were darkened by exposure to sunlight was known to the alchemists in the sixteenth century, and this observation forms the rudiment from which the whole art has been developed. The application of this fact to the production of pictures belongs, however, wholly to our own time. In the year 1802, Wedgewood described a mode of copying paintings on glass by exposure to light, but neither he nor Sir Humphry Davy could find any means of rendering the copies permanent. This was first effected in 1814 by M. Niepce, of Châlons, but no important results were obtained till 1839, when Daguerre perfected the beautiful process known as the daguerreotype. Permanent portraits were taken by him on silvered plates, and they were so delicate and beautiful that probably nothing in modern photography can surpass them. For several years they were the only portraits taken by the agency of light, but they were very costly, and were therefore completely superseded when cheaper methods were discovered.—WALLACE *The Wonderful Century,* ch. 5, p. 32. (D. M. & Co., 1899.)

1798. KNOWLEDGE, MAN YET BUT ON THRESHOLD OF—"*We Are Ancients of the Earth, in the Morning of the Times.*"* —We are in reality but on the threshold of civilization. Far from showing any indication of having come to an end, the tendency to improvement seems latterly to have proceeded with augmented impetus and accelerated rapidity. Why, then, should we suppose that it must now cease? Man has surely not reached the limits of his intellectual development, and it is certain that he has not exhausted the infinite capabilities of Nature. There are many things which are not as yet dreamt of in our philosophy: many discoveries which will immortalize those who make them, and confer upon the human race advantages which as yet, perhaps, we are not in a condition to appreciate. We may still say with our great countryman, Sir Isaac Newton, that we have been but like children playing on the seashore, and picking up here and there a smoother pebble or a prettier shell than ordinary, while the great ocean of truth lies all undiscovered before us.—AVEBURY *Prehistoric Times,* ch. 16, p. 575. (A., 1900.)

1799. KNOWLEDGE NOT SUFFICIENT FOR CONDUCT—*Right Desire the Chief Need.*—Right conduct is usually come short of more from defect of will than defect of knowledge. For the right coordination of those complex actions which constitute human life in its civilized form, there goes not only the prerequisite, recognition of the proper course, but the further prerequisite, a due impulse to pursue that course. On calling to mind our daily failures to fulfil often-repeated resolutions, we shall perceive that lack of the needful desire, rather than lack of the needful insight, is the chief cause of faulty action.—SPENCER *Biology,* pt. vi, ch. 13, p. 525. (A., 1900.)

1800. KNOWLEDGE OF FIRE UNIVERSAL AMONG MEN—It cannot be said to be satisfactorily proved that there is at present, or has been within historical times, any race of men entirely ignorant of fire. It is at least certain that as far back as the earliest Swiss lake villages and Danish shell-mounds the use of fire was well known in Europe.—AVEBURY *Prehistoric Times,* ch. 15, p. 535. (A., 1900.)

1801. "KNOWLEDGE OF THE CONSTRUCTION OF THE HEAVENS"—*The Ambition of the Elder Herschel—The Inquiring Spirit of Man.*—When we look around us into the regions which surround the solar system and see the myriads of myriads of stars which are spread through space, it is impossible not to feel strongly the desire to penetrate the mystery of the star-strewn depths. We have learned much respecting the earth on which we live, and not a little of the system to which the earth belongs. We have at least so far solved the problems presented to us by the planetary scheme as to recognize the subordinate position which our earth holds within it, and that the sun is the mighty ruler whose sway guides all the planets in their courses. But the inquiring spirit of man is not satisfied with these discoveries. No sooner has he learned to regard the earth as but one of a system of worlds circling round the sun, and that that system has such and such proportions, and presents such and such forms of motion, than he desires to regard our sun as but one of a system of suns, and to ascertain what may be the nature and the scale of this higher system, what the movements taking place within it. This was the noble problem which the elder Herschel set as the great end and aim of all his labors: "A knowledge of the construction of the heavens," he said, towards the end of his wonderful career as an observer, "has always been the ultimate object of my observations."—PROCTOR *Expanse of Heaven,* p. 256. (L. G. & Co., 1897.)

1802. LABOR ESSENTIAL TO HUMAN PROGRESS—*Rigorous Climates Stimulate—Improvement in Conditions and Results of Work—Evil with Good.*—We do not wish to draw upon ourselves the imputation of advocating the inevitable progress of the human race. The world is subject to evil

* "To sleep through terms of mighty wars,
And wake on science grown to more,
On secrets of the brain, the stars,
As wild as aught of fairy lore;
And all that else the years will show;
. . . . .
"Titanic forces taking birth
In divers seasons, divers climes,
For we are Ancients of the earth,
And in the morning of the times."
—TENNYSON *The Day-Dream, L'Envoi,* st. 1, ll. 9-20.

impressions as well as good, and whatever advance is made in the line of true progress will not be the result of a blind law of necessity, but of a providential design through human agency and properly directed human labor. Without labor nothing of value can be accomplished. It is the essential prerequisite of well-being, the original curse which proves a blessing in disguise. The remark has been properly made, that could all the wants of man be supplied without labor, there would be reason to fear that he would become a brute for the want of something to do, rather than a philosopher from an abundance of leisure. In all countries where Nature does the most, man does the least. The sterile soil and the inclement sky seem to be the stimulants to mental and physical exertion when once the necessary impulse has been given. True progress does not consist in obviating the necessity of labor, but in changing, by means of improvements in the arts, its character, in rendering it more conducive to the supply of the wants and comforts of man, and to the development of his mental and moral nature.—HENRY *Improvement of the Mechanical Arts (Scientific Writings,* vol. i, p. 323). (Sm. Inst., 1886.)

1803. LABOR, FALLACIES REGARDING—*"Free Labor" Often a Misnomer—Competition Despotic.*—Had not the working classes a right to employ their children as they pleased? Who were better able to judge, than fathers and mothers, of the capacities of their children? Why interfere for the protection of those who already had the best and most natural of all protections? Such were some of the arguments against interfering with "free labor." Now in what sense was this labor free? It was free from legal compulsion—that is to say, it was free from that kind of compulsion which arises out of the public will of the whole community imposed by authority upon the conduct of individuals. But there was another kind of force from which this labor was not free—the force of overpowering motive operating on the will of the laborers themselves. If one parent, more careful than others of the welfare of his children, and moved less exclusively by the desire of gain, withdrew his children at an earlier hour than others from factory work, his children were liable to be dismissed and not employed at all. On the other hand, motives hardly less powerful were in constant operation on the masters. The ceaseless, and increasing, and unrestricted competition amongst themselves—the eagerness with which human energies rush into new openings for capital, for enterprise, and for skill—made them, as a class, insensible to the frightful evils which were arising from that competition for the means of subsistence which is the impelling motive of labor. —ARGYLL *Reign of Law,* ch. 7, p. 210. (Burt.)

1804. LACK OF EVIDENCE NOT IMPEACHMENT OF EVIDENCE—*Manifest Adjustment Stands as Fact.*—The relations of adjustment between a given number of elements are none the less a certain fact because similar elements may be found elsewhere without any such adjustment being visible to us. It is the very fact of their not being separate, but combined, in the one case which justifies and compels a conclusion different from that which arises in the other case. This is the law of evidence on which we act and judge in other matters with conviction which is both intuitive and capable of being confirmed by the rules of reason. And this reply is applicable to all objections of the same kind. Those portions of the system of Nature which are wholly dark to us do not necessarily cast any shadow on those other portions of that system which are luminous with inherent light. Rather the other way. The shining tracts which thus reflect the light of reason and of mind send abundant rays into all the dark places round them.—ARGYLL *Reign of Law,* ch. 1, p. 21. (Burt.)

1805. LAKE-DWELLINGS OF LIVING PEOPLE—One feature in their [the Amazonian Indians'] mode of building deserves to be mentioned. Owing to the submerged state of the ground on which they live the Indians often raise their houses on piles sunk in the water. Here we have the old lacustrine buildings, so much discussed of late years, reproduced for us. One even sees sometimes a little garden lifted in this way above the water.—AGASSIZ *Journey in Brazil,* ch. 5, p. 162. (H. M. & Co., 1896.)

1806. LAKES HAVE LIFE-HISTORIES—*Duration Varying from a Day to Ages—The Oldest Lake Recent for the Geologist.*—Lakes, like mountains and rivers, have life-histories which exhibit varying stages from youth through maturity to old age. The span of their existence varies as do the lives of animals and plants. In arid regions they are frequently born of a single shower and disappear as quickly when the skies are again bright; their brief existence may be said to resemble the lives of the *Ephemera.* Again, the conditions are such that lakes perhaps hundreds of square miles in area are formed each winter, and evaporate to dryness during the succeeding summer; these may be compared with the annual plants, so regular are their periods. Still others exist for a term of years and only disappear during seasons of exceptional aridity; but the greater number of inland water bodies resemble the Sequoia and endure for centuries with but little apparent change. So long are the lives of many individuals that human history has recorded only slight changes in their outlines, but to the geologist even these are seen to be of recent origin and the day of their extinction not remote. —RUSSELL *Lakes of North America,* int., p. 7. (G. & Co., 1895.)

1807. LAMPS, CLASSICAL AND SAVAGE, ESSENTIALLY THE SAME—In all essential particulars the Eskimo woman's lamps at Bristol Bay are similar to the ones tended long ago in the Prytaneum at Athens and in the Temple of Vesta at Rome; and many hundreds of extremely rude examples are now in use all about the lands bordering on the Mediterranean.—MASON *Woman's Share in Primitive Culture,* ch. 5, p. 92. (A., 1894.)

1808. LAND, DWELLERS ON—*Changes beneath Sea Hard to Imagine—Stone Quarried for Distant Building.*—The first and greatest difficulty, then, consists in an habitual unconsciousness that our position as observers is essentially unfavorable when we endeavor to estimate the nature and magnitude of the changes now in progress. In consequence of our inattention to this subject we are liable to serious mistakes in contrasting the present with former states of the globe. As dwellers on the land, we inhabit about a fourth part of the surface, and that portion is almost exclusively a theater of decay and not of reproduction. We know, indeed, that new deposits are annually formed in seas and lakes, and that every year some new igneous rocks are produced in the bowels of the earth, but we cannot watch the progress of their formation; and as they are only present to our minds by the aid of reflection, it requires an effort both of the reason and the imagination to appreciate duly their importance. It is, therefore, not surprising that we estimate very imperfectly the result of operations thus invisible to us; and that, when analagous results of former epochs are presented to our inspection we cannot immediately recognize the analogy. He who has observed the quarrying of stone from a rock, and has seen it shipped for some distant port, and then endeavors to conceive what kind of edifice will be raised by the materials, is in the same predicament as a geologist who, while he is confined to the land, sees the decomposition of rocks and the transportation of matter by rivers to the sea, and then endeavors to picture to himself the new strata which Nature is building beneath the waters.—LYELL *Principles of Geology,* bk. i, ch. 5, p. 68. (A., 1854.)

1809. LAND FROM BENEATH THE WATERS *(Gen. i, 9; Ps. civ. 6-7).*—It results from the simplest methods of interpretation that, leaving out of view certain patches of metamorphosed rocks and certain volcanic products, all that is now dry land has once been at the bottom of the waters. It is perfectly certain that at a comparatively recent period of the world's history—the Cretaceous epoch—none of the great physical features which at present mark the surface of the globe existed. It is certain that the Rocky Mountains were not. It is certain that the Himalaya Mountains were not. It is certain that the Alps and the Pyrenees had no existence. The evidence is of the plainest possible character, and is simply this: We find raised up on the flanks of these mountains, elevated by the forces of upheaval which have given rise to them, masses of cretaceous rock which formed the bottom of the sea before those mountains existed. It is therefore clear that the elevatory forces which gave rise to the mountains operated subsequently to the Cretaceous epoch, and that the mountains themselves are largely made up of the materials deposited in the sea which once occupied their place.—HUXLEY *American Addresses,* lect. 1, p. 27. (A., 1898.)

1810. LANDSCAPE, PHYSIOGNOMY OF—*Each Geological Formation Marked by Features of Its Own.*—Physiognomy is no idle or doubtful science in connection with geology. The physiognomy of a country indicates, almost invariably, its geological character. There is scarce a rock among the more ancient groups that does not affect its peculiar form of hill and valley. Each has its style of landscape; and as the vegetation of a district depends often on the nature of the underlying deposits, not only are the main outlines regulated by the mineralogy of the formations which they define, but also in many cases the manner in which these outlines are filled up. The coloring of the landscape is well-nigh as intimately connected with its geology as the drawing.—MILLER *Old Red Sandstone,* ch. 11, p. 190. (G. & L., 1851.)

1811. LANDS, REMOTE, VISITED BY MIGRATING BIRDS—*Desolation of Arctic Regions in Winter.*—The chimney-swallow which in October was twittering under the eaves of the manor-house in Kent may possibly be recognizing the squire as he suns himself in the Algerine town which they have both chosen for their winter quarters, and the night-jar, which was in such a hurry to leave us that she had no time to build a nest, is perhaps a week after taking her departure from Surrey comparing notes with her vocal rivals among those palmetto groves beyond which peep the minarets of the Great Mosque of Morocco. In July every arctic cliff is moving with bird life; by October or November, at latest, the raven and the snowy owl are almost the only fowls left to give a semblance of the busy world to the snow wastes glittering under the cold moon and the weird-like northern lights.—BROWN *Nature-Studies,* p. 14. (Hum., 1888.)

1812. LANGUAGE AMONG THE LOWER ANIMALS—*Cooperation Involves Language—Rapid Communication among Ants—Antenna Language.*—Any means by which information is conveyed from one mind to another is language. And language existed on the earth from the day that animals began to live together. The mere fact that animals cling to one another, live together, move about together, proves that

they communicate. Among the ants, perhaps the most social of the lower animals, this power is so perfect that they are not merely endowed with a few general signs, but seem able to convey information upon matters of detail. Sweeping across country in great armies they keep up communication throughout the whole line, and succeed in conveying to one another information as to the easiest routes, the presence of enemies or obstacles, the proximity of food supplies, and even of the numbers required on emergencies to leave the main band for any special service. Every one has observed ants stop when they meet one another and exchange a rapid greeting by means of their waving antennæ, and it is possibly through these perplexing organs that definite intercourse between one creature and another first entered the world. The exact nature of the antenna language is not yet fathomed, but the perfection to which it is carried proves that the idea of language generally has existed in Nature from the earliest time.—DRUMMOND *Ascent of Man*, ch. 5, p. 157. (J. P., 1900.)

1813. LANGUAGE A SOURCE OF MYTH—*Confusion of Name Leads to Confusion of Nature—The Bernicle-tree and Its Progeny of Geese.*—Professor Max Müller, after discussing various theories of the origin of the barnacle myth [of the production of geese from barnacles] declares in favor of the idea that confusion of language and alteration of names lie at the root of the error. The learned author of the "Science of Language" argues that the true barnacles were named, properly enough, *Bernaculæ*, and lays stress on the fact that bernicle geese were first caught in Ireland. That country becomes *Hibernia* in Latin, and the Irish geese were accordingly named *Hibernicæ* or *Hiberniculæ*. By the omission of the first syllable—no uncommon operation for words to undergo—we obtain the name *Berniculæ* for the geese, this term being almost synonymous [or rather homonymous] with the name *Bernaculæ* already applied, as we have seen, to the barnacles. Bernicle-geese and bernicle-shells, confused in name, thus became confused in Nature; and, once started, the ordinary process of growth was sufficient to further intensify and render more realistic the story of the bernicle-tree and its wonderful progeny.—WILSON *Facts and Fictions of Zoology*, p. 8. (Hum., 1882.)

1814. LANGUAGE BANKS THE GAINS OF INTELLECT—*Progress Transmitted by Speech as Not by Heredity.*—When it is asked, What brought about this sudden rise of intelligence in the case of man? there is a wonderful unanimity among men of science as to the answer. It came about, it is supposed, in connection with the acquisition by man of the power to express his mind, that is to *speak*. Evolution, up to this time, had only one way of banking the gains it won—heredity. To hand on any improvement physically was a slow and precarious work. But with the discovery of language there arose a new method of passing on a step in progress. Instead of sowing the gain on the wind of heredity, it was fastened on the wings of words. The way to make money is not only to accumulate small gains steadily, but to put them out at a good rate of interest. Animals did the first with their mental acquisitions: man did the second. At a comparatively early date he found out a first-rate and permanent investment for his money, so that he could not only keep his savings and put them out at the highest rate of interest, but have a share in all the gain that was made by other men. That discovery was language.—DRUMMOND *Ascent of Man*, ch. 4, p. 150. (J. P., 1900.)

1815. LANGUAGE, BRUTES ATTAIN ONLY RUDIMENTS OF—*Word as Sign of Idea Only in Human Mind.*—As yet, however, no observer has been able to follow the workings of mind even in the dog that jumps up for food and barks for the door to be opened. It is hard to say how far the dog's mind merely associates jumping up with being fed, and barking with being let in, or how far it forms a conception like ours of what it is doing and why it does it. Anyhow, it is clear that the beasts and birds go so far in the natural language as to make and perceive gestures and cries as signals. But a dog's mind seems not to go beyond this point, that a good imitation of a mew leads it to look for a cat in the room; whereas a child can soon make out from the nurse saying "miaou" that she means something about some cat, which need not even be near by. That is, a young child can understand what is not proved to have entered into the mind of the cleverest dog, elephant, or ape, that a sound may be used as the sign of a thought or idea. Thus, while the lower animals share with man the beginnings of the natural language, they hardly get beyond its rudiments, while the human mind easily goes on to higher stages.—TYLOR *Anthropology*, ch. 4, p. 123. (A., 1899.)

1816. LANGUAGE CONTINUALLY GENERATED—*A Living Force—Writing vs. Speech.*—The true solution of the contrasting stability and fluctuation that we find in language lies in the unity of human nature. No one assigns to a word precisely the same meaning that another does, and a shade of meaning, be it ever so slight, ripples on like a circle in the water through the entirety of language. Even the preservation of a language by means of writing keeps it only in an incomplete way, mummy-like, in which it can only gain vitality by means of timely recitation. In itself it is not a completed work, but an internal energy in the soul begetting new creations.—WILHELM VON HUMBOLDT *Ueber die Verschiedenheit des menschlichen Sprachbaues und ihren Einfluss auf*

die geistige Entwickelung des Menschengeschlechts. (Translated for *Scientific Side-Lights.)*

1817. LANGUAGE CONTROLS CUSTOMS AND TRADE—The French language produces French habits, French habits introduce French products. Those who know French become the patrons of France.—*Bulletin de l'Alliance française.* (Translated for *Scientific Side-Lights.)*

1818. LANGUAGE, GRADUAL ACQUISITION OF—*Vocabulary of English Language—Number of Words in Common Use—Vocabulary Varies with Education.*—The vocabulary of a rich and long-cultivated language like the English may be roughly estimated at about 100,000 words (altho this excludes a great deal which, if "English" were understood in its widest sense, would have to be counted in): but thirty thousand is a very large estimate for the number ever used, in writing or speaking, by a well-educated man: three to five thousand, it has been carefully estimated, cover the ordinary needs of cultivated intercourse; and the number acquired by persons of lowest training and narrowest information is considerably less than this. Nowhere more clearly than here does it appear that one gets his language by a process of learning, and only thus: for all this gradual increase of one's linguistic resources goes on in the most openly external fashion, by dint of hearing and reading and study; and it is obviously only a continuation, under somewhat changed circumstances, of the process of acquisition of the first nucleus: while the whole is parallel to the beginning and growth of one's command of a "foreign" tongue.—WHITNEY *Life and Growth of Language,* ch. 2, p. 26. (A., 1900.)

1819. LANGUAGE INVOLVES ENTIRE MIND—*No Single Faculty Competent to the Work.*—Its [phrenology's] "faculties," as a rule, are fully equipped persons in a particular mental attitude. Take, for example, the "faculty" of language. It involves in reality a host of distinct powers. We must first have images of concrete things and ideas of abstract qualities and relations; we must next have the memory of words and then the capacity so to associate each idea or image with a particular word that, when the word is heard, the idea shall forthwith enter our mind. We must, conversely, as soon as the idea arises in our mind, associate with it a mental image of the word, and by means of this image we must innervate our articulatory apparatus so as to reproduce the word as physical sound. To read or to write a language, other elements still must be introduced. But it is plain that the faculty of spoken language alone is so complicated as to call into play almost all the elementary powers which the mind possesses—memory, imagination, association, judgment, and volition. A portion of the brain competent to be the adequate seat of such a faculty would needs be an entire brain in miniature—just as the faculty itself is really a specification of the entire man.—JAMES *Psychology,* vol. i, ch. 2, p. 28. (H. H. & Co., 1899.)

1820. LANGUAGE MADE MEANINGLESS BY AUTOMATIST THEORY—*"Ought" — "Duty" — "Responsibility"—Individual Deemed Victim of Circumstances.*—It seems to me . . . quite clear that on the automatist or determinist theory, such words as "ought," "duty," "responsibility," have to be used, if used at all, in new significations. The welfare of that aggregate of automata which we call "society" may require that every individual automaton shall be prevented from doing what is injurious to it; and punishment for offenses actually committed may be reasonably inflicted as a deterrent from the repetition of such offenses by the individual or by others. But if the individual has in himself no power either to do the right or to avoid the wrong, and if the potency of that aggregate of feelings about actions as being "right or wrong," which is termed "conscience," entirely depends upon "circumstances" over which he neither has nor ever has had any control, I fail to see in what other sense he should be held "responsible" for doing what he knows that he "ought not" to have done, or for not doing what he knows that he "ought" to have done, than a steam-engine, which breaks away from its "governor" in consequence of a sudden increase of steam-pressure, or which comes to a stop through the bursting of its steam-pipe, can be accounted responsible for the damage thence arising.—CARPENTER *Mental Physiology,* pref., p. 46. (A., 1900.)

1821. LANGUAGE MAKES KNOWLEDGE HEREDITARY—*The Son Begins Where the Father Ends.*—Language formed the trellis on which mind climbed upward, which continuously sustained the ripening fruits of knowledge for later minds to pluck. Before the savage's son was ten years old he knew all that his father knew. The ways of the game, the habits of birds and fish, the construction of traps and snares—all these would be taught him. The physical world, the changes of season, the location of hostile tribes, the strategies of war, all the details and interests of savage life would be explained. And before the boy was in his teens he was equipped for the struggle for life as his forefathers had never been even in old age. The son, in short, started to evolve where his father left off. Try to realize what it would be for each of us to begin life afresh, to be able to learn nothing by the experiences of others, to live in a dumb and illiterate world, and see what chance the animal had of making pronounced progress until the acquisition of speech.—DRUMMOND *Ascent of Man,* ch. 4, p. 152. (J. P., 1900.)

1822. LANGUAGE, MYSTERY OF— There could be no invention of language unless its type already existed in the human understanding. Man is man only by means of speech, but, in order to invent speech, he must be already man.—WILHELM VON HUMBOLDT *Einleitung, Ueber die Kawi-sprache auf der Insel Java.* (Translated for *Scientific Side-Lights.)*

1823. LANGUAGE OF ANIMALS MERELY RUDIMENTARY— Animals possess certain elements of language, just as they possess certain elements of consciousness which might serve as the basis of intellectual function, but they do not possess language itself. So that the mere absence of this external mark would justify us in inferring the absence of those mental functions of which it is the mark. As a rule, it is not any physical obstacle, as is so often thought, which prevents animals from talking. In very many animals the development of the organs of speech has gone far enough to enable them to clothe thought in words, if the thought were there to clothe. The question why the animals do not talk is most correctly answered in the old way—because they have nothing to say. Only we must add that certain movements and sounds characteristic of feelings and ideas seem to be the forerunners of language, and that animals give signs that in this connection, as in others, their mental life is the immediate precursor of our own.—WUNDT *Psychology,* lect. 24, p. 363. (Son. & Co., 1896.)

1824. LANGUAGE OF EXPRESSION, NATURAL— *Emotion Manifested through the Body.*—It has been noted in all ages and countries that the feelings possess a natural language or expression. So constant are the appearances characterizing the different classes of emotions that we regard them as a part of the emotions themselves. The smile of joy, the puckered features in pain, the stare of astonishment, the quivering of fear, the tones and glance of tenderness, the frown of anger, are united in seemingly inseparable association with the states of feeling that they indicate. If a feeling arises without its appropriate sign or accompaniment, we account for the failure either by voluntary suppression or by the faintness of the excitement, there being a certain degree or intensity requisite to affect the bodily organs. On this uniformity of connection between feelings and their bodily expression depends our knowledge of each other's mind and character. When any one is pleased, or pained, or loving, or angry, unless there is purposed concealment we are aware of the fact, and can even estimate in any given case the degree of the feeling.—BAIN *Mind and Body,* ch. 2, p. 2. (Hum., 1880.)

1825. LANGUAGE OF GESTURE— *Natural Signs Understood by All Races of Men.*—Communication by gesture signs between persons unable to converse in vocal language is an effective system of expression common to all mankind. Thus the signs used to ask a deaf-and-dumb child about his meals and lessons, or to communicate with a savage met in the desert about game or enemies, belong to codes of gesture signals identical in principle and to a great extent independent both of nationality and education; there is even a natural syntax, or order of succession, in such gesture signs. To these gestures let there be added the use of the interjectional cries, such as *oh! ugh! hey!* and imitative sounds to represent the cat's *mew,* the *click* of a trigger, the *clap* or *thud* of a blow, etc. The total result of this combination of gesture and significant sound will be a general system of expression, imperfect but serviceable, and naturally intelligible to all mankind without distinction of race. . . . The lower animals make no approach to the human system of natural utterance by gesture signs and emotional-imitative sounds, while the practical identity of this human system among races physically so unlike as the Englishman and the native of the Australian bush indicates extreme closeness of mental similarity throughout the human species. —DANIEL WILSON *Anthropology,* ch. 6, p. 22. (Hum., 1885.)

1826. LANGUAGE OF TOUCH— *Ants Communicate by Antennæ.*—Language is the key to the union we remark in this numerous family. It is not by means of sounds or visible signs, but by touch, that it manifests itself; it is especially the antennæ, those organs that distinguish insects from all other animals, that serve, whenever the species meets in society, the noble use of communicating impressions from one individual to another, their wishes, necessities, and the situation. No doubt the antennal language is imperfect, if compared with our requirements, but it suffices very well for ants.—HUBER *Recherches sur les Mœurs des Fourmis indigènes,* p. 310. (Translated for *Scientific Side-Lights.)*

1827. LANGUAGE, PLACE OF, IN EARLY EDUCATION— The several faculties of the human mind are not simultaneously developed, and in educating an individual we ought to follow the order of Nature, and to adapt the instruction to the age and mental stature of the pupil. If we reverse this order and attempt to cultivate faculties which are not sufficiently matured, while we neglect to cultivate those which are, we do the child an irreparable injury. Memory, imitation, imagination, and the faculty of forming mental habits exist in early life, while the judgment and the reasoning powers are of slower growth. It is a fact abundantly proved by observation that the mere child, by the principle which has been denominated sympathetic imitation, may acquire the power of expressing his desires and emotions in correct and even beautiful language without knowing or being able to comprehend the simplest principles

of philology. He even seizes, as if by a kind of instinct, upon abstract terms, and applies them with ease and correctness; but as life advances, the facility of verbal acquisition declines, and with some it entirely disappears. Hence the plan appears to me to be wise and in accordance with Nature, which makes the acquisition of language an essential part of early elemental education. The same child which acquires almost without effort his vernacular tongue may by a similar process be taught to speak the principal ancient and modern languages.—HENRY *Thoughts on Education (Scientific Writings*, vol. i, p. 335). (Sm. Inst., 1886.)

1828. LANGUAGE, PROCESS OF CHANGE IN—The organs of speech are differently framed by Nature in different climates and countries; and even in the same countries some men pronounce their words broader, softer, harder, quicker, or slower than others, and some are unable to pronounce this or that letter. These accidents, by example and imitation, bring on a change of vowels and consonants, whence a language becomes unlike what it was at first.—*Preface to Boucher's Dictionary.* (Translated for *Scientific Side-Lights.)*

1829. LANGUAGE, RACE-STRUGGLES FOR EXTENSION OF—*German and Slav Contend for Control of Education.*—The Germans are doing among the Slavs what the French are doing in Syria. Both in Germany and Austria they have societies called German school associations. They establish schools in Bohemia, in Moravia, in Styria, and elsewhere, seeking to attract to them the Slav children by means of gratuities, good organization of the instruction, hygienic management of the buildings, etc. The expenses of these schools are covered by assessment of the members of the association. Naturally the Slavs resist, and in order to struggle against the Germans they also found societies of the same kind to maintain Slav schools. In this struggle evidently the school that is most perfect will triumph in the long run. And this will displace the linguistic frontier to the profit of the nation that is most energetic. Aside from the schools, societies of all kinds are being formed for the propaganda of a language, such, for example, as the *Alliance française*, which has been in existence since 1883.—NOVICOW *Les Luttes entre Sociétés humaines*, p. 101. (Translated for *Scientific Side-Lights.)*

1830. LANGUAGE, THE EVOLUTION OF—*Archbishop Trench—How Language is Divine—God Gave, Not Names, but a Power of Naming (Gen. ii, 19-20)—Man Not a Parrot.*—Even Trench at this point succumbs to the theory of development, and his testimony is the more valuable that it is evidently so very much against the grain to admit it. He begins by stating apparently the opposite: "The truer answer to the inquiry how language arose is this: God gave man language just as he gave him reason, and just because he gave him reason; for what is man's *word* but his *reason* coming forth that it may behold itself? They are indeed so essentially one and the same that the Greek language has one word for them both. He gave it to him because he could not be man—that is, a social being—without it." Yet he is too profound a student of words to fail to qualify this. . . . "Yet," he continues, "this must not be taken to affirm that man started at the first furnished with a full-formed vocabulary of words, and, as it were, with his first dictionary and first grammar ready made to his hands. He did not thus begin the world with *names*, but *with the power of naming:* for man is not a mere speaking machine; God did not teach him words, as one of us teaches a parrot, from without, but gave him a capacity, and then evoked the capacity which he gave" [Trench, "The Study of Words," pp. 14-15].—DRUMMOND *Ascent of Man*, ch. 5, p. 177. (J. P., 1900.)

1831. LANGUAGE THE NATURAL STUDY OF CHILDHOOD—*Science Requires Maturity of Mind.*—The study of language should be prosecuted in childhood, as it is, in fact, in the acquisition of the mother-tongue. . . . The memory for words should be exercised and stimulated. Choice tales, poems (narrative and lyric) should be learned for recitation. Natural history in all its branches, as contrasted with the sciences of Nature or scientific physics, should be mastered with the objects before the eye—flowers, minerals, shells, birds, and beasts. These studies should all be mastered in the springtime of life, when the tastes are simple, the heart is fresh, and the eye is sharp and clear. The facts of history and geography should be fixed by repetition and stored away in order. But science of every kind—whether of language, of Nature, of the soul, or of God—as science, should not be prematurely taught. For the consequence is either disgust and hostility to all study, on the one hand, or, on the other, superficial thinking, presumptuous conceit, and, worst of all, sated curiosity. The law of intellectual progress involves effort and discipline severely imposed and constantly maintained, but the effort and discipline should follow the guidance of Nature.—PORTER *Human Intellect*, § 61, p. 74. (S., 1893.)

1832. LANGUAGE, THE SCIENCE OF, UNITES THE AGES—*Value of Philology.*—Philology recognized its calling to be mediator between the remotest ages, to afford us the enjoyment of preserving through thousands of years an unbroken identity with the noblest and greatest nations of the world, by familiarizing us through the medium of grammar and history with the works of their minds and the course of their

destinies, as if there were no gulf to divide us from them.—NIEBUHR *Römische Geschichte*, preface. (Translated for *Scientific Side-Lights.)*

1833. LANGUAGE UNFOLDED FROM DEPTHS OF THOUGHT — Languages, as intellectual creations of man, and as closely interwoven with the development of mind, are, independently of the national form which they exhibit, of the greatest importance in the recognition of similarities or differences in races. This importance is especially owing to the clew which a community of descent affords in threading that mysterious labyrinth in which the connection of physical powers and intellectual forces manifests itself in a thousand different forms. . . . Language is a part and parcel of the history of the development of mind; and however happily the human intellect, under the most dissimilar physical conditions, may unfettered pursue a self-chosen track, and strive to free itself from the dominion of terrestrial influences, this emancipation is never perfect. There ever remains, in the natural capacities of the mind, a trace of something that has been derived from the influences of race or of climate, whether they be associated with a land gladdened by cloudless azure skies or with the vapory atmosphere of an insular region. As, therefore, richness and grace of language are unfolded from the most luxuriant depths of thought, we have been unwilling wholly to disregard the bond which so closely links together the physical world with the sphere of intellect and of the feelings by depriving this general picture of Nature of those brighter lights and tints which may be borrowed from considerations, however slightly indicated, of the relations existing between races and languages.—HUMBOLDT *Cosmos*, vol. i, p. 357. (H., 1897.)

1834. LANGUAGE, VALUE OF THE STUDY OF—*Versatility and Flexibility of Mind—The End To Be Aimed at in Secondary Instruction.*—All experts agree that the preparatory training of students of the gymnasium is superior to that of those who graduate from any other institution of learning, because it produces greater facility in the faculty of thinking, furnishing more power in finding one's way in the domain of the various new disciplines that are taken up. If that is true—and the fact cannot be denied—the reason for it can only be traced to the language-instruction which is the thing that distinguishes the plan of instruction in the gymnasium from the other secondary schools. And, in fact, instruction in language can be designated a most eminent means of training. . . . By means of it the student attains a certain versatility and flexibility of mind that enable him always to find his way in those forms of thought best corresponding to the specific departments of knowledge or to the fields of research.—KLEINWÄCHTER *Zur Frage des naturwissenschaftlichen Unterrichts (Deutsche Zeit- und Streit-Fragen*, p. 246). (Translated for *Scientific Side-Lights.)*

1835. LANGUAGE WOMAN'S SPECIALTY—*Source of Man's Taciturnity.*—The Mexicans say, "A woman is the best dictionary." This unpremeditated confession is based upon an early induction made by the aborigines of that country centuries ago. Savage men, in hunting and fishing, are much alone, and have to be quiet, hence their taciturnity; but women are together, and chatter all day long. Away from the centers of culture women are still the best dictionaries, talkers, and letter-writers.—MASON *Woman's Share in Primitive Culture*, ch. 9, p. 190. (A., 1894.)

1836. LAVA, CAVERNS IN—*Subterranean Grottoes and Vaults of Etna.*—Mention was made of the entrance of a lava-stream into a subterranean grotto, whereby the foundations of a hill were partially undermined. Such underground passages are among the most curious features on Ætna, and appear to have been produced by the hardening of the lava during the escape of great volumes of elastic fluids, which are often discharged for many days in succession after the crisis of the eruption is over. Near Nicolosi, not far from Monti Rossi, one of these great openings may be seen, called the Fossa della Palomba, 625 feet in circumference at its mouth, and seventy-eight deep. After reaching the bottom of this we enter another dark cavity, and then others in succession, sometimes descending precipices by means of ladders. At length the vaults terminate in a great gallery ninety feet long and from fifteen to fifty broad, beyond which there is still a passage never yet explored, so that the extent of these caverns remains unknown. The walls and roofs of these great vaults are composed of rough and bristling scoriæ of the most fantastic forms. —LYELL *Principles of Geology*, bk. ii, ch. 25, p. 401. (A., 1854.)

1837. LAW AS AN OBSERVED ORDER OF FACTS—*Cause of Chemical Phenomena Unknown.*—The first and, so to speak, the lowest sense in which law is applied to natural phenomena is that in which it is used to express simply "an observed order of facts"—that is to say, facts which under the same conditions always follow each other in the same order. In this sense the laws of Nature are simply those facts of Nature which recur according to a rule. It is not necessary to the legitimate application of law in this sense that the cause of any observed order of facts should be at all known or even guessed at. The force or forces to which that order is due may be hid in total darkness. . . . A very large proportion of the laws of every science are laws of this kind and in this sense. For example, in chemistry the behavior of different substances towards each other, in re-

spect to combination and affinity, is reduced to system under laws of this kind, and of this kind only. Because, altho there is a probability that electric or galvanic force is the cause or one of the causes of the series of facts exhibited in chemical phenomena, this is as yet no better than a probability, and the laws of chemistry stand no higher than facts which by observation and experiment are found to follow certain rules.—ARGYLL *Reign of Law*, ch. 2, p. 40. (Burt.)

1838. LAW CONSISTENT WITH DESIGN—*Will Adapts Natural Laws to Its Purpose.*—Our own experience shows that the universal reign of law is perfectly consistent with a power of making those laws subservient to design—even when the knowledge of them is but slight, and the power over them slighter still. How much more easy, how much more natural, to conceive that the same universality is compatible with the exercise of that Supreme Will before which all are known and to which all are servants! What difficulty in this view remains in the idea of the Supernatural? Is it any other than the difficulty in believing in the existence of a Supreme Will—in a living God?—ARGYLL *Reign of Law*, ch. 1, p. 13. (Burt.)

1839. LAW DOES NOT NEGLECT THE LEAST—*Gravitation Holds Even Microscopic Germs.*—The influence of gravity upon bacteria in the air may be observed in various ways, in addition to its action within a limited area like a sewer or a room. Miquel found in some investigations in Paris that, whereas on the Rue de Rivoli 750 germs were present in a cubic meter, yet at the summit of the Panthéon only 28 were found in the same quantity of air. At the tops of mountains air is germ-free, and bacteria increase in proportion to descent. As Tyndall has pointed out, even ultramicroscopic cells obey the law of gravitation. This is equally true in the limited areas of a laboratory or warehouse and in the open air.—NEWMAN *Bacteria*, ch. 3, p. 106. (G. P. P., 1899.)

1840. LAW EXALTS PHENOMENA—*The Same Smoke Column Blue and Red.*—Touched by the wand of law, the dross of facts becomes gold, the meanest being raised thereby to brotherhood with the highest. Thus the smoke of an Irish cabin lifts our speculations to the heavenly dome. . . . The selfsame column of smoke may be projected against a bright and a dark portion of the same cloud, and thus made to appear blue and red at the same time. The blue belongs to the light reflected from the smoke; the red to the light transmitted through it. In like manner the hues of the atmosphere are not due to coloring matter, but to the fact of its being a turbid medium. Through this we look at the blackness of unillumined space and see the blue at the western heaven at sunset, and meet that light which steeps the clouds of evening in orange and crimson dyes.—TYNDALL *Hours of Exercise in the Alps (Notes, etc., Killarney)*, p. 420. (A., 1898.)

1841. LAW HOLDS EVEN THE WANDERING COMETS—*They Move Obedient to the Primal Impulse and Gravitation—Comets of Solar System, Perhaps Expelled from Giant Planets.*—Since these comets are associated in so peculiar a manner with the giant planets [Jupiter, Saturn, Uranus, and Neptune] of the solar system, may it not be that they bear a relation to these planets somewhat resembling that which the large comets bear to the suns which people space? As the large comets would seem to have been expelled from these suns, may not the small comets have been expelled from the giant planets? We need not necessarily assume that these giant planets are still in the active and sunlike state necessary, we may suppose, for the expulsion of comets. . . . It may be that the birth of the comet families of the giant planets took place in far distant eras when these orbs were not merely, as now, instinct with an intense heat, but also aglow with light, so as to present, when viewed from other systems, the aspect which the small companions of unequal double stars present to our telescopists.—PROCTOR *Expanse of Heaven*, p. 156. (L. G. & Co., 1897.)

1842. LAW IN LEAF-MOVEMENTS—*Leaves Vertical in Sleeping Plants.*—Leaves, when they go to sleep, move either upwards or downwards, or, in the case of the leaflets of compound leaves, forwards, that is, towards the apex of the leaf, or backwards, that is, towards its base; or, again, they may rotate on their own axes without moving either upwards or downwards. But in almost every case the plane of the blade is so placed as to stand nearly or quite vertically at night. Therefore the apex, or the base, or either lateral edge may be directed towards the zenith. Moreover, the upper surface of each leaf, and more especially of each leaflet, is often brought into close contact with that of the opposite one; and this is sometimes effected by singularly complicated movements. This fact suggests that the upper surface requires more protection than the lower one.—DARWIN *Power of Movement in Plants*, ch. 6, p. 281. (A., 1900.)

1843. LAW INVARIABLE UNDER SAME CONDITIONS—*Variable When Conditions Vary—Purpose Adapted to Changed Relations.*—We hear of rigid and universal sequence—necessary—invariable; of unbroken chains of cause and effect, no link of which can, in the nature of things, be ever broken. And this idea grows upon the mind, until in some confused manner it is held as casting out the idea of purpose in creation, and inconsistent with the element of will. If it be so, the difficulty cannot be evaded by denying the uniformity, any more than the universality, of law. It is perfectly true that every law is in its own nature invari-

able, producing always precisely and necessarily the same effects—that is, provided it is worked under the same conditions. But then, if the conditions are not the same the invariableness of effect gives place to capacities of change which are almost infinite. It is by altering the conditions under which any given law is brought to bear, and by bringing other laws to operate upon the same subject, that our own wills exercise a large and increasing power over the material world. And be it observed—to this end the uniformity of laws is no impediment, but, on the contrary, it is an indispensable condition. Laws are in themselves—if not unchangeable—at least unchanging, and if they were not unchanging they could not be used as the instruments of will. If they were less rigorous they would be less certain, and the least uncertainty would render them incapable of any service. No adjustment, however nice, could secure its purpose if the implements employed were of uncertain temper.

The notion, therefore, that the uniformity or invariableness of the laws of Nature cannot be reconciled with their subordination to the exercise of will, is a notion contrary to our own experience.—ARGYLL *Reign of Law*, ch. 2, p. 58. (Burt.)

1844. LAW OF CONSTANCY OR CONTINUITY—*Exemplified by Action of the Voltaic Battery—Effect Exerted at a Distance from the Cause.*—Before you is an instrument—a small voltaic battery—in which zinc is immersed in a suitable liquid. An attractive force is at this moment exerted between the metal and the oxygen of the liquid, actual union, however, being in the first instance avoided. Uniting the two ends of the battery by a thick wire, the attraction is satisfied, the oxygen unites with the metal, zinc is consumed, and heat, as usual, is the result of the combustion. A power which, for want of a better name, we call an electric current, passes at the same time through the wire. Cutting the thick wire in two, let the severed ends be united by a thin one. It glows with a white heat. . . . Suppose in the first instance, when the thick wire is employed, that we permit the action to continue until 100 grains of zinc are consumed, the amount of heat generated in the battery would be capable of accurate numerical expression. Let the action then continue, with the thin wire glowing, until 100 grains of zinc are consumed. . . . The amount of heat generated in the battery . . . will be less by the precise amount generated in the thin wire outside the battery. In fact, by adding the internal heat to the external, we obtain for the combustion of 100 grains of zinc a total which never varies. We have here a beautiful example of that law of constancy as regards natural energies, the establishment of which is the greatest achievement of modern scientific philosophy. By this arrangement, then, we are able to burn our zinc at one place, and to exhibit the effects of its combustion at a distance. In New York, for example, we may have our grate and fuel; but the heat and light of our fire may be made to appear at San Francisco.—TYNDALL *Lectures on Light*, lect. 1, p. 6. (A., 1898.)

1845. ——— ——— *Suddenness in Nature—Lightning—Chemical Combination.*—The same ultimate conceptions, and no other, appear to constitute all the truth that is to be found in a favorite doctrine among the cultivators of physical science—the so-called "Law of Continuity." This phrase is indeed often used with such looseness of meaning that it is extremely difficult to understand the primary signification attached to it. One common definition, or rather one common illustration, of this law is said to be that Nature does nothing suddenly—nothing "*per saltum*" [literally, by a leap]. Of course, this can only be accepted under some metaphorical or transcendental meaning. In Nature there is such a thing as a flash of lightning, and this is generally recognized as sufficiently sudden. . . . The action of chemical affinity is always rapid, and very often even instantaneous. Yet these are among the most common and the most powerful factors in the mechanism of Nature. They have the most intimate connection with the phenomena of life, and we know only too well that in these the profoundest changes are often determined in moments of time. For many purposes to which this so-called "Law of Continuity" is often applied in argument no idler dogma was ever invented in the schools.—ARGYLL *Unity of Nature*, ch. 4, p. 83. (Burt.)

1846. LAW OF DEATH—*Natural Tendencies to Dissolution—Life a Temporary Resistance of Disorganizing Forces.*—There is in every living organism a law of death. We are wont to imagine that Nature is full of life. In reality it is full of death. One cannot say it is natural for a plant to live. Examine its nature fully, and you have to admit that its natural tendency is to die. It is kept from dying by a mere temporary endowment, which gives it an ephemeral dominion over the elements—gives it power to utilize for a brief span the rain, the sunshine, and the air. Withdraw this temporary endowment for a moment and its true nature is revealed. Instead of overcoming Nature it is overcome. The very things which appeared to minister to its growth and beauty now turn against it and make it decay and die. The sun which warmed it withers it; the air and rain which nourished it rot it. It is the very forces which we associate with life which, when their true nature appears, are discovered to be really the ministers of death.—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 92. (H. Al.)

1847. LAW OF GROWTH IN STRUCTURE OF THE EARTH—Formerly men looked upon the earth as a unit in time, as

the result of one creative act, with all its outlines established from the beginning. It has been the work of modern science to show that its inequalities are not contemporaneous or simultaneous, but successive, including a law of growth—that heat and cold, and the consequent expansion and contraction of its crust, have produced wrinkles and folds upon the surface, while constant oscillations, changes of level which are even now going on, have modified its conformation, and molded its general outline through successive ages. — AGASSIZ *Geological Sketches*, ser. i. ch. 4. p. 98. (H. M. & Co., 1896.)

1848. LAW OF MAN TO FOLLOW LAW OF NATURE—*Control by Change of Conditions—A Recent Conception.*—Just as the will of the individual can operate upon itself by the use of means, some of which are known instinctively, whilst others are found out by reason; so can the collective will of society operate upon the conduct of its members in two ways—first, directly by authority; and secondly, indirectly by altering the conditions out of which the most powerful motives spring. This last is a principle of government which has been distinctly recognized only in modern times, and which admits of applications not yet foreseen. The idea of founding human law upon the laws of Nature is an idea which, tho sometimes instinctively acted upon, was never systematically entertained in the ancient world. Indeed, the true conception of natural law is one founded on the progress of physical investigation, and growing out of the habits of scientific thought.—ARGYLL *Reign of Law*, ch. 7, p. 194. (Burt.)

1849. LAW, ORDINARY ACTION OF, REVERSED—*Death by Falling Upwards—Peculiar Peril of Deep-sea Fish.*—The fish that live at these enormous depths are, in consequence of the enormous pressure, liable to a curious form of accident. If, in chasing their prey or for any other reason, they rise to a considerable distance above the floor of the ocean, the gases of their swimming-bladder become considerably expanded and their specific gravity very greatly reduced. Up to a certain limit the muscles of their bodies can counteract the tendency to float upwards and enable the fish to regain its proper sphere of life at the bottom; but beyond that limit the muscles are not strong enough to drive the body downwards, and the fish, becoming more and more distended as it goes, is gradually killed on its long and involuntary journey to the surface of the sea. The deep-sea fish, then, are exposed to a danger that no other animals in this world are subject to, namely that of tumbling upwards.

That such accidents do occasionally occur is evidenced by the fact that some fish, which are now known to be true deep-sea forms, were discovered dead and floating on the surface of the ocean long before our modern investigations were commenced.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 21. (A., 1894.)

1850. LAW, UNIVERSAL — *Courses of Shooting-stars Obey—Why Not Each Human Life?*—Such is the course of these minute shooting-stars, a course now perfectly determined. A lesson as profound as unexpected, the shooting-star itself does not glide by chance, borne along by an arbitrary wind; it describes a mathematical orbit as well as the earth or the colossal Jupiter. All is ruled, decreed by the supreme Law; and—who knows?—perhaps each of our frail existences, each of our ephemeral actions, is also determined by the invisible Nature which places the star in the sky, the infant in the cradle, the old man in the tomb.—FLAMMARION *Popular Astronomy*, bk. v, ch. 4. p. 541. (A.)

1851. ——— ——— *Holds Every Particle of Matter—The Lost Comet—Every Fragment Would Follow Path of Total Mass.*—Since the comet [Biela's] was last seen it has thrice traversed the enormous orbit here described, passing from a least distance of about eighty millions of miles to its greatest distance, amounting nearly to six hundred millions of miles. Whether it has been destroyed as a comet, or whether it has only been so far dissipated as to be invisible in our most powerful telescopes, we do not know. But in either case it has pursued the same general course, for the minutest fragment of its substance would obey as implicitly the law of gravity as the once complete comet, or even as the staider members of the solar family—the planets.—PROCTOR *Expanse of Heaven*, p. 132. (L. G. & Co., 1897.)

1852. LAWS, DESIGN TRANSFERRED FROM PHENOMENA TO—The question now before us—whether the evidences of intelligent design, which theology has hitherto recognized in the structure of organized beings, are or are not any longer tenable, when viewed under the new light thrown upon them by the Darwinian lamp—is one which, tho science has much to say upon it, it is beyond the province of science to decide. Newton and Laplace were both accused of atheism by their contemporaries for setting up their own conceptions in the place of the action of the Creator; and you well know that the same charge has been brought against Darwin. I shall endeavor to show you that in his case, as in that of his great predecessors, the real result of his scientific work has been to effect for biology what they are well said by Dr. Whewell to have effected for astronomy—the "transfer of the notion of design and end from the region of facts to that of laws."—CARPENTER *Nature and Man*, lect. 15, p. 413. (A., 1889.)

1853. LAWS, INDUSTRIAL AND MORAL—*In All Industries Man Is Still Man.*—We do not regard the industrial life as

isolated, nor as the isolated result of specifically economic forces having natural laws peculiar to itself. The industrial life is a free product of the human spirit; the total industrial activity of a people is only one side of the national life standing in the closest causal relations with the other phenomena of the national spirit; the industrial forces are general forces working in man and in Nature, which are only producing particular forms, and in these forms particular effects. Above all things we emphasize that our dealings are with persons, with people who, being active in the family, the state, and society, are also active industrially; but with people who are not something else in this department than they are elsewhere. And for that reason we do not recognize any motives that are peculiarly industrial, and cannot admit that industrial life is a domain to which the general moral teachings and the categorical imperative of moral duty do not apply. On the contrary we affirm that the moral law and devotion to moral duty must become the determining force here also as well as in the remainder of the national life, if society is to develop prosperous conditions.

Our so-called laws are historic and relative, our solutions are relative, only possible of execution by means of exact information, of consideration of the actual concrete circumstances.—SCHÖNBERG *Die Volkswirthschaftslehre (Sammlung wissenschaftlicher Vorträge, Serie viii)*. (Translated for *Scientific Side-Lights.)*

1854. LAWS OF HISTORY LIKE THOSE OF SCIENCE—*Merely Statements of Cause and Effect.*—It is folly, then, to speak of the "laws of history" as of something inevitable, which science has only to discover, and whose consequences any one can then foretell, but do nothing to alter or avert. Why, the very laws of physics are conditional and deal with *ifs*. The physicist does not say, "The water will boil, anyhow"; he only says it will boil if a fire be kindled beneath it. And so the utmost the student of sociology can ever predict is that *if* a genius of a certain sort show the way, society will be sure to follow.—JAMES *Essays in Popular Philosophy*, p. 244. (L. G. & Co., 1899.)

1855. LAWS OF NATURE — *Contrasted with Laws of Man—A Deadlock Results in Public Misfortune.*—The laws of man are also laws of Nature when founded on a true perception of natural tendencies and a just appreciation of combined results. On the other hand, human laws are at variance with or antagonistic to the laws of Nature when founded either on the desire of attaining a wrong end, or on the attempt to reach a right end by mistaken means. In either of these cases positive institution and natural law become opposed, and thus a bad contrivance in legislation, like a bad contrivance in mechanics, comes always to some deadlock at last. Time and natural consequence are great teachers in politics as in other things. Our sins and our ignorances find us out. Both in conduct and in opinion natural law is ever working to convict error, to reveal and to confirm the truth.—ARGYLL *Reign of Law*, ch. 7, p. 212. (Burt.)

1856. ——— ——— *Never Subverted by Human Agency—Moral Ends Proposed in Life of Man.*—If, then, an intelligent being, after observing the order of events for an indefinite series of ages, had witnessed at last so wonderful an innovation as this [the introduction of man upon the planet], to what extent would his belief in the regularity of the system be weakened? Would he cease to assume that there was permanency in the laws of Nature? Would he no longer be guided in his speculations by the strictest rules of induction? To these questions it may be answered that had he previously presumed to dogmatize respecting the absolute uniformity of the order of Nature he would undoubtedly be checked by witnessing this new and unexpected event, and would form a more just estimate of the limited range of his own knowledge and the unbounded extent of the scheme of the universe. But he would soon perceive that no one of the fixed and constant laws of the animate or inanimate world was subverted by human agency, and that the modifications now introduced for the first time were the accompaniments of new and extraordinary circumstances, and those not of a physical but of a moral nature. The deviation permitted would also appear to be as slight as was consistent with the accomplishment of the new moral ends proposed, and to be in a great degree temporary in its nature, so that whenever the power of the new agent was withheld, even for a brief period, a relapse would take place to the ancient state of things: the domesticated animal, for example, recovering in a few generations its wild instinct, and the garden-flower and fruit-tree reverting to the likeness of the parent stock.—LYELL *Principles of Geology*, bk. i. ch. 9, p. 152. (A., 1854.)

1857. ——— ——— *Not Agents—Human Generalizations from Phenomena—Origin of Force Unknown.*—The laws of Nature are merely mental generalizations of our own, and so far as they go show a remarkable harmony between our mental nature and that manifested in the universe. They are not themselves powers capable of producing effects, but merely express what we can ascertain of uniformity of action in Nature. The law of gravitation, for example, gives no clue to the origin of that force, but merely expresses its constant mode of action in whatever way that may have been determined at first. Nor are natural laws decrees of necessity. They might have been otherwise—nay, many of them may be otherwise in parts of the uni-

verse inaccessible to us, or they may change in process of time; for the period over which our knowledge extends may be to the plans of the Creator like the lifetime of some minute insect which might imagine human arrangements of no great permanence to be of eternal duration.—DAWSON *Facts and Fancies in Modern Science,* lect. 1, p. 39. (A. B. P. S.)

1858. ——— ——— *Not Matters of Experience—Faith Demanded by Scientific Doctrines.*—The most persistent outer relations which science believes in are never matters of experience at all, but have to be disengaged from under experience by a process of elimination—that is, by ignoring conditions which are always present. The *elementary* laws of mechanics, physics, and chemistry are all of this sort. The principle of uniformity in Nature is of this sort; it has to be *sought* under and in spite of the most rebellious appearances; and our conviction of its truth is far more like a religious faith than like assent to a demonstration.—JAMES *Psychology,* vol. ii, ch. 28, p. 636. (H. H. & Co., 1899.)

1859. ——— ——— *The Methods of God—Science Does Not Reach Causes.*—In the use of this word *law,* as applied to Nature, we are often grossly misunderstood. Says a recent writer, somewhat contemptuously, "The philosopher knows no better the cause of the law of gravitation than the ignorant man." The author, in his simplicity, is unaware that laws, not causes, are the end of true philosophy. We seek to study out the method of God's doings in Nature, and enunciations of this his method or will are what is meant by the "laws of Nature." If those who look coldly on science knew better its aims, we should hear less of the infidelity of the term *law,* and find fewer infidels or rejecters of that revelation which God has spread before us.

We know that this is not the only revelation; that another tells man of his duties and responsibilities, of the celestial sympathy which surrounds him and his immortal destiny—subjects far beyond the teachings of physical or brute nature. The one is but the complement of the other; the two harmonious in their truths, as in their exalted origin.—DANA *Proceedings of the American Association for the Advancement of Science, 1855,* vol. ix, p. 1.

1860. ——— ——— *The Thoughts of God.*—Let me not be understood to imply a belief that man cannot attain to any absolute scientific truth; for I believe that he can, and I feel that every great generalization brings him a step nearer to the promised goal. Moreover, I sympathize with that beautiful idea of Oersted which he expressed in the now familiar phrase, "*The laws of Nature are the thoughts of God*"; but then I also know that our knowledge of these laws is as yet very imperfect, and that our human systems must be at the best but very partial expressions of the truth. Still, it is a fact worthy of our profound attention that in each of the physical sciences, as in astronomy, the successive great generalizations which have marked its progress have included and expanded rather than superseded those which went before them. Through the great revolutions which have taken place in the forms of thought the elements of truth in the successive systems have been preserved, while the error has been as constantly eliminated; and so, as I believe, it always will be, until the last generalization of all brings us into the presence of that law which is indeed the thought of God.—COOKE *The New Chemistry,* lect. 1, p. 2. (A., 1899.)

1861. ——— ——— *Used in Works of Nature as in Works of Man—Structure Adapted to Their Demands—Design in Structure of Barnacles.*—Now, the laws of Nature appear to be employed in the system of Nature in a manner precisely analogous to that in which we ourselves employ them. The difficulties and obstructions which are presented by one law in the way of accomplishing a given purpose are met and overcome exactly on the same principle on which they are met and overcome by man, viz., by knowledge of other laws and by resource in applying them—that is, by ingenuity in mechanical contrivance. It cannot be too much insisted on that this is a conclusion of pure science. The relation which an organic structure bears to its purpose in Nature can be recognized as certainly as the same relation between a machine and its purpose in human art. It is absurd to maintain, for example, that the purpose of the cellular arrangement of material in combining lightness with strength is a purpose legitimately cognizable by science in the Menai Bridge, but is not as legitimately cognizable when it is seen in Nature, actually serving the same use. The little barnacles which crust the rocks at low tide, and which to live there at all must be able to resist the surf, have the building of their shells constructed strictly with reference to this necessity. It is a structure all hollowed and chambered on the plan which engineers have so lately discovered as an arrangement of material by which the power of resisting strain or pressure is multiplied in an extraordinary degree. That shell is as pure a bit of mechanics as the bridge, both being structures in which the same arrangement is adapted to the same end.—ARGYLL *Reign of Law,* ch. 2, p. 59. (Burt.)

1862. LAWS, ORDINARY, SUPERSEDED—*The Preservation of the Jews—Result Yet Reached by the Use of Means.*—The preservation of the Jews as a distinct people during so many centuries of complete dispersion is a fact standing nearly, if not absolutely, alone in the history of the world. It is at variance with all other experience of the laws which govern the amalgamation

with each other of different families of the human race. . . . It is not surprising, therefore, that the preservation of the Jews, partly from the relation in which it stands to the apparent fulfilment of prophecy, and partly from the extraordinary nature of the fact itself, is tacitly assumed by many persons to come strictly within the category of miraculous events. Yet in itself it is nothing more than a striking illustration how a departure from the "ordinary course of Nature" may be effected through the instrumentality of means which are natural and comprehensible. An extraordinary resisting power has been given to the Jewish people against those dissolving and disintegrating forces which have caused the disappearance of every other race placed under similar conditions. They have been torn from home and country and removed, not in a body, but in scattered fragments over the world. Yet they are as distinct from every other people now as they were in the days of Solomon. Nevertheless this resisting power, wonderful tho it be, is the result of special laws, overruling those in ordinary operation. It has been effected by the use of means. Those means have been superhuman —they have been beyond human contrivance and arrangement. But they belong to the region of the natural. They belong to it not the less, but all the more, because in their concatenation and arrangement they seem to indicate the purpose of a living will seeking and effecting the fulfilment of its designs. This is the manner after which our own living wills in their little sphere effect their little objects. Is it difficult to believe that after the same manner also the divine will, of which ours is the image only, works and effects its purposes?—ARGYLL *Reign of Law*, ch. 1, p. 12. (Burt.)

1863. LEAD-FRONDS GROWING LIKE FERNS AROUND VOLTAIC WIRE—By sending a voltaic current through a liquid you know that we decompose the liquid, and if it contains a metal we liberate this metal by the electrolysis. . . . Into the cell [containing a solution of acetate of lead] are dipped two very thin platinum wires, and these are connected by other wires with a small voltaic battery. On sending the voltaic current through the solution the lead will be slowly severed from the atoms with which it is now combined; it will be liberated upon one of the wires, and at the moment of its liberation it will obey the polar forces of its atoms and produce crystalline forms of exquisite beauty, . . . sprouting like ferns from the wire, appearing, indeed, like vegetable growths rendered so rapid as to be plainly visible to the naked eye. On reversing the current these wonderful lead-fronds will dissolve, while from the other wire filaments of lead dart through the liquid. In a moment or two the growth of the lead-trees recommences, but they now cover the other wire.—TYNDALL *Lectures on Light*, lect. 3, p. 105. (A., 1898.)

1864. LEAF-TRACERY IN THE ANCIENT ROCKS—*Enduring Record of the Evanescent.*—The earth had already its seasons, its spring and summer, its autumn and winter, its seed-time and harvest, tho neither sower nor reaper was there; the forests then, as now, dropped their thick carpet of leaves upon the ground in the autumn, and in many localities they remain where they originally fell, with a layer of soil between the successive layers of leaves—a leafy chronology, as it were, by which we read the passage of the years which divided these deposits from each other. Where the leaves have fallen singly on a clayey soil favorable for receiving such impressions they have daguerreotyped themselves with the most wonderful accuracy, and the oaks, poplars, willows, maples, walnuts, gum- and cinnamon-trees, etc., of the Tertiaries are as well known to us as are those of our own time.—AGASSIZ *Geological Sketches*, ser. i, ch. 7, p. 182. (H. M. & Co., 1896.)

1865. LEAPS OF NATURAL PROCESSES—*The Metamorphoses of Insects.*—When we think of the mystery involved in the metamorphoses of insects and in the corresponding phenomena of alternate generation in other classes of the animal kingdom, we must see what unlimited possibilities of creation lie open in methods which are in full operation round us. In the higher animals the development of germs is carried on in vital and physical connection with the perfected organism of the mother, and the cycle of changes which lead up to the completion of the parent form is a cycle which thus appears to be wholly governed by the surrounding medium. But when we look at the metamorphoses of insects no such delusion is possible. A creature which to all appearance is fully formed, and which has led a separate and independent existence, suddenly lays itself to sleep. In that condition, without any food—without any contact with any directing physical agency external to itself—its organization is wholly altered, its whole body is rearranged, its old members dissolve and disappear, new members emerge, and in a few days or weeks are perfected in form and in power. Moreover, that form and that power are both for uses which, so far as the creature's previous "experience" is concerned, are absolutely new. With such "leaps" as this in the creative work going on in every field and stream and sea around us, we may have the utmost confidence that the same work has involved the same principles through all time.—ARGYLL *Unity of Nature*, ch. 7, p. 161. (Burt.)

1866. LEARNING, NO ROYAL ROAD TO—*Archimedes Instructing the King.*—One day the Tyrant of Syracuse ordered the illustrious Archimedes to omit the principal mathematics in a lesson on astronomy which prom-

ised well, but commenced a little severely. "Let us proceed," replied Archimedes, without modifying his professorial tone—"let us proceed: there is here no privileged road for kings." In astronomy there is no privileged road for any one, and if we wish to gain information it is indispensable that we should first understand the principles of geometrical measurements.—FLAMMARION *Popular Astronomy,* bk. ii, ch. 1, p. 85. (A.)

1867. LEARNING THE WAY NECESSARY FOR BEES—*Sense of Direction Not a Blind Instinct.*—Sir John Lubbock [Lord Avebury] observes: "I never found bees to return if brought any considerable distance at once. By taking them, however, some twenty yards each time they came to the honey I at length *trained* them to come to my room"; that is to say, bees require to *learn* their way little by little before they can return to a store of honey which they may have been fortunate enough to find; their general sense of direction is not in itself a sufficient guide. This, at least, is the case where, as in the experiments in question, the bees are *carried* from the hive to the store of honey (here a distance of less than 200 yards); possibly if they had found the honey by themselves flying towards it, and so probably taking note of objects by the way, one journey might have proved sufficient to teach them the way. But whether or not this would have been the case, the fact that when carried they required also to be taught the way piece by piece is conclusive proof that their sense of direction *alone* is not sufficient to enable them to traverse a route of 200 yards a second time.—ROMANES *Animal Intelligence,* ch. 4, p. 145. (A., 1899.)

1868. LEAVEN AN INVENTION OF WOMAN—"If there be any one discovery owing to chance it is that of leaven. The world was indebted to the economy of some person or other for this happy discovery, who, in order to save a little dough, mixed it with the new. They would, no doubt, be surprised to find that this old dough, so sour and distasteful itself, rendered the new bread so much lighter, more savory, and easy of digestion. More probably leaven arose in hot countries, in the preference shown for the acid flavor of stale porridge (compare the practise of adding curds to fresh milk in order to turn it sour for immediate consumption), as in the *caffa* or porridge-ball of Guinea, which is considered insipid while fresh."—LANDER, quoted by MASON in *Woman's Share in Primitive Culture,* ch. 2, p. 30. (A., 1894.)

1869. LEAVES ON THE MARCH—*Procession of Sauba or Leaf-cutting Ants—Relays of Workers Supplement Each Other.*—In course of time I had plenty of opportunities of seeing them [the sauba-ants] at work. They mount the tree in multitudes, the individuals being all worker-minors [the workers of smallest size]. Each one places itself on the surface of a leaf and cuts with its sharp scissor-like jaws a nearly semicircular incision on the upper side; it then takes the edge between its jaws and by a sharp jerk detaches the piece. Sometimes they let the leaf drop to the ground, where a little heap accumulates, until carried off by another relay of workers; but generally each marches off with the piece it has operated upon, and as all take the same road to their colony the path they follow becomes in a short time smooth and bare, looking like the impression of a cart-wheel through the herbage. . . . When employed on this work their processions look like a multitude of animated leaves on the march. In some places I found an accumulation of such leaves, all circular pieces, about the size of a sixpence, lying on the pathway unattended by ants, and at some distance from any colony. Such heaps are always found to be removed when the place is revisited the next day.—BATES *Naturalist on the River Amazon,* ch. 1, p. 627. (Hum., 1880.)

1870. LIFE, ABUNDANCE OF, IN GEOLOGIC TIMES—*Fossil Fishes Numerous and Diversified.*—The fossil fishes which have been found, and which I have had an opportunity of examining in certain circumscribed regions, form a very favorable basis for comparison and estimate. At Mount Vulcan, near Verona, is a celebrated quarry, not many miles in extent, from which alone have been taken over one hundred different kinds of fossil fishes. The Adriatic in its whole extent does not furnish as many different species as are found in this quarry. I have examined the fossil fishes of the neighborhood of Riga on the Baltic, and they are more numerous than the present living species of the Baltic and German Ocean. Here, then, we have direct evidence that in former periods, within similar areas, there was as great a diversity of animals as now exists.—AGASSIZ *Structure of Animal Life,* lect. 5, p. 94. (S., 1883.)

1871. ——— ——— *Fossils in Silurian Deposits—The Ancient Earth Everywhere Teemed with Life.*—Altho the early geological periods are more legible in North America, because they are exposed over such extensive tracts of land, yet they have been studied in many other parts of the globe. In Norway, in Germany, in France, in Russia, in Siberia, in Kamchatka, in parts of South America, in short, wherever the civilization of the white race has extended, Silurian deposits have been observed, and everywhere they bear the same testimony to a profuse and varied creation. The earth was teeming then with life as now, and in whatever corner of its surface the geologist finds the old strata, they hold a dead fauna as numerous as that which lives and moves above it. Nor do we find that there was any gradual increase or decrease of any organic

forms at the beginning and close of the successive periods. On the contrary, the opening scenes of every chapter in the world's history have been crowded with life, and its last leaves as full and varied as its first.—AGASSIZ *Geological Sketches*, ser. i, ch. 2, p. 60. (H. M. & Co., 1896.)

1872. LIFE, ADVANCED, FRUITFULNESS OF—*Haydn's Success at Sixty—Diligence Rivaling Genius.*—Comfortably settled in the palace of Eisenstadt, in Hungary [as Maestro di Capella to Prince Esterhazy], enjoying in moderation his favorite diversions of hunting and fishing, and relieved from care for the future, Haydn there composed the long series of works in various styles which he produced before his visit to London at nearly sixty years of age; which visit was the immediate occasion of his bringing out his "Twelve Grand Symphonies," and indirectly (by the impression which his hearing of Handel's music made upon him) prompted the composition of the "Creation," which he produced in his sixty-fifth year. During the whole period of his residence with Prince Esterhazy, he may be said to have been educating himself, under peculiar advantages, for those great works of his advanced life on which his reputation now chiefly rests. He had a full and choice band living under the same roof with him, at his command every hour in the day; he had only to order, and they were ready to try the effect of any piece, or even of any passage which, quietly seated in his study, he might commit to paper. Thus at leisure he heard, corrected, and refined whatever he conceived, and never sent forth his compositions until they were in a state to fearlessly challenge criticism.

There can be no question of Haydn's inferiority to Mozart in creative power; but the steadiness of his application to his art, and the advantage he possessed in being constantly able to test his productions by actual trial, enabled him ultimately to attain a place among the first of modern musicians, which Mozart had reached at a bound.—CARPENTER *Mental Physiology*, ch. 6, p. 277. (A., 1900.)

1873. LIFE AND DEATH DEPEND ON NUMBER OF ATOMS—*Elements of Theine and Strychnin Identical.*—The same elements combined in one proportion are sometimes a nutritious food or a grateful stimulant, soothing and sustaining the powers of life; whilst, combined in another proportion, they may be a deadly poison, paralyzing the heart and carrying agony along every nerve and fiber of the animal frame. This is no mere theoretical possibility. It is actually the relation, for example, in which two well-known substances stand to each other—tea and strychnin. The active principles of these two substances, "theine" and "strychnin," are identical so far as their elements are concerned, and differ from each other only in the proportions in which they are combined. Such is the power of numbers in the laboratory of Nature! What havoc in this world, so full of life, would be made by blind chance gambling with such powers as these! What confusion, unless they were governed by laws whose certainty makes them capable of fine adjustment, and therefore subject to accurate control!—ARGYLL *Reign of Law*, ch. 2, p. 57. (Burt.)

1874. LIFE AND DEATH OF PLANTS DEPENDENT ON THEIR "SLEEP"—*Complicated Movements to Avoid Radiation—How the Object Is Secured.*—From the several cases above given [in the record of experiments where leaves were prevented from turning, and died in consequence], there can be no doubt that the position of the leaves at night affects their temperature through radiation to such a degree that when exposed to a clear sky during a frost, it is a question of life and death. We may therefore admit as highly probable, seeing that their nocturnal position is so well adapted to lessen radiation, that the object gained by their often complicated sleep movements, is to lessen the degree to which they are chilled at night. It should be kept in mind that it is especially the upper surface which is thus protected, as it is never directed towards the zenith, and is often brought into close contact with the upper surface of an opposite leaf or leaflet.—DARWIN *Power of Movement in Plants*, ch. 6, p. 297. (A., 1900.)

1875. LIFE A WARFARE—*Body and Mind Must Contend or Be Crushed—Trials Strengthen the Strong, Destroy the Weak.*—Life is surrounded by forces that are always tending to destroy it, and with which it may be represented as in a continued warfare: so long as it contends successfully with them, winning from them and constraining them to further its development, it flourishes; but when it can no longer strive, when they succeed in winning from it and increasing at its expense, it begins to decay and die. So it is with mind in the circumstances of its existence: the individual who cannot use circumstances, or accommodate himself successfully to them, and in the one way or the other make them further his development, is controlled and used by them: being weak, he must be miserable, must be a victim; and one way in which his suffering and failure will be manifest will be in insanity. Thus it is that mental trials which serve in the end to strengthen a strong nature break down a weak one which cannot fitly react, and that the efficiency of a moral cause of insanity betrays a conspiracy from within with the unfavorable outward circumstances.—MAUDSLEY *Body and Mind*, lect. 3, p. 93. (A., 1898.)

1876. LIFE COMPARED TO THE COMMANDER OF AN ARMY—*An Unseen Controlling Influence—Power in Skilled Conformity to Nature's Laws.*—Let us . . . suppose that a war is being carried

on by a vast army, at the head of which there is a very great commander. Now, this commander knows too well to expose his person; in truth, he is never seen by any of his subordinates. He remains at work in a well-guarded room, from which telegraphic wires lead to the headquarters of the various divisions. He can thus, by means of these wires, transmit his orders to the generals of these divisions, and by the same means receive back information as to the condition of each. Thus his headquarters becomes a center into which all information is poured, and out of which all commands are issued. Now, that mysterious thing called life, about the nature of which we know so little, is probably not unlike such a commander. Life is not a bully, who swaggers out into the open universe, upsetting the laws of energy in all directions, but rather a consummate strategist, who, sitting in his secret chamber, before his wires, directs the movements of a great army.—STEWART *Conservation of Energy*, ch. 6, p. 412. (Hum.. 1880.)

1877. LIFE DIFFUSED THROUGHOUT THE ATMOSPHERE—If the unassisted eye shows that life is diffused throughout the whole atmosphere, the microscope reveals yet greater wonders. Wheel-animalcules, *brachioni*, and a host of microscopic insects are lifted by the winds from the evaporating waters below. Motionless and to all appearance dead, they float on the breeze, until the dew bears them back to the nourishing earth. . . . The yellow meteoric sand or mist (dust nebulæ) often observed to fall on the Atlantic near the Cape Verde Islands, and not infrequently borne in an easterly direction as far as Northern Africa, Italy, and Central Europe, consists, according to Ehrenberg's brilliant discovery of agglomerations of silicious-shelled microscopic organisms. . . . Together with these developed creatures, the atmosphere contains countless germs of future formations; eggs of insects, and seeds of plants, which, by means of hairy or feathery crowns, are borne forward on their long autumnal journey. Even the vivifying pollen scattered abroad by the male blossoms is carried by winds and winged insects over sea and land, to the distant and solitary female plant. Thus, wheresoever the naturalist turns his eye, life or the germ of life lies spread before him.—HUMBOLDT *Views of Nature*, p. 211. (Bell, 1896.)

1878. LIFE, ESTIMATED DURATION OF—*Long or Short, According to Succession of Events—Sense of Duration Relative.*—We have every reason to think that creatures may possibly differ enormously in the amounts of duration which they intuitively feel, and in the fineness of the events that may fill it. Von Baer has indulged in some interesting computations of the effect of such differences in changing the aspect of Nature. Suppose we were able, within the length of a second, to note 10,000 events distinctly, instead of barely 10, as now; if our life were then destined to hold the same number of impressions, it might be 1,000 times as short. We should live less than a month, and personally know nothing of the change of seasons. If born in winter, we should believe in summer as we now believe in the heats of the Carboniferous era. The motions of organic beings would be so slow to our senses as to be inferred, not seen. The sun would stand still in the sky, the moon be almost free from change, and so on. But now reverse the hypothesis and suppose a being to get only one 1,000th part of the sensations that we get in a given time, and consequently to live 1,000 times as long. Winters and summers will be to him like quarters of an hour. Mushrooms and the swifter-growing plants will shoot into being so rapidly as to appear instantaneous creations; annual shrubs will rise and fall from the earth like restlessly boiling water-springs; the motions of animals will be as invisible as are to us the movements of bullets and cannon-balls; the sun will scour through the sky like a meteor, leaving a fiery trail behind him.—JAMES *Psychology*, vol. i, ch. 15, p. 639. (H. H. & Co., 1899.)

1879. LIFE, ETERNAL—*Scientific and Christian Definitions of, Compared.*—The exact terms of Mr. Herbert Spencer's definition of eternal life may now be given. And it will be seen that they include essentially the conditions here laid down. "Perfect correspondence would be perfect life. Were there no changes in the environment but such as the organism had adapted changes to meet, and were it never to fail in the efficiency with which it met them, there would be eternal existence and eternal knowledge." Reserving the question as to the possible fulfilment of these conditions, let us turn for a moment to the definition of eternal life laid down by Christ. Let us place it alongside the definition of science, and mark the points of contact. Uninterrupted correspondence with a perfect environment is eternal life according to science. "This is life eternal," said Christ, "that they may know thee, the only true God, and Jesus Christ whom thou has sent." Life eternal is to know God. To know God is to "correspond" with God. To correspond with God is to correspond with a perfect environment. And the organism which attains to this, in the nature of things must live forever. Here is "eternal existence and eternal knowledge."—DRUMMOND *Natural Law in the Spiritual World*, essay 6, p. 193. (H. Al.)

1880. LIFE EVIDENCED BY CHANGE—*Actions of Living Things Tend to Self-preservation.*—We habitually distinguish between a live object and a dead one by observing whether a change which we make in the surrounding conditions, or one which Nature makes in them, is or is not

followed by some perceptible change in the object. By discovering that certain things shrink when touched, or fly away when approached, or start when a noise is made, the child first roughly discriminates between the living and the not-living. . . . Vegetal and animal life are alike primarily recognized by this process. The tree that puts out leaves when the spring brings increase of temperature, the flower which opens and closes with the rising and setting of the sun, the plant that droops when the soil is dry and reerects itself when watered, are considered alive because of these induced changes. . . .

Not only, however, do we look for some response when an external stimulus is applied to a living organism, but we expect a fitness in the response. Dead as well as living things display changes under certain changes of condition: instance, a lump of carbonate of soda that effervesces when dropped into sulfuric acid; a cord that contracts when wetted; a piece of bread that turns brown when held near the fire. But in these cases we do not see a connection between the changes undergone and the preservation of the things that undergo them. . . . In vital changes, however, such relations are manifest. Light being necessary to vegetal life, we see in the action of a plant which, when much shaded, grows towards the unshaded side, an appropriateness which we should not see did it grow otherwise. Evidently the proceedings of a spider which rushes out when its web is gently shaken and stays within when the shaking is violent, conduce better to the obtainment of food and the avoidance of danger than were they reversed. The fact that we feel surprise when, as in the case of a bird fascinated by a snake, the conduct tends towards self-destruction, at once shows how generally we have observed an adaptation of living changes to changes in surrounding circumstances.—SPENCER *Biology*, pt. i, ch. 5, p. 91. (A., 1900.)

1881. LIFE, EXPERIMENTS FOR RESTORATION OF—Have I the right to conclude from these tests that the injection of blood deprived of its fibrin could suffice to support irritability indefinitely and perfectly, that is to say, the local life of a member separated from the body? At the least, this seems very probable, for, I repeat it, there never was any sensible difference in the degree of muscular irritability fifty and some hours from ten minutes after death.—BROWN-SÉQUARD *Recherches experimentales sur les Propriétés physiologiques et les Usages du Sang Rouge et du Sang Noir (Journal de la Physiologie de l'Homme et des Animaux, 1858*, vol. i, p. 367). (Translated for *Scientific Side-Lights.*)

1882. LIFE, FECUNDITY OF LOWER FORMS OF—*Progeny Numberless—Gradual Diminution in Rising toward Higher Mammalia—Care and Love Concentrated.*—When we examine the progeny of the lowest plants we find ourselves among figures so high that no microscope can count them. The *Protococcus nivalis* shows its exuberant reproductive power by reddening the arctic landscape with its offspring in a single night. When we break or shake the puff-ball of the well-known fungus the cloud of progeny darkens the air with a smoke made up of uncountable millions of spores. *Hydatina senta*, one of the *Rotifera*, propagates four times in thirty-four hours, and in twelve days is the parent of sixteen million young. Among fish the number is still very great. The herring and the cod give birth to a million ova, the frog spawns eggs by the thousand, and most of the creatures at and below that level in a like degree. Then comes a gradual change. When we pass on to the reptiles the figures fall into hundreds. On reaching the birds the young are to be counted by tens or units. In the highest of mammals the rule is one. This bringing-down of the numbers is a remarkable circumstance. It means the calling-in of a diffused care, to focus it upon one, and concentrate it into love.—DRUMMOND *Ascent of Man*, ch. 8, p. 273. (J. P., 1900.)

1883. LIFE FIGHTS OFF CORRUPTION—*Bacteria Cannot Thrive on Normal Living Tissues.*—The normal living tissues have an inimical effect upon bacteria. Saprophytic bacteria of various kinds are normally present on exposed surfaces of skin or mucous membrane. Tissues also which are dead or depressed in vitality from injury or previous disease, but which are still in contact with the tissues, afford an excellent nidus for the growth of bacteria. Still these have not the power, unless specific, to thrive in the normal living tissue. It has been definitely shown that the blood-fluids of the body have in their fresh state the germicidal power . . . which prevents bacteria from flourishing in them.—NEWMAN *Bacteria*, ch. 8, p. 267. (G. P. P., 1899.)

1884. LIFE, FORCES OF, DESTROY USELESS ORGANS—*White Cells (Leucocytes) Devour Tadpole's Tail and Gills.*—When the young frog or tadpole attains a certain stage of development, and when it is about to exchange its water-life for the higher land existence, the fishlike tail requires repression and demands extinction as part and parcel of frog-advance. Of old we believed the disappearance of the frog's tail was due to a simple process of atrophy or wasting away. We know better to-day. By close microscopic investigation we are able to see a curious work proceeding in the tadpole's appendage. It swarms with white cells which have migrated into its substance from the blood-vessels. They are there for a purpose, and they work with a will. They are seen in the act of eating and devouring the substance of their possessor. The tadpole in this sense, and through its semi-independent white-blood cells, is living upon

itself, and eating up life's "principal" in place of living upon the interest represented by its food. Within the bodies of these white cells in the tadpole's tail microscopists have been enabled actually to see the fragments of muscle and nerve they have torn from the tail substance. Little wonder that the tail "grows small by degrees and beautifully less" under such a vigorous attack; and in the gills of the tadpole (which disappear with the tail) the same devouring process is seen to proceed. Thus the disappearance of the tail is a matter of vital action—as much so, indeed, in one sense, as its growth. It is a new experience of life to find certain of the living particles of the body set apart, as in the case of the frog, for the work of ridding that body of its encumbrance, and of assisting it to rise in the scale of life.—WILSON *Glimpses of Nature*, ch. 23, p. 76. (Hum., 1892.)

1885. LIFE FOR OTHERS—*A Natural Law.*—They who perceive that all the nature of living things is primarily for the good of others . . . can no longer wonder if something in our own nature should impel us to acts which are not to our personal liking or advantage; nor need they fear lest the discovery of the natural history of the moral sense may destroy its value. Should it not rather "seem to follow that reasonable creatures were, as the philosophical emperor observes, made one for another; and consequently that man ought not to consider himself as an independent individual, whose happiness is not connected with that of other men; but rather as a part of a whole, to the common good of which he ought to conspire, and order his ways and actions suitably, if he would live according to nature"? [Berkeley, "Alciphron," i, 16].—BROOKS *Foundations of Zoology*, lect. 5, p. 119.

1886. LIFE, FUTURE POSSIBILITIES INVOLVED IN—*Difference between Crystal and Shell.*—The difference on the score of beauty between the crystal and the shell, let us say once more, is imperceptible. But fix attention for a moment, not upon their appearance, but upon their possibilities, upon their relation to the future, and upon their place in evolution. The crystal has reached its ultimate stage of development. It can never be more beautiful than it is now. Take it to pieces and give it the opportunity to beautify itself afresh, and it will just do the same thing over again. It will form itself into a six-sided pyramid, and go on repeating this same form *ad infinitum* as often as it is dissolved, and without ever improving by a hair's breadth. Its law of crystallization allows it to reach this limit, and nothing else within its kingdom can do any more for it. In dealing with the crystal, in short, we are dealing with the maximum beauty of the inorganic world. But in dealing with the shell we are not dealing with the maximum achievement of the organic world. In itself it is one of the humblest forms of the invertebrate sub-kingdom of the organic world; and there are other forms within this kingdom so different from the shell in a hundred respects that to mistake them would simply be impossible.—DRUMMOND *Natural Law in the Spiritual World*, essay 11, p. 345. (H. Al.)

1887. LIFE, HIGHER, MENACED BY LOWER—*Garden Plants Destroyed by Bacteria.*—Reference has been made to the associated work of higher vegetable life and bacteria. The converse is also true. Just as we have bacterial diseases affecting man and animals, so also plant-life has its bacterial diseases. . . . Hyacinth disease is due to a flagellated bacillus. The wilt of cucumbers and pumpkins is a common disease in some districts of the world, and may cause wide-spread injury. It is caused by a white microbe which fills the water-ducts. Wilting vines are full of the same sticky germs. Desiccation and sunlight have a strongly prejudicial effect upon these organisms. Bacterial brown-rot of potatoes and tomatoes is another plant-disease probably due to a bacillus. The bacillus passes down the interior of the stem into the tubers, and brown-rots them from within. There is another form of brown-rot which affects cabbages. It blackens the veins of the leaves, and a woody ring which is formed in the stem causes the leaves to fall off. This also is due to a micro-organism which gains entrance through the water-pores of the leaf, and subsequently passes into the vessels of the plants.—NEWMAN *Bacteria*, ch. 1, p. 35. (G. P. P., 1899.)

1888. LIFE, HUMAN, WHOLESALE DESTRUCTION OF—*Earthquake Followed by Pestilence.*—In this [Calabrian] earthquake 40,000 persons are supposed to have perished, and about 20,000 by the epidemics which followed. Dolomieu gives a painful account of the appearance of the Calabrian cities. "When I passed over to Calabria," he writes, "and first beheld Polistina, the scene of horror almost deprived me of my faculties; my mind was filled with mingled horror and compassion; nothing had escaped; all was leveled with the dust; not a single house or piece of wall remained; on all sides were heaps of stone so destitute of form that they afforded no idea of there having ever been a town on this spot. The stench of the dead bodies still arose from the ruins. I conversed with many persons who had been buried for three, four, or even five days; I questioned them respecting their sensations in so dreadful a situation, and they agreed that of all the physical evils they endured thirst was the most intolerable; and that their mental agony was increased by the idea that they were abandoned by their friends, who might have rendered them assistance."—PROCTOR *Notes on Earthquakes*, p. 4. (Hum., 1887.)

1889. LIFE, INDIVIDUAL—*Fitting into Broad Scheme of Nature—Bee Seeking Honey Fertilizes Flowers for Future Generations.*—At Torquay I watched for about half an hour a number of these flowers (*Spiranthes*) growing together, and saw three humblebees of two kinds visit them. I caught one and examined its proboscis: on the superior lamina, some little way from the tip, two perfect pollinia were attached, and three other boat-formed disks without pollen; so that this bee had removed the pollinia from five flowers, and had probably left the pollen of three on the stigmas of other flowers. The next day I watched the same flowers for a quarter of an hour, and caught another humblebee at work; one perfect pollinium and four boat-formed disks adhered to its proboscis, one on the top of the other, showing how exactly the same part of the rostellum had each time been touched.

The bees always alighted at the bottom of the spike, and, crawling spirally up it, sucked one flower after the other. I believe humblebees generally act in this manner when visiting a dense spike of flowers, as it is the most convenient method; on the same principle that a woodpecker always climbs up a tree in search of insects. . . . The bee goes first to the lowest flower, and, crawling spirally up the spike, effects nothing on the first spike which she visits till she reaches the upper flowers, and then she withdraws the pollinia. She soon flies to another plant, and, alighting on the lowest and oldest flower, into which a wide passage will have been formed from the greater reflection of the column, the pollinia strike the protuberant stigma. If the stigma of the lowest flower has already been fully fertilized, little or no pollen will be left on its dried surface; but on the next succeeding flower, of which the stigma is adhesive, large sheets of pollen will be left. Then as soon as the bee arrives near the summit of the spike she will withdraw fresh pollinia, will fly to the lower flowers on another plant, and fertilize them: and thus, as she goes her rounds and adds to her store of honey, she continually fertilizes fresh flowers and perpetuates the race of our autumnal *Spiranthes*, which will yield honey to future generations of bees.—DARWIN *Fertilization of Orchids*, ch. 4, p. 113. (A., 1898.)

1890. ——— ——— *Within Life of Organization—Leucocytes and Ciliated Cells in the Body.*—The individual lives of the units [cells] are subordinate to the general life in proportion as this is high. . . . Even in the highest types, however, and even when they are fully developed, unit life does not wholly disappear: it is clearly shown in ourselves. . . . [In the blood] the white corpuscles or leucocytes, retaining the primitive and ameboid character, exhibit individual activities: send out prolongations like pseudopodia, take in organic particles as food, and are independently locomotive. Tho far less numerous than the red corpuscles, yet, as ten thousand are contained in a cubic millimeter of blood—a mass less than a pin's head—it results that the human body is pervaded throughout all its blood-vessels by billions of these separately living units. In the lymph, too, . . . these ameboid units are found. Then we have the curious transitional stage in which units partially embedded and partially free display a partial unit life. These are the ciliated epithelium-cells, lining the air-passages. . . . The inner parts of these unite with their fellows to form an epithelium, and the outer parts of them, immersed either in liquid or semi-liquid (mucus), bear cilia that are in constant motion and "produce a current of fluid over the surface they cover," thus simulating in their positions and actions the cells lining the passages ramifying through a sponge. The partially independent lives of these units is further seen in the fact that after being detached they swim about in water for a time by the aid of their cilia.—SPENCER *Biology*, pt. ii, ch. 2A, p. 186. (A., 1900.)

1891. LIFE, INFINITE AND ETERNAL—*Light Transports Us into.*—The rays of light which fall in silence from the distant splendors of the starry night bring to us, then, the most curious revelations on the state of creation in these inaccessible universes, and prove to us that the substances and forces which we see in activity around us exist there as well as here, producing effects analogous to those which surround our field of view, developing the sphere of our conceptions at the same time as that of our observations, and permitting us to divine the things, the beings, the populations, the unknown works which reproduce in infinitude the spectacles of life, the sports of Nature, and the varied operations of which our solar system presents but an ordinary and incomplete scene. Light transports us into the *infinite life*. It transports us also into the *eternal life*.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 616. (A.)

1892. LIFE IN INCESSANT PERIL—*Provision against Earthquakes—"Earthquake Lamps"—"Earthquake Coats."*—The great danger of fire [as the result of earthquake] may partially be obviated by the use of "earthquake lamps," which are so constructed that before they overturn they are extinguished. It is said that in South America some of the inhabitants are ready at any moment to seek refuge in the streets, and they have coats prepared, stocked with provisions and other necessaries, which, if occasion demands, will enable them to spend the night in the open air. These coats [are] called "earthquake coats."—MILNE *Earthquakes*, ch. 7, p. 129. (A., 1899.)

1893 LIFE IN INFUSIONS—*Errors of Experiment—Lifelessness Presumes Correct Manipulation.*—As regards workmanship, moreover, he [the investigator] will not fail to bear in mind that fruitfulness may be due to errors of manipulation, while barrenness involves the presumption of correct experiment. It is only the careful worker that can secure the latter, while it is open to every novice to obtain the former. Barrenness is the result at which the conscientious experimenter, whatever his theoretic convictions may be, ought to aim, omitting no pains to secure it, and resorting only when there is no escape from it to the conclusion that the life observed comes from no source which correct experiment could neutralize or avoid.—TYNDALL *Fragments of Science*, vol. ii, ch. 13, p. 318. (A., 1900.)

1894. LIFE IN OCEAN DEPTHS—*A Few Fossil Forms Still Living—Most Forms Modern Modified.*—Besides proving the existence of a fauna in the sea at all depths and in all regions, the expedition [of the "Challenger," 1873] further proved that the abysmal fauna, taken as a whole, does not possess characters similar to those of the fauna of any of the Secondary or even Tertiary rocks. A few forms, it is true, known to us up to that time only as fossils, were found to be still living in the great depths, but a large majority of the animals of these regions were found to be new and specially modified forms of the families and genera inhabiting shallow waters of modern times. No trilobites, no blastoids, no cystoids, no new ganoids, and scarcely any deep-sea elasmobranchs were brought to light, but the fauna was found to consist mainly of teleosteans, crustacea, cœlentera, and other creatures unlike anything known to have existed in Paleozoic times, specially modified in structure for their life in the great depths of the ocean.—HICKSON *Fauna of the Deep Sea*, ch. 1, p. 14. (A., 1894.)

1895. ——— ——— *How the Mighty Pressure Is Borne—Glass Crushed to Powder.*—In regard to the animal life of the deep sea, the "Challenger" researches do not seem likely to yield any new general result of striking interest. Our previous work had shown that a depth of three miles, a pressure of three tons on the square inch, an entire absence of sunlight, and a temperature below 32° might be sustained by a considerable number and variety of animal types, and this conclusion has been fully confirmed and widely extended. Many specimens have been brought up alive from depths exceeding four miles, at which the pressure was four tons on the square inch, considerably exceeding that exerted by the hydraulic presses used for packing Manchester goods. Even the "protected" thermometers specially constructed for deep-sea sounding were frequently crushed; and a sealed glass tube containing air, having been lowered (within a copper case) to a depth of 2,000 fathoms, was reduced to a fine powder almost like snow by what Sir Wyville Thomson ingeniously characterized as an *im*plosion, the pressure having apparently been resisted until it could no longer be borne, and the whole having been then disintegrated at the same moment. The rationale of the resistance afforded by soft-bodied animals to a pressure which thus affects hard glass is simply that they contain no air, but consist of solids and liquids only; and that since their constituent parts are not subject to more than a very trifling change of bulk, while the equality of the pressure in every direction will prevent any change in their form, there is really nothing to interfere with the ordinary performance of their vital functions.—CARPENTER *Nature and Man*, lect. 11, p. 344. (A., 1889.)

1896. LIFE IN UNEXPECTED PLACES—*Worms that Live in Brine—Every Part of the World Habitable—Why Not Life in Other Worlds?*—The mud in many places [about the salt lakes] was thrown up by numbers of some kind of worm, or annelidous animal. How surprising it is that any creatures should be able to exist in brine, and that they should be crawling among crystals of sulfate of soda and lime! And what becomes of these worms when during the long summer the surface is hardened into a solid layer of salt? Flamingoes in considerable numbers inhabit this lake and breed here; throughout Patagonia, in northern Chile, and at the Galapagos Islands I met with these birds wherever there were lakes of brine. I saw them here wading about in search of food—probably for the worms which burrow in the mud; and these latter probably feed on infusoria or confervæ. Thus we have a little living world within itself, adapted to these inland lakes of brine. . . .

Well may we affirm that every part of the world is habitable! Whether lakes of brine, or those subterranean ones hidden beneath volcanic mountains—warm mineral springs—the wide expanse and depths of the ocean—the upper regions of the atmosphere, and even the surface of perpetual snow—all support organic beings.—DARWIN *Naturalist's Voyage around the World*, ch. 4, p. 66. (A., 1898.)

1897. LIFE, ITS TRANSFORMING POWER—*Exchange of Functions among Vital Organs.*—The roots and leaves of plants are widely differentiated in their functions: by the roots, water and mineral substances are absorbed, while the leaves take in and decompose carbonic acid. Nevertheless, some leaves can absorb water, and in what are popularly called "air-plants" the absorption of water is mainly carried on by them and by the stems. Conversely, the underground parts can partially assume the functions of leaves. The exposed tuber of a potato develops chlorophyl on its surface, and in other cases, as in that of the turnip, roots, properly so called, do the like. In

trees the trunks, which have in great measure ceased to produce buds, recommence producing them if the branches are cut off; sometimes aerial branches send down roots to the earth, and under some circumstances the roots, tho not in the habit of developing leaf-bearing organs, send up numerous suckers. When the excretion of bile is arrested, part goes to the skin and some to the kidneys, which presently suffer under their new task. . . . The excretion of carbonic acid and absorption of oxygen are mainly performed by the lungs, in creatures which have lungs; but in such creatures there continues a certain amount of cutaneous respiration, and in soft-skinned batrachians like the frog this cutaneous respiration is important.—SPENCER *Biology*, pt. ii, ch. 3, p. 208. (A., 1900.)

1898. LIFE, MICROSCOPIC, IN THE ALPINE LAKES — *Organisms Invisible by Transparency.*—Perhaps few of the many thousands of people who annually rock upon the blue lakes among the Alps, feeling perfectly at home, ever dream that in this crystal flood there also float myriads of active animals. But the very monotony of the conditions of life there corresponds to the composition of the pelagic fauna. Besides wheel-animalculæ, representatives of the smallest life *(Infusoria flagellata)* are frolicking among the countless numbers of microscopic algæ; and a few varieties of tiny crabs from a few millimeters to two centimeters in length also inhabit these high lakes in tremendous numbers. They are queer fellows with immense paddle arms and long projections of the body that serve as balancing poles, for they are condemned for life to swim without ever resting in their fluid element, whose specific gravity is of course only a little greater than that of their bodies. Any one confronted for the first time with these animalculæ in a glass of water would seek in vain for them, even if there were hundreds, as it is only after the most minute observation that the dark pigment of the eyes or the faintest coloring of the contents of the intestines will betray their presence. The transparency of the bodily substance of the pelagic sea animals has long been known. Here, as there, this adaptation to the constitution of the water is a means of protecting the delicate creatures from extermination, because it withdraws them from the view of their pursuer. Since, from the tenderness of their bodies, they would not be able to endure the beating of the waves, the minutest crinkling of the water's surface, the gentlest breath of wind, will drive them into depths where the movements on the surface of the water are no longer experienced.—GRAFF *Die Fauna der Alpenseen*, p. 12. (Translated for *Scientific Side-Lights.)*

1899. LIFE MOLDS ENVIRONMENT —*Beavers Changing Surface of Continent.*—Beaver-dams afford still another illustration of the manner in which drainage is obstructed and lakes formed by organic agencies. Beavers formerly lived over nearly the whole of North America, and are still found in limited numbers in the Northern States and Canada, and extending southward along the Cordilleras at least as far as New Mexico. The dams they constructed with great intelligence and skill, across small streams, retained drift logs and floating leaves, thus leading to the accumulation of deposits which obstructed the drainage for a long time after they had been abandoned by the animals that built them. The ponds and swamps due to the work of beavers number tens of thousands, and have produced important changes in the minor features of the surface of the continent. Many of these ponds, after becoming choked with vegetation and converted into peat swamps, have been drained and furnish rich garden-lands.—RUSSELL *Lakes of North America*, ch. 1, p. 27. (G. & Co., 1895.)

1900. LIFE, NATURAL, DEFINED—*The Sum Total of the Functions that Resist Death—Life, Spiritual, the Sum Total of the Functions that Resist Sin.*—This law, which is true for the whole plant-world, is also valid for the animal and for man. Air is not life, but corruption—so literally corruption that the only way to keep out corruption, when life has ebbed, is to keep out air. Life is merely a temporary suspension of these destructive powers; and this is truly one of the most accurate definitions of life we have yet received—"the sum total of the functions which resist death."

Spiritual life, in like manner, is the sum total of the functions which resist sin. The soul's atmosphere is the daily trial, circumstance, and temptation of the world. And as it is life alone which gives the plant power to utilize the elements, and as, without it, they utilize it, so it is the spiritual life alone which gives the soul power to utilize temptation and trial; and without it they destroy the soul.—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 93. (H. Al.)

1901. LIFE, NATURE OF, UNKNOWN TO SCIENCE—Science has cast no light on the ultimate nature of life. But whatever it be, it has evidently fundamental elements which are the same throughout the whole circle of the organic world.—ARGYLL *Unity of Nature*, ch. 2, p. 29. (Burt.)

1902. LIFE, NONE, WITHOUT ANTECEDENT LIFE—*Refutation of the Theory of Spontaneous Generation.*—Standing on the Mer de Glace, near the Montanvert, he [Pasteur] snipped off the ends of a number of hermetically sealed flasks containing organic infusions. One out of twenty of the flasks thus supplied with glacier air showed signs of life afterwards, while eight out of twenty of the same infusions, supplied with the air of the plains, became crowded with

life. He took his flasks into the caves under the Observatory of Paris, and found the still air in these caves devoid of generative power. These and other experiments, carried out with a severity perfectly obvious to the instructed scientific reader, and accompanied by a logic equally severe, restored the conviction that, even in these lower reaches of the scale of being, life does not appear without the operation of antecedent life.—TYNDALL *Floating Matter of the Air,* essay 5, p. 285. (A., 1895.)

1903. LIFE NOT IN MATERIAL ELEMENTS—*The Water Is Left, the Wave Goes On—Spirit Not Revealed to Sense.*—Just as the flame remains the same in appearance, and continues to exist with the same form and structure, altho it draws every minute fresh combustible vapor, and fresh oxygen from the air, into the vortex of its ascending current; and just as the wave goes on in unaltered form, and is yet being reconstructed every moment from fresh particles of water, so also in the living being, it is not the definite mass of substance, which now constitutes the body, to which the continuance of the individual is attached. For the material of the body, like that of the flame, is subject to continuous and comparatively rapid change—a change the more rapid, the livelier the activity of the organs in question. Some constituents are renewed from day to day, some from month to month, and others only after years. That which continues to exist as a particular individual is like the flame and the wave—only the form of motion which continually attracts fresh matter into its vortex and expels the old. The observer with a deaf ear only recognizes the vibration of sound as long as it is visible and can be felt, bound up with heavy matter. Are our senses, in reference to life, like the deaf ear in this respect?—HELMHOLTZ *Popular Lectures,* lect. 4, p. 195. (L. G. & Co., 1898.)

1904. LIFE OF WANDERING GERMS—*Unseen Perils—Long-enduring Menace of Evil Once Set Afloat—The Source of Life Infected.*—So essentially does the bacterial content of air depend upon the facility with which certain bacteria withstand drying that Dr. Eduardo Germano has addressed himself first to drying various pathogenic species and then to mixing the dried residue with sterilized dust and observing to what degree the air becomes infected. Typhoid appears to withstand comparatively little desiccation without losing its virulence. Nevertheless, it is able to retain vitality in a semidried condition, and it is owing to this circumstance in all probability that it possesses such power of infection. Diphtheria [is], on the other hand, capable of lengthened survival outside the body. . . . This is not the case with cholera or plague. Dr. Germano classifies bacteria, as a result of his researches, into three groups: first, those like plague, typhoid, and cholera, which cannot survive drying for more than a few hours; second, those like the bacilli of diphtheria, . . . which can withstand it for a longer period; thirdly, those like tubercle, which can very readily resist drying for months and yet retain their virulence. . . . Miquel has recently demonstrated that soil bacteria or their spores can remain alive in hermetically sealed tubes for as long a time as sixteen years. Even at the end of that period the soil inoculated into a guinea-pig produced tetanus.—NEWMAN *Bacteria,* ch. 3, p. 108. (G. P. P., 1899.)

1905. LIFE ON THE MOONS OF JUPITER—*Glorious Aspect of Jupiter as Seen from His Satellites—The Giant Planet a Minor Sun.*—Why should not the moons of Jupiter be inhabited, instead of Jupiter himself, and Jupiter be appointed to compensate them (not they him) for the smallness of the direct supply of solar light and heat? . . . For to them the sun is a minute body, showing a disk scarcely equal to one twenty-fifth of the sun's disk as we see him; but the glorious disk of Jupiter, varying at the several moons from an area 1,600 times as great as their sun to an area 35,000 times his, and marked by the wonderfully beautiful colors of which our telescopes afford a faint idea, must be an amazing object of contemplation. The changes also which take place in his aspect as he turns round on his axis, and also as real changes take place in his cloud envelope, must be singularly impressive and suggestive. We may well believe that if there are reasoning creatures on the worlds which circle around Jupiter, they have as good reason as we ourselves to say, "The heavens declare the glory of God, the firmament showeth his handiwork."—PROCTOR *Expanse of Heaven,* pp. 88-93. (L. G. & Co., 1897.)

1906. LIFE, PHYSICAL, COOPERATION IN—*The Human Body a Colony of Cell-workers—Division Resulting in Harmony.*—If we think of the countless operations which have to be undertaken from hour to hour to maintain our bodies in action, we may begin to realize what perfect cooperation really means, and what this colonial constitution of ours implies. For example, saliva has to be secreted, for the purpose of digestion, in the mouth, and for other functions as well. This fluid is supplied by three pairs of salivary glands. Now, the working and essential parts of these glands are living cells, which, out of the blood (as the raw material) supplied to the glands, secrete saliva, which is the manufactured product. Again, tears have perpetually to be made for washing the eyes. This secretion is supplied by a couple of tear glands. Here, again, are cells, different from those of the salivary glands, and making out of the blood a very different secretion to that of the mouth. The cells of the gastric glands of the stomach make, from the blood, gastric juice. . . . The brain-cells guide

and direct the body's highest acts equally with lower nervous operations. Cells in the skin repair our wounds and throw off other cells which are cast away as the outer skin wears. The bone-cells renew and repair that dense structure, and build up the solid portions of the frame. In a word, every act of life is performed by the cells, each group of which remains distinct as a colony of workers charged with the performance of a specific duty. Truly, then, it may be held that our life is a divided existence physically; while from another point of view it is an harmonious existence, because of the perfect cooperation of these wonderful workers of the body—the living cells.—ANDREW WILSON *Glimpses of Nature,* ch. 25, p. 82. (Hum., 1892.)

1907. LIFE, PROCESSES OF, BEYOND VOLITION—*The Physical Man Largely an Automaton—Natural Laws Bear Him On.*—Men need only reflect on the automatic processes of their natural body to discover that this is the universal law of life. What does any man consciously do, for instance, in the matter of breathing? What part does he take in circulating the blood, in keeping up the rhythm of his heart? What control has he over growth? What man by taking thought can add a cubit to his stature? What part voluntarily does man take in secretion, in digestion, in the reflex actions? In point of fact is he not after all the veriest automaton, every organ of his body given him, every function arranged for him, brain and nerve, thought and sensation, will and conscience, all provided for him ready made?—DRUMMOND *Natural Law in the Spiritual World,* essay 8, p. 275. (H. Al.)

1908. LIFE REVERSES RULES OF THE INORGANIC — *Motion Characterizes Life.*—The chemist equally regards chemical change in a body as the effect of the action of something external to the body changed. A chemical compound once formed would persist forever if no alteration took place in surrounding conditions.

But to the student of life the aspect of Nature is reversed. Here, incessant, and, so far as we know, spontaneous change is the rule, rest the exception—the anomaly to be accounted for. Living things have no inertia and tend to no equilibrium.—HUXLEY *Lay Sermons,* serm. 5, p. 73. (A., 1895.)

1909. LIFE RUNS IN GROOVES OF HABIT—*Instinct and Reason.*—When we look at living creatures from an outward point of view, one of the first things that strike us is that they are bundles of habits. In wild animals, the usual round of daily behavior seems a necessity implanted at birth; in animals domesticated, and especially in man, it seems, to a great extent, to be the result of education. The habits to which there is an innate tendency are called instincts; some of those due to education would by most persons be called acts of reason. It thus appears that habit covers a very large part of life, and that one engaged in studying the objective manifestations of mind is bound at the very outset to define clearly just what its limits are.—JAMES *Psychology,* vol. i, ch. 4, p. 104. (H. H. & Co., 1899.)

1910. LIFE, SOCIAL, DEPENDS UPON MOTHERHOOD—*So Ethics and Religion—Through Infancy to the Kingdom of Heaven.*—See then what the savage mother and her babe have brought into the world. When the first mother awoke to her first tenderness and warmed her loneliness at her infant's love, when for a moment she forgot herself and thought upon its weakness or its pain, when by the most imperceptible act or sign or look of sympathy she expressed the unutterable impulse of her motherhood, the touch of a new creative hand was felt upon the world. However short the earliest infancies, however feeble the sparks they fanned, however long heredity took to gather fuel enough for a steady flame, it is certain that once this fire began to warm the cold hearth of Nature and give humanity a heart, the most stupendous task of the past was accomplished. . . . "From of old we have heard the monition, 'Except ye be as babes ye cannot enter the kingdom of heaven'; the latest science now shows us—tho in a very different sense of the words—that unless we had been as babes, the ethical phenomena which give all its significance to the phrase 'Kingdom of heaven' would have been nonexistent for us. Without the circumstances of infancy we might have become formidable among animals through sheer force of sharpwittedness. But except for these circumstances we should never have comprehended the meaning of such phrases as 'self-sacrifice' or 'devotion.' The phenomena of social life would have been omitted from the history of the world, and with them the phenomena of ethics and religion." [Fiske, "Cosmic Philosophy," vol. ii, p. 363.]—DRUMMOND *Ascent of Man,* ch. 8, p. 290. (J. P., 1900.)

1911. LIFE, SOCIAL, QUALITIES THAT GIVE PREEMINENCE IN—*Struggle in Conversation.*—In every conversation there is a victor and a vanquished, not alone because for the moment, or later, the interlocutor renounces [his own] ideas for those of others, but still more because one of the speakers takes, as we say, the *dé* [the die—*i. e.,* the engrossing share] of the conversation. The one takes it, the other allows him to. In general, mental superiority establishes this subordination, but superiority alone is not sufficient. There is also necessary a certain eloquence, a certain dash of assurance and audacity. In the general conversations of the salons these subsidiary qualities are still more indispensable than in friendly chat between two. One who is obscure or unknown discovers that even

in society it would be impossible to seize the world and keep it long enough to set forth his ideas. In the salon, eloquence and audacity are indispensable. We often see also a chatterer not possessing a single original idea exercising great influence upon the drawing-room, while men of real merit are completely effaced by reason of modesty and timidity.—NOVICOW *Les Luttes entre Sociétés humaines et leur Phases successives.* (Translated for *Scientific Side-Lights.)*

1912. LIFE, SPIRITUAL, OF MAN—*Mysterious Communion of Nature with.*—The impression which is left on the mind by the aspect of natural scenery is less determined by the peculiar character of the region than by the varied nature of the light through which we view, or mountain or plain, sometimes beaming beneath an azure sky, sometimes enveloped in the gloom of lowering clouds. Thus, too, descriptions of Nature affect us more or less powerfully in proportion as they harmonize with the condition of our own feelings. For the physical world is reflected with truth and animation on the inner susceptible world of the mind. Whatever marks the character of a landscape—the profile of mountains, which in the far and hazy distance bound the horizon; the deep gloom of pine forests; the mountain torrent, which rushes headlong to its fall through overhanging cliffs—all stand alike in an ancient and mysterious communion with the spiritual life of man. From this communion arises the nobler portion of the enjoyment which Nature affords. —HUMBOLDT *Views of Nature,* p. 154. (Bell, 1896.)

1913. LIFE SUBJUGATES CHEMISTRY—Whatever the relationship may be between living organisms and the elements, or elementary forces of external Nature, it certainly is not the relationship of mere chemical affinities. On the contrary, the union which these affinities by themselves produce can only be reached through the dissolution and destruction of living bodies. The subjugation of chemical forces under some higher form of energy which works them for the continued maintenance of a separate individuality—this is of the very essence of life. The destruction of that separateness or individuality is of the very essence of death.—ARGYLL *Unity of Nature,* ch. 2, p. 34. (Burt.)

1914. LIFE SURROUNDED BY AN ATMOSPHERE OF DESTRUCTION—*Disease a Conflict between Victim and Bacteria.*—But the action of living contagia extends beyond the domain of the surgeon. The power of reproduction and indefinite self-multiplication which is characteristic of living things, coupled with the undeviating fact of contagia "breeding true," has given strength and consistency to a belief long entertained by penetrating minds, that epidemic diseases generally are the concomitants of parasitic life. "There begins to be faintly visible to us a vast and destructive laboratory of Nature wherein the diseases which are most fatal to animal life, and the changes to which dead organic matter is passively liable, appear bound together by what must at least be called a very close analogy of causation." According to this view, which, as I have said, is daily gaining converts, a contagious disease may be defined as a conflict between the person smitten by it and a specific organism which multiplies at his expense, appropriating his air and moisture, disintegrating his tissues, or poisoning him by the decompositions incident to its growth.—TYNDALL *Floating Matter of the Air,* essay 5, p. 288. (A., 1895.)

1915. LIFE, TENACITY OF—*The Oldest Thing Alive in Germany.*—Of all things in the soil of Germany the most tenacious of life is a tender rose. More than eight hundred years ago the rose-bush at the Cathedral of Hildesheim received special care and regard as a venerable, antique monument of the past.—PFUHL *Was geboren ist auf Erden muss zu Erd-Asche werden (17 Serie).* (Translated for *Scientific Side-Lights.)*

1916. LIFE THE CAUSE OF ORGANIZATION—*Science Has No Explanation of Vital Force.*—This [that mind is inconceivable except in connection with a material organ] would be a very unsafe conclusion even if the connection between our bodies and our minds were of such a nature that we could not conceive the separation of the two. But so far is this from being the case that, as Professor Tyndall most truly says, "it is a connection which we know only as an inexplicable fact, and we try to soar in a vacuum when we seek to comprehend it." The universal testimony of human speech—that sure record of the deepest metaphysical truths—proves that we cannot but think of the body and the mind as separate—of the mind as our proper selves, and of the body as indeed external to it. Let us never forget that life, as we know it here below, is the antecedent or the cause of organization, and not its product; that the peculiar combinations of matter which are the homes and abodes of life are prepared and shaped under the control and guidance of that mysterious power which we know as vitality; and that no discovery of science has ever been able to reduce it to a lower level, or to identify it with any purely material force.—ARGYLL *Unity of Nature,* ch. 8, p. 182. (Burt.)

1917. LIFE THE MIGHTIEST OF FORCES—*Living Plants Wedge Dead Rocks Asunder—Prepare New Soil for Their Own Growth.*—Living plants themselves attack rocks, and by means of the acids in their roots dissolve out the mineral matters required by the organisms. Further, their roots penetrate the natural division-planes of rocks and wedge these asunder; and thus, by allowing freer percolation of water, they

prepare the way for more rapid disintegration. Nor can we neglect the action of tunneling and burrowing animals, some of which aid considerably in the work of destruction. There can be no doubt, for example, that worms, as Darwin has shown, play an important part in the formation of soil, which is simply rotted rock plus organic matter.—GEIKIE *Earth Sculpture*, ch. 2, p. 29. (G. P. P., 1898.)

1918. LIFE, TRANSITORINESS OF—*Leaves Scarce a Trace on Earth.*—As to the dry land, so far from being the receptacle of fresh accessions of matter, it is exposed almost everywhere to waste away. Forests may be as dense and lofty as those of Brazil, and may swarm with quadrupeds, birds, and insects, yet at the end of ten thousand years one layer of black mold, a few inches thick, may be the sole representative of those myriads of trees, leaves, flowers, and fruits, those innumerable bones and skeletons of birds, quadrupeds, and reptiles, which tenanted the fertile region. Should this land be at length submerged, the waves of the sea may wash away in a few hours the scanty covering of mold, and it may merely impart a darker shade of color to the next stratum of marl, sand, or other matter newly thrown down.—LYELL *Principles of Geology*, bk. i, ch. 13, p. 188. (A., 1854.)

1919. LIFE, ULTIMATE FACTS OF—Sensation, perception, consciousness, and thought—these, if they are not the very essence of life, are at least—in their order—its highest accompaniments and result. They are the ultimate facts, they are the final realities, to which all lesser adjustments are themselves adjusted.—ARGYLL *Unity of Nature*, ch. 2, p. 34. (Burt.)

1920. LIFE, UNIVERSAL DIFFUSION OF—*Insects on Highest Mountain Peaks—Condor Soars Above the Andes.*—When the active spirit of man is directed to the investigation of Nature, or when in imagination he scans the vast fields of organic creation, among the varied emotions excited in his mind there is none more profound or vivid than that awakened by the universal profusion of life. Everywhere—even near the ice-bound poles—the air resounds with the song of birds and with the busy hum of insects. Not only the lower strata, in which the denser vapors float, but also the higher and ethereal regions of the air, teem with animal life. Whenever the lofty crests of the Peruvian Cordilleras, or the summit of Mont Blanc, south of Lake Leman, have been ascended, living creatures have been found even in these solitudes. On the Chimborazo, which is upwards of eight thousand feet higher than Mount Etna, we saw butterflies and other winged insects. Even if they are strangers carried by ascending currents of air to those lofty regions, whither a restless spirit of inquiry leads the toilsome steps of man, their presence nevertheless proves that the more pliant organization of animals may subsist far beyond the limits of the vegetable world. The condor, that giant among the vultures, often soared above us at a greater altitude than the summits of the Andes.—HUMBOLDT *Views of Nature*, p. 210. (Bell, 1896.)

1921. ———— *Vegetation on Snow, in Caves and Mines, and Under Glaciers.*—The strong and beneficial influence exercised on the feelings of mankind by the consideration of the diffusion of life throughout the realms of Nature is common to every zone, but the impression thus produced is most powerful in the equatorial regions, in the land of palms, bamboos, and arborescent ferns, where the ground rises from the shore of seas rich in mollusca and corals to the limits of perpetual snow. The local distribution of plants embraces almost all heights and all depths. Organic forms not only descend into the interior of the earth where the industry of the miner has laid open extensive excavations and sprung deep shafts, but I have also found snow-white stalactitic columns encircled by the delicate web of an *Usnea* in caves where meteoric water could alone penetrate through fissures. *Podurellæ* penetrate into the icy crevices of the glaciers on Mount Rosa, the Grindelwald, and the Upper Aar; the *Chionæa araneoides* described by Dalman, and the microscopic *Discerea nivalis* (formerly known as *Protococcus*), exist in the polar snow as well as in that of our high mountains. The redness assumed by the snow after lying on the ground for some time was known to Aristotle, and was probably observed by him on the mountains of Macedonia.—HUMBOLDT *Cosmos*, vol. i, p. 344. (H., 1897.)

1922. LIFE, VEGETABLE, LACKING IN OCEAN DEPTHS—It has not been determined yet with any degree of accuracy where we are to place the limit of vegetable life, but it seems probable that below a hundred fathoms no organisms, excepting a few parasitic fungi, are to be found that can be included in the vegetable kingdom. While then the researches of recent times have proved beyond a doubt that there is no depth of the ocean that can be called azoic, they have but confirmed the perfectly just beliefs of the older naturalists that there is a limit where vegetable life becomes extinct. It is not difficult to see the reason for this. All plants, except a few parasites and saprophytes, are dependent upon the influence of direct sunlight, and as it has been shown . . . that the sunlight cannot penetrate more than a few hundred fathoms of seawater, it is impossible for plants to live below that depth.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 42. (A., 1894.)

1923. LIFE VIEWED AS CONTINUOUS—*Reproduction an Essential Attribute.*—Reproduction is in truth an essential attribute of living matter, just as is the growth which gives rise to it. It is as impossible

to imagine life enduring without reproduction as it would be to conceive life lasting without the capacity for absorption of food and without the power of metabolism. Life is continuous and not periodically interrupted: ever since its first appearance upon the earth, in the lowest organisms, it has continued without break: the forms in which it is manifested have alone undergone change. Every individual alive to-day—even the very highest—is to be derived in an unbroken line from the first and lowest forms.—WEISSMAN *Heredity*, vol. i, p. 161. (C. U. P., 1892.)

1924. LIFE, WANTON DESTRUCTION OF—*Grace of Form and Motion of the Great Blue Heron—Irreparable Loss.*—The presence of a stately great blue heron or "crane" adds an element to the landscape which no work of man can equal. Its grace of form and motion, emphasized by its large size, is a constant delight to the eye: it is a symbol of the wild in Nature; one never tires of watching it. What punishment, then, is severe enough for the man who robs his fellows of so pure a source of enjoyment? A rifle-ball turns this noble creature into a useless mass of flesh and feathers; the loss is irreparable. Still, we have no law to prevent it. Herons are said to devour large numbers of small fish. But is not the laborer worthy of his hire? Are the fish more valuable than this, one of the grandest of birds?—CHAPMAN *Bird-Life*, ch. 7, p. 95. (A., 1900.)

1925. LIFE WITHOUT MOTIVE OR PURPOSE—*Sensations without Ideas—The Brainless Pigeon—Spontaneity Destroyed.*—To illustrate this sensori-motor or instinctive action, we may take the results of Flourens's well-known experiment of removing the cerebral hemispheres of a pigeon. What happens? The pigeon seemingly loses at once all intelligence and all power of spontaneous action. It appears as if it were asleep; yet, if thrown into the air, it will fly. If laid on its back, it struggles on to its legs again; the pupil of the eye contracts to light, and, if the light be very bright, the eyes are shut. It will dress its feathers if they are ruffled, and will sometimes follow with a movement of its head the movement of a candle before it; and, when a pistol is fired off, it will open its eyes, stretch its neck, raise its head, and then fall back into its former attitude. It is quite evident from this experiment that general sensibility and special sensations are possible after the removal of the hemispheres; but they are not then transformed into ideas. The impressions of sense reach and affect the sensory centers, but they are not intellectually perceived; and the proper movements are excited, but these are reflex or automatic. There are no ideas, there is no true spontaneity; and the animal would die of hunger before a plateful of food, tho it will swallow it when pushed far enough into its mouth to come within the range of the reflex acts of deglutition.—MAUDSLEY *Body and Mind*, lect. 1, p. 20. (A., 1898.)

1926. LIFTING OF HEAVY STONES BY PRIMITIVE MAN—*Wedges and Cobwork.*—The only puzzle the modern student can have is to conceive how the ancient engineer lifted [such] great weights. If he could lift them he could move them. It was within the ability of a company of American Indians in several areas to hammer down any great stone into any form. It was customary for them, as tribes, to all engage in the same operation in hauling logs, or seines, or boats, or stones, in rowing and dancing. The problem is somewhat like that of Archimedes. "Given a rope long enough and a cribwork strong enough," and any modern savage people will undertake to set up the monuments of Brittany. In point of fact the ancient Americans did quarry single stones weighing three hundred tons, did move them great distances and set them in place. In the copper mines of Michigan was discovered a huge nugget of copper resting still on a mass of cobwork. Around were wedges and mauls, and, by means of shoring up alternate sides after lifting them by wedges, the engineers had hoisted the mass twenty-six feet. This is the only historic example I have found of actual work done.—MASON *Aboriginal American Mechanics* (*Memoirs of the International Congress of Anthropology*, p. 83). (Sch. P. C.)

1927. LIGHT AND SOUND NOT MERE SENSATIONS—*Existent Waves External to Human Organism.*—Until modern science had established its methods of physical investigation, light and sound were known as sensations only; that is to say, they were known in terms of the mental impressions which they immediately produce upon us, and in no other terms whatever. There was no proof that in these sensations we had any knowledge "in themselves" of the external agencies which produce them. But now all this is changed. Science has discovered what these two agencies are "in themselves"; that is to say, it has defined them under aspects which are totally distinct from seeing or hearing, and is able to describe them in terms addressed to wholly different faculties of conception. Both light and sound are in the nature of undulatory movements in elastic media—to which undulations our organs of sight and hearing are respectively adjusted or "attuned." In these organs, by virtue of that adjustment or attuning, these same undulations are "translated" into the sensations which we know. It thus appears that the facts as described to us in this language of sensation are the true equivalent of the facts as described in the very different language of intellectual analysis. The eye is now understood to be an apparatus for enabling the mind instantaneously to appreciate differences of motion which are of almost incon-

ceivable minuteness. The pleasures we derive from the harmonies of color and of sound, altho mere sensations, do correctly represent the movement of undulations in a definite order; whilst those other sensations which we know as discords represent the actual clashing and disorder of interfering waves. Thus it is that in breathing the healthy air of physical discoveries such as these, altho the limitations of our knowledge continually haunt us, we gain nevertheless a triumphant sense of its certainty and of its truth.—ARGYLL *Unity of Nature*, ch. 4, p. 94. (Burt.)

1928. LIGHT A RESULT OF CORRELATION—*The Retina Attuned to Ethereal Vibrations.*—Light itself, therefore, is discovered to be merely a relative term—a word, in short, denoting nothing but an external correlation between the retina and vibrations of a certain kind and quality. Now what is the language which Professor Tyndall is constrained to use in explanation of facts so difficult of conception? It is the language of mechanism, of mental purpose and design. "It is not," he says, "the size of a wave which determines its power of producing light; it is, broadly speaking, *the fitness of the wave to the retina*. The ethereal pulses must follow each other with a certain rapidity of succession before they can produce light, and if their rapidity exceed a certain limit, they also fail to produce light. *The retina is attuned*, if I may use the term, *to a certain range of vibrations*, beyond which, in both directions, it ceases to be of use." These are indeed wonderful correlations which reveal to us fittings and adjustments of which we had no previous conception; but they give us no glimmering, even, of knowledge as to the physical causes which have "attuned" a material organ so as to catch certain ethereal pulsations in the external world, and to make these the means of conveying to man's intelligence the enjoyment and the power of sight.—ARGYLL *Reign of Law*, ch. 5, p. 153. (Burt.)

1929. LIGHT, ARTIFICIAL—*Primitive Methods Lasted Till Recent Times—The Link-boys of London.*—The first illuminants were probably torches made of resinous woods, which will give a flame for a considerable time. Then the resin exuding from many kinds of trees would be collected and applied to sticks or twigs, or to some fibrous materials tied up in bundles, such as are still used by many savage peoples, and were used in the old baronial halls. For outdoor lights torches were used almost down to our times, an indication of which is seen in the iron torch-extinguishers at the doors of many of the older West End houses [of London]; while, before the introduction of gas, link-boys were as common in the streets as match-sellers are now. Then came lamps, formed of small clay cups, holding some melted animal fat and a fibrous wick; and, somewhat later, rushlights and candles; . . . but the three modes of obtaining illumination for domestic purposes remained entirely unchanged in principle, and very little improved, throughout the whole period of history down to the end of the eighteenth century.—WALLACE *The Wonderful Century*, ch. 4, p. 27. (D. M. & Co., 1899.)

1930. LIGHT A SIGN OF UNITY—*Its Waves Pervade All Space.*—Nor is gravitation the only agency which brings home to us the unity of the conditions which prevail among the worlds. There is another: light—that sweet and heavenly messenger which comes to us from the depths of space, telling us all we know of other worlds, and giving us all that we enjoy of life and beauty on our own. . . . Light is a wave, or an undulatory vibration, and such vibrations can only be propagated in a medium which, however thin, must be material. That this substance is at all like the chemical substance that we call "ether," is of course a metaphor. It is a good metaphor only in so far as the vapor of ether represents to us a form of matter which is very thin, invisible, and impalpable. . . . Light, therefore, reveals to us the fact that we are united with the most distant worlds, and with all intervening space, by some ethereal atmosphere, which embraces and holds them all.—ARGYLL *Unity of Nature*, ch. 1, p. 6. (Burt.)

1931. LIGHT AS KNOWN TO ANCIENTS—*Lens at Nineveh—Combination of Lenses Modern—Telescope and Microscope.*—About light the ancients knew more [than about sound]. Their polished metal mirrors, flat and curved, had taught them the first principles of reflection. Nor were they ignorant of refraction; they already knew the familiar experiment of putting a ring in a basin and pouring in water till it becomes visible. A rock-crystal lens has been dug up at Nineveh, and the Greeks and Romans were well acquainted with glass lenses. One is surprised that neither the Arab astronomers, who knew a good deal of optics, nor Roger Bacon, who in the thirteenth century gave an intelligent account of their science, ever seem to have combined two lenses into a telescope. It was not till the seventeenth century that a telescope is plainly mentioned in Holland, and Galileo, hearing of it, made the famous instrument with which he saw Jupiter's moons, and revolutionized men's ideas of the universe. The microscope and telescope may be called inverted forms of one another, and their inventions came nearly together. By these two instruments the range of man's vision has been so vastly extended beyond his unaided eyesight that animalcules under a ten-thousandth of an inch long can now be watched through all the stages of their life, while stars whose distance from the earth is hundreds of thousands of billions of miles

are within the maps of the universe.—Tylor *Anthropology,* ch. 13, p. 326. (A., 1899.)

1932. LIGHT, DEPOLARIZATION OF—*A New Solid Interposed Scatters Darkness.*—When the tourmalins [tourmalin prisms placed in the path of a ray of light] are crossed, the space where they cross each other is black. But the least obliquity on the part of the crystals permits light to get through both. Now suppose, when the two plates are crossed, that we interpose a third plate of tourmalin between them, with its axis oblique to both. A portion of the light transmitted by the first plate will get through this intermediate one. But, after it has got through, its plane of vibration is changed: it is no longer perpendicular to the axis of the crystal in front. Hence it will get through that crystal. Thus, by pure reasoning, we infer that the interposition of a third plate of tourmalin will in part abolish the darkness produced by the perpendicular crossing of the other two plates. I have not a third plate of tourmalin; but the talc or mica which you employ in your stoves is a more convenient substance, which acts in the same way. Between the crossed tourmalins I introduce a film of this crystal with its axis oblique to theirs. You see the edge of the film slowly descending, and, as it descends, light takes the place of darkness. The darkness, in fact, seems scraped away, as if it were something material. This effect has been called, naturally but improperly, *depolarization.*—Tyndall *Lectures on Light,* lect. 3, p. 122. (A., 1898.)

1933. LIGHT, DOUBLE REFLECTION OF, FROM FILMS—*Bubbles as Teachers of Science—Extinction of Waves by Interference Gives Prismatic Colors.*—Whence, then, are derived the colors of the soap-bubble? Imagine a beam of white light impinging on the bubble. When it reaches the first surface of the film, a known fraction of the light is reflected back. But a large portion of the beam enters the film, reaches its second surface, and is again in part reflected. The waves from the second surface thus turn back and hotly pursue the waves from the first surface. And, if the thickness of the film be such as to cause the necessary retardation, the two systems of waves interfere with each other, producing augmented or diminished light, as the case may be.

But, inasmuch as the waves of light are of different lengths, it is plain that, to produce self-extinction in the case of the longer waves, a greater thickness of film is necessary than in the case of the shorter ones. Different colors, therefore, must appear at different thicknesses of the film.—Tyndall *Lectures on Light,* lect. 2, p. 66. (A., 1898.)

1934. LIGHT, ELECTRIC—*Advantages of—Oxygen Not Consumed—Air Not Vitiated—Science Increases Healthfulness and Safety.*—Every other artificial source of light, whether gas, or candles, or oil, takes out of the air the oxygen which is necessary for the support of life, and gives back, in return, carbonic acid, which tends to produce suffocation; whereas the incandescent lamp takes nothing from the air, and it gives nothing to it but pure and simple light. Again, the incandescent lamp produces far less heat . . . for a given amount of illumination than other sources of light. Once more, oil and candles and gas often produce a disagreeable smell, and always produce more or less smoke, which discolors the walls and ceilings of your rooms, injures your paintings and the bindings of your books, and disfigures every kind of decorative work. The incandescent lamp produces no smoke, and what to many is, perhaps, even more important, it produces no smell.

A very remarkable testimony to the healthfulness of the incandescent lamp, as compared with gas, was given by Mr. Preece, at the meeting of the British Association recently held in Bath. About two years ago, the electric light was introduced into the Central Post Office Savings Bank in London, and since that time the leaves of absence, on account of illness, of members of the staff have been reduced by an amount equal to an average of two days a year for each person. This, he said, was equivalent to a gain to the service of the time of eight clerks, and represented a saving of about £640 a year in salaries.

As regards the danger of fire, it is not easy to exaggerate the extraordinary safety of the incandescent lamp. I would only call your attention to one fact. In dealing with gas and candles we are dealing with a naked flame, whose function it is to set fire to whatever touches it; in the case of the incandescent lamp we are dealing with a light shut up in a prison-house of glass, and if we chance to break the glass we at the same moment put out the light.—Molloy *The Electric Light,* lect. 2, p. 37. (Hum., 1889.)

1935. ——— ——— *Scarcely Affects Germs.*—It has been found that the electric light has but little action upon bacteria, tho that which it has is similar to sunlight [*i. e.,* destructive]. Recent experiments with the Röntgen rays have given negative results.—Newman *Bacteria,* ch. 1, p. 25. (G. P. P., 1899.)

1936. LIGHT ESSENTIAL TO GROWTH OF PLANTS—*Sun the Source of Plant-life.*—Light, which is now known to modify many inorganic compounds—light, which works those mechanical changes utilized in photography, causes the combinations of certain gases, alters the molecular arrangements of many crystals, and leaves traces of its action even on substances that are extremely stable—may be expected to produce marked effects on substances so complex and unstable as those which make up organic bodies. . . . The molecular

changes wrought by light in animals are of but secondary moment. . . .

On plants, however, the solar rays that produce in us the impression of yellow, are the immediate agents of those molecular changes through which are hourly accumulated the materials for further growth. Experiments have shown that when the sun shines on living leaves, they begin to exhale oxygen and to accumulate carbon and hydrogen—results which are traced to the decomposition, by the solar rays, of the carbonic acid and water absorbed. It is now an accepted conclusion that, by the help of certain classes of the ethereal undulations penetrating their leaves, plants are enabled to separate from the associated oxygen those two elements of which their tissues are chiefly built up.—SPENCER *Biology*, pt. i, ch. 2, p. 30. (A., 1900.)

1937. LIGHT IN OCEAN DEPTHS—*Few Animals Wholly Blind.*—The conditions in the deep sea are not quite the same [as in terrestrial caves]. In some regions there is probably a very considerable illumination by phosphorescent light, and it is quite possible that many of the characteristic deep-sea forms may occasionally wander into shallower regions where faint rays of sunlight penetrate, or even that the young stages of some species may be passed at or near the surface of the sea. Taking these points into consideration, then, it is not surprising to find that, in the deep seas, there are very few animals, belonging to families usually provided with eyes, that are quite blind.—HICKSON *Fauna of the Deep Sea*, ch 4, p. 68. (A., 1894.)

1938. ——— ——— *Illumination by Phosphorescent Animals—Like a City Street at Night.*—If we may be allowed to compare the light of abysmal animals with that of surface forms, we can readily imagine that some regions of the sea may be as brightly illuminated as a European street is at night—an illumination with many very bright centers and many dark shadows, but quite sufficient for a vertebrate eye to distinguish readily and at a considerable distance both form and color.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 25. (A., 1894.)

1939. LIGHT, LAW OF ITS ABSORPTION—*Each Substance Selects and Stops Its Own Kind of Light—Identification by Spectroscope.*—A general principle first enunciated by Kirchhoff in a communication to the Berlin Academy, December 15, 1859, and afterwards more fully developed by him . . . may be expressed as follows: Substances of every kind are opaque to the precise rays which they emit at the same temperature: that is to say, they stop the kinds of light or heat which they are then actually in a condition to radiate. But it does not follow that cool bodies absorb the rays which they would give out if sufficiently heated. Hydrogen at ordinary temperatures, for instance, is almost perfectly transparent, but if raised to the glowing point—as by the passage of electricity—it then becomes capable of arresting, and at the same time of displaying in its own spectrum, light of four distinct colors.—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 168. (Bl., 1893.)

1940. LIGHT OF PHOSPHORESCENCE IN THE BANDA SEAS—In the Banda Seas, on calm nights, the whole surface of the ocean seems to be a sheet of milky fire. The light is not only to be seen where the crests of waves are breaking, or the surface disturbed by the bows of the boat, but the phosphorescence extends as far as the eye can reach in all directions. It is impossible, of course, to say with any degree of certainty whether phosphorescence such as this exists at the bottom of the deep sea, but it is quite probable that it does in some places, and hence the well-developed eyes and brilliant colors of some of the deep-sea animals.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 26. (A., 1894.)

1941. LIGHT OF SUN HAS HEALTHFUL INFLUENCE—*Represses or Destroys Bacteria.*—Light acts as an inhibitory or even germicidal agent. This fact was first established by Downes and Blunt in a memoir to the Royal Society in 1877. They found by exposing cultures to different degrees of sunlight that thus the growth of the culture was partially or entirely prevented, being most damaged by the direct rays of the sun, altho diffuse daylight acted prejudicially. Further, these same investigators proved that of the rays of the spectrum which acted inimically the blue and violet rays acted most bactericidally, next to the blue being the red and orange-red rays. The action of light, they explain, is due to the gradual oxidation which is induced by the sun's rays in the presence of oxygen.—NEWMAN *Bacteria*, ch. 1, p. 24. (G. P. P., 1899.)

1942. LIGHT PASSES UNCHANGED IN QUALITY THROUGH ABYSMAL SPACES—*Spectrum Analysis in Astronomy.*—Spectrum analysis may be shortly described as a mode of distinguishing the various species of matter by the kind of light proceeding from each. This definition at once explains how it is that, unlike every other system of chemical analysis, it has proved available in astronomy. Light, so far as quality is concerned, ignores distance. No intrinsic change, that we yet know of, is produced in it by a journey from the farthest bounds of the visible universe: so that, provided only that in quantity it remain sufficient for the purpose, its peculiarities can be equally well studied whether the source of its vibrations be one foot or a hundred billion miles distant. Now the most obvious distinction between one kind of light and another resides in color. But of this distinction the eye takes cognizance in an esthetic, not in a scientific sense. It finds gladness in the "thousand tints" of Nature.

but can neither analyze nor define them. Here the refracting prism—or the combination of prisms known as the "spectroscope"—comes to its aid, teaching it to measure as well as to perceive.—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 161. (Bl., 1893.)

1943. LIGHT SIFTED BY NATURAL OBJECTS—*The Color We See Is the Color They Reject.*—Having unraveled the interwoven constituents of white light, we have next to inquire what part the constitution so revealed enables this agent to play in Nature? To it we owe all the phenomena of color, and yet not to it alone; for there must be a certain relationship between the ultimate particles of natural bodies and white light, to enable them to extract from it the luxury of color. But the function of natural bodies is here selective, not creative. There is no color generated by any natural body whatever. Natural bodies have showered upon them, in the white light of the sun, the sum total of all possible colors, and their action is limited to the sifting of that total, the appropriating from it of the colors which really belong to them, and the rejecting of those which do not. It will fix this subject in your minds if I say that it is the portion of light which they reject, and not that which belongs to them, that gives bodies their colors.—TYNDALL *Lectures on Light*, lect. 1, p. 31. (A., 1898.)

1944. LIGHT, TERRESTRIAL, VARIED SOURCES OF—*Phosphorescence of the Ocean.*—As in polar light or the electromagnetic storm, a current of brilliant and often colored light streams through the atmosphere in high latitudes, so also in the torrid zones between the tropics, the ocean simultaneously develops light over a space of many thousand square miles. Here the magical effect of light is owing to the forces of organic Nature. Foaming with light, the eddying waves flash in phosphorescent sparks over the wide expanse of waters, where every scintillation is the vital manifestation of an invisible animal world. So varied are the sources of terrestrial light!—HUMBOLDT *Cosmos*, vol. i, p. 202. (H., 1897.)

1945. LIGHT TRAVERSING PURE WATER—*Undimmed Reflection through Mountain Lake.*—This "gem of the Sierra" [Lake Tahoe] is situated at an elevation of 6,200 feet above the sea, and is enclosed in all directions by rugged, forest-covered mountain slopes which rise from two to over four thousand feet above its surface. Its expanse is unbroken by islands and has an area of between 192 and 195 square miles. . . .

On looking down on Lake Tahoe from the surrounding pine-covered heights, one beholds a vast plain of the most wonderful blue that can be imagined. Near shore, where the bottom is of white sand, the waters have an emerald tint, but are so clear that objects far beneath the surface may be readily distinguished Farther lakeward the tints change by insensible gradation until the water is a deep blue, unrivaled even by the color of the ocean in its deepest and most remote parts. On calm summer days the sky, with its drifting cloud-banks, and the rugged mountains, with their bare and usually snow-covered summits, are mirrored in the placid waters with such wonderful distinctness and such accuracy of detail that one is at a loss to tell where the real ends and the duplicate begins. While floating on the lake in a boat, the transparency of the water gives the sensation that one is suspended in mid-air, as every detail on the bottom, fathoms below, is clearly discernible.

In experimenting on the transparency of the waters, Professor John Le Conte found that a white disk 9.5 inches in diameter, when fastened to a line and lowered beneath the surface, was clearly visible at a depth of 108 feet. It is to be remembered that the light reaching the eye in such an experiment traverses through water twice the distance to which the disk is submerged, or, in the experiment referred to, 216 feet. The only instance in this country in which waters have been found to be more transparent is in the great limestone-water springs of Florida.—RUSSELL *Lakes of North America*, ch. 4, p. 64. (G. & Co., 1895.)

1946. LIGHT, "UNNATURAL," IN SOLAR ECLIPSE—*Hungry Dog Refuses Food—Courtiers of Louis XV.*—I have spoken of the "unnatural" appearance of the light just before totality. This is not due to excited fancy, for there is something so essentially different from the natural darkness of twilight that the brute creation shares the feeling with us. Arago, for instance, mentions that in the eclipse of 1842, at Perpignan, where he was stationed, a dog which had been kept from food twenty-four hours was, to test this, thrown some bread just before "totality" began. The dog seized the loaf, began to devour it ravenously, and then, as the appearance already described came on, he dropped it. The darkness lasted some minutes, but not till the sun came forth again did the poor creature return to the food. It is no wonder, then, that men also, whether educated or ignorant, do not escape the impression. A party of the courtiers of Louis XV. is said to have gathered round Cassini to witness an eclipse from the terrace of the Paris Observatory, and to have been laughing at the populace, whose cries were heard as the light began to fade; when, as the unnatural gloom came quickly on, a sudden silence fell on them too, the panic terror striking through their laughter. Something common to man and the brute speaks at such times, if never before or again; something which is not altogether physical apprehension, but more like the moral dismay when the shock of an earthquake is felt for the first time, and we first know that startling doubt, superior to reason, whether the solid frame of earth is real,

and not " baseless as the fabric of a vision." —LANGLEY *New Astronomy*, ch. 2, p. 41. (H. M. & Co., 1896.)

1947. LIGHT, WAVES OF, ABOLISH EACH OTHER—*Motion of Light Differs from That of Sound.*—On the assumption that light was wave-motion, all his [Thomas Young's] experiments on interference were explained; on the assumption that light was flying particles, nothing was explained. In the time of Huyghens and Euler a medium had been assumed for the transmission of the waves of light; but Newton raised the objection that, if light consisted of the waves of such a medium, shadows could not exist. The waves, he contended, would bend round opaque bodies and produce the motion of light behind them, as sound turns a corner or as waves of water wash round a rock. It was proved that the bending-round referred to by Newton actually occurs, but that the inflected waves abolish each other by their mutual interference. Young also discerned a fundamental difference between the waves of light and those of sound. Could you see the air through which sound-waves are passing, you would observe every individual particle of air oscillating to and fro in the direction of propagation. Could you see the luminiferous ether, you would also find every individual particle making a small excursion to and fro; but here the motion . . . would be across the line of propagation. The vibrations of the air are longitudinal, those of the ether transversal.—TYNDALL *Lectures on Light*, lect. 2, p. 59. (A., 1898.)

1948. LIGHT WHERE SUN'S RAYS NEVER COME—*Rows of Lights on Sides of Deep-sea Fish—The Scopelus.*—We can distinguish two kinds of phosphorescent organs in the deep-sea fish. There are the curious eye-like or ocellar organs situated usually in one or more rows down the sides of the fish's body, forming as it were a series of miniature bull's-eye lanterns to illuminate the surrounding sea, and various glandular organs that may be situated at the extremity of the barbels or in broad patches behind the eyes or in other prominent places on the head and shoulders. Ocellar organs have been known for many years to occur on the sides of the interesting pelagic fish *Scopelus*. Most of the species of this genus live in the open sea at moderate depths, coming to the surface only at night, but other species are found in almost every depth down to 2,000 fathoms of water.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 77. (A., 1894.)

1949. " LIGHTHOUSE OF THE MEDITERRANEAN " — *The Island Volcano of Stromboli.*—Viewed at night-time, Stromboli presents a far more striking and singular spectacle. The mountain, owing to its great elevation, is visible over an area having a radius of more than 100 miles. When watched from the deck of a vessel anywhere within this area, a glow of red light [caused by the light of internal fires reflected from the overhanging cloud of vapor] is seen to make its appearance from time to time above the summit of the mountain; this glow of light may be observed to increase gradually in intensity, and then as gradually to die away. After a short interval the same appearances are repeated, and this goes on till the increasing light of the dawn causes the phenomenon to be no longer visible. The resemblance presented by Stromboli to a " flashing light " on a most gigantic scale is very striking, and the mountain has long been known as " the lighthouse of the Mediterranean."—JUDD *Volcanoes*, ch. 2, p. 10. (A., 1899.)

1950. LIGHTING, METHODS OF—*Torches Reach Down to Modern Days—Greek and Roman Lamps—The Argand Burner.*—Till this century we used torches much as the ancient Romans did, but they are now seldom to be seen, and by their disuse the picturesque side of life loses many striking effects of torchlight glare and shadow on banquet and procession—the delight of painters and poets. Not half the passers-by in old-fashioned streets now know that the extinguishers on the iron railings were to put out the links or torches carried to light the company to their coaches. The candle looks as tho it might have been invented from the torch. The rushlight, made of the pith of the rush dipped in melted fat, was in common use in Pliny's time, as was also the wax or tallow candle with its yarn wick. The old classic lamp was a flattish oval vessel with a nozle (*i. e.*, nostril) at one end for the wick to come out at. Simple as this construction is, it has had a long unchanged use. Museums have few Greek and Roman objects more plentiful than such earthenware lamps, nor more exquisite specimens of metal-work than the bronze ones; and to this day the traveler off the main road in Spain or Italy is lighted to his bedroom with a brass stand-lamp much after the manner of the ancients, with its pickwick hanging to it by a chain. The lamp only came into its improved modern make about a century ago, when Argand let the air in from below, and put on the glass chimney to set up a draft.—TYLOR *Anthropology*, ch. 11, p. 272. (A., 1899.)

1951. LIGHTNING, PHENOMENA OF—*House Struck by—Sleeper Strangely Preserved.*—Professor Henry . . . stated that he had lately examined a house struck by lightning, which exhibited some effects of an interesting kind. The lightning struck the top of the chimney, passed down the interior of the flue to a point opposite a mass of iron placed on the floor of the garret, where it pierced the chimney; thence it passed explosively (breaking the plaster) into a bedroom below, where it came in contact with a copper bell-wire, and passed along this horizontally and silently for about six feet; thence it leaped explosively through the air

a distance of about ten feet, through a dormer window, breaking the sash, and scattering the fragments across the street. It was evidently attracted to this point by the upper end of a perpendicular gutter, which was near the window. It passed silently down the gutter, exhibiting scarcely any mark of its passage until it arrived at the termination, about a foot from the ground. Here again an explosion appeared to have taken place, since the windows of the cellar were broken. A bed, in which a man was sleeping at the time, was situated against the wall, immediately under the bell-wire; and altho his body was parallel to the wire, and not distant from it more than four feet, he was not only uninjured, but not sensibly affected. The size of the hole in the chimney, and the fact that the lightning passed along the copper wire without melting it, show that the discharge was a small one, and yet the mechanical effects, in breaking the plaster, and projecting the window-frame across the street, were astonishingly great.—HENRY *On the Protection of Houses from Lightning, Scientific Writings*, p. 232. (Sm. Inst., 1886.)

1952. LIKENESS OF EMBRYOS OF DIVERSE BEINGS—*Separation Attendant on Development.*—It has been shown that generally the embryos of the most distinct species belonging to the same class are closely similar, but become, when fully developed, widely dissimilar. A better proof of this latter fact cannot be given than the statement by Von Baer that "the embryos of mammalia, of birds, lizards, and snakes, probably also of *Chelonia*, are in the earliest states exceedingly like one another, both as a whole and in the mode of development of their parts; so much so, in fact, that we can often distinguish the embryos only by their size. In my possession are two little embryos in spirit, whose names I have omitted to attach, and at present I am quite unable to say to what class they belong. They may be lizards or small birds, or very young mammalia, so complete is the similarity in the mode of formation of the head and trunk in these animals. The extremities, however, are still absent in these embryos. But even if they had existed in the earliest stage of their development we should learn nothing, for the feet of lizards and mammals, the wings and feet of birds, no less than the hands and feet of men, all arise from the same fundamental form." [Compare GERMS, 1368-70.]—DARWIN *Origin of Species*, ch. 14, p. 458. (Burt.)

1953. LIKENESS, REMARKABLE, OF ANIMAL AND PLANT—*Digestive Fluid of Sundew Resembles Gastric Juice of Animals—A Common Thought Unites Two Kingdoms.*—The glands of *Drosera* [sundew] absorb matter from living seeds which are injured or killed by the secretion. They likewise absorb matter from pollen and from fresh leaves; and this is notoriously the case with the stomachs of vegetable-feeding animals. *Drosera* is properly an insectivorous plant; but as pollen cannot fail to be often blown on to the glands, as will occasionally the seeds and leaves of surrounding plants, *Drosera* is, to a certain extent, a vegetable feeder. . . . There is a remarkable accordance in the power of digestion between the gastric juice of animals with its pepsin and hydrochloric acid, and the secretion of *Drosera* with its ferment and acid belonging to the acetic series. We can, therefore, hardly doubt that the ferment in both cases is closely similar, if not identically the same. That a plant and an animal should pour forth the same, or nearly the same, complex secretion, adapted for the same purpose of digestion, is a new and wonderful fact in physiology.—DARWIN *Insectivorous Plants*, ch. 6, p. 110. (A., 1900.)

1954. LIMBS, LOST, REMNANTS OF—*Rudimentary Organs—Hind Legs of Serpents and Fishes.*—An abundance of the most interesting examples of rudimentary organs is furnished by comparative osteology, or the study of the skeletons of vertebrate animals, one of the most attractive branches of comparative anatomy. In most of the vertebrate animals we find two pairs of limbs on the body, a pair of fore legs and a pair of hind legs. Very often, however, one or the other pair is imperfect; it is seldom that both are, as in the case of serpents and some varieties of eel-like fish. But some serpents, viz., the giant serpents (boa, python), have still in the hinder portion of the body some useless little bones, which are the remains of lost hind legs. In like manner the mammals of the whale tribe (*Cetacea*), which have only fore legs fully developed (breast fins), have further back in their body another pair of utterly superfluous bones, which are remnants of undeveloped hind legs. The same thing occurs in many genuine fishes, in which the hind legs have in like manner been lost.—HAECKEL *History of Creation*, vol. i, ch. 1, p. 14. (K. P. & Co., 1899.)

1955. LIMESTONE, HILLS OF, ONCE BENEATH SEA—*Historical Antiquity Is Geologically Recent.*—We observe in Sicily a lofty table-land and hills, sometimes rising to the height of 3,000 feet, capped with a limestone, in which from 70 to 85 per cent. of the fossil *Testacea* are specifically identical with those now inhabiting the Mediterranean. These calcareous and other argillaceous strata of the same age are intersected by deep valleys which have been gradually formed by denudation, but have not varied materially in width or depth since Sicily was first colonized by the Greeks. The limestone, moreover, which is of so late a date in geological chronology, was quarried for building those ancient temples of Girgenti and Syracuse of which the ruins carry us back to a remote era in

human history. If we are lost in conjectures when speculating on the ages required to lift up these formations to the height of several thousand feet above the sea, how much more remote must be the era when the same rocks were gradually formed beneath the waters!—LYELL *Principles of Geology*, bk. i, ch. 13, p. 185. (A., 1854.)

1956. LIMIT OF HUMAN POWERS —*Measuring Star Distances—The Earth's Orbit Too Narrow—The Distance of but One Star Fairly Measured.*—To measure star distances the earth's dimensions are altogether too small. No instrument which man will ever make would show the slightest difference in the direction of any star as seen from opposite sides of the earth. But precisely as the measurer of the moon's distance need not leave his observatory, or have a companion observer working at a distant station, if he prefers to trust to the earth's rotation to sway his station from one side to the other—so the astronomer, unable to leave the earth to seek, as he would wish, a station millions of miles away, can nevertheless avail himself of the earth's motion of revolution around the sun, which in the course of six months will carry the earth from one side of her path to the opposite side, one hundred and eighty-three millions of miles away. One place and the other (any two opposite points of the earth's orbit) may be regarded as two observing stations at the ends of a base-line of this enormous length, laid down, as it were, to extend astronomical survey from the solar system to the stars.

It might be thought that this base-line could not but be amply sufficient for the purpose in view. But so much vaster are the distances of the stars that until quite recent years this base-line proved altogether too short for effective measurements, and even now only one star has had its distance fairly measured, while some nine or ten have had their distances roughly estimated. All the rest which have been tried lie so far beyond our means of measurement as to show no signs whatever of change of place as the earth circuits around that orbit which to our conceptions seems so enormous in extent.—PROCTOR *Expanse of Heaven*, p. 241. (L. G. & Co., 1897.)

1957. LIMIT OF "PERPETUAL SNOW"—*Snow-line Highest under the Equator—Southern and Northern Slopes Compared—Silent Victory of Sunshine.*—That temperature is a very important factor in determining the height of that line [the snow-line] is obvious, and hence it follows that as a rule the snow-line is higher the nearer the mountains are to the equator. On the south side of Mont Blanc, in the Alps, the limit of perpetual snow is about 9,000 feet above sea-level, while on the Andes, near the equator, it is situated at about the height of 16,000 feet—higher than the highest summit of the Alps. For the same reason the snow-line is usually higher on the side of a mountain exposed to the sun than on the side turned away from it. It is, for example, about 1,000 feet higher on the south than on the north side of the Alps.—CHISHOLM *Nature-Studies*, p. 34. (Hum., 1888.)

1958. LIMIT OF SENSITIVENESS IN RETINA—*Ready Motion Compensates—Wide Field of Vision Secured.*—An optical defect which has long been known to ophthalmologists—the inferiority in the sensitiveness of the retinal surface generally to that of the central spot known as the *macula lutea*—is shown by Professor Helmholtz to be fully compensated by the facility and rapidity with which we move the eye, in such a manner as to bring the image of the object, or of any part of the object, which we wish to examine minutely, upon this sensitive spot; whilst the field over which our vision ranges with sufficient distinctness to see our special object in combination with its surroundings, is far larger than is attainable in any optical instrument of human contrivance.—CARPENTER *Nature and Man*, lect. 15, p. 423. (A., 1889.)

1959. LIMIT OF THE POWER OF THE MICROSCOPE—*Structure that Defies Microscopic Analysis.*—Have the diamond, the amethyst, and the countless other crystals formed in the laboratories of Nature and of man no structure? Assuredly they have; but what can the microscope make of it? Nothing. It cannot be too distinctly borne in mind that between the microscopic limit and the true molecular limit there is room for infinite permutations and combinations. . . . This first marshaling of the atoms, on which all subsequent action depends, baffles a keener power than that of the microscope. When duly pondered, the complexity of the problem raises the doubt, not of the power of our instrument, for that is *nil*, but whether we ourselves possess the intellectual elements which will ever enable us to grapple with the ultimate structural energies of Nature.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 125. (A., 1897.)

1960. LIMIT OF VISUAL FIELD CONCENTRATES ATTENTION—*Practical Perfection of the Eye.*—Now while the disadvantage of the limitation of distinct vision to the *macula lutea* [the sensitive spot of the retina] is thus fully compensated, I hold that this limitation is positively advantageous in this way—that we see the object, or the part of the object, at which we will to look with much greater distinctness than we should do if the whole of the visual picture which we receive at one time were as complete and vivid as that portion of it which is formed on the central spot of the retina. For our mental receptivity of this picture depends upon the attention we give it; so that the more completely our attention is concentrated upon the thing at which we specially wish to look, the more distinctly we see it. The micro-

scopist well knows the great advantage of limiting his field of view when he is examining objects of the greatest difficulty. And every one who has been accustomed to visit picture-galleries is aware how much more fully he is able to appreciate a picture when he looks at it in such a manner that its surroundings are kept out of his view.

To be able to bring our fullest measure of visual power to bear upon any object we desire to examine, and at the same time to see surrounding objects with sufficient distinctness for the recognition of their local relation to it, is, thus, far more advantageous to us than would be the extension of that highest degree of visual power over the whole range at once. Here again, therefore, the asserted imperfection of the eye as an optical instrument proves to be the very contrary, when its structure and action are regarded in their relations to the use we make of the organ, added force being thus given to the final conclusion drawn by Professor Helmholtz that "the adaptation of the eye to its function is most complete, and is seen in the very limits which are set in its defects." Those who quote his previous statement, for the purpose of depreciating the perfection of the organ, are bound in honesty to cite this also.—CARPENTER *Nature and Man*, lect. 15, p. 426. (A., 1889.)

1961. LIMITATION, LAW OF—*Absolute Satisfaction Possible.*—We feel our own ignorance and our own helplessness, not because we have reached, but because we cannot reach, the limits of our intellectual powers, and because the desires which correspond to them are consequently left unsatisfied. This is the difference between ourselves and the lower animals. We can perfectly understand the absolute limitations under which they lie, because in many of our lower faculties we share these limitations with the beasts. All their powers and many of our own are exerted without any sense of limitation, and this because of the very fact that the limitation of them is absolute and complete. In their own nature they admit of no larger use. The field of effort and of attainable enjoyment is, as regards them, coextensive with the whole field in view. Nothing is seen, or felt, or wished for by them which may not be possessed. In such possession all exertion ends and all desire is satisfied. This is the law of every faculty subject to a limit which is absolute; and where this law does not apply, there we may be sure that the limitation is not absolute, but conditional.—ARGYLL *Unity of Nature*, ch. 4, p. 77. (Burt.)

1962. LIMITATION OF IMPULSE AND MOVEMENT—*Fatigue Diminished by Habit.*—The first result of habit is that it simplifies the movements required to achieve a given result, makes them more accurate, and diminishes fatigue.

"The beginner at the piano not only moves his finger up and down in order to depress the key, he moves the whole hand, the forearm, and even the entire body, especially moving its least rigid part, the head, as if he would press down the key with that organ too. Often a contraction of the abdominal muscles occurs as well. Principally, however, the impulse is determined to the motion of the hand and of the single finger. This is, in the first place, because the movement of the finger is the movement *thought of*, and, in the second place, because its movement and that of the key are the movements we try to *perceive*, along with the results of the latter on the ear. The more often the process is repeated, the more easily the movement follows, on account of the increase in permeability of the nerves engaged. But the more easily the movement occurs, the slighter is the stimulus required to set it up; and the slighter the stimulus is, the more its effect is confined to the fingers alone. Thus, an impulse which originally spread its effects over the whole body, or at least over many of its movable parts, is gradually determined to a single definite organ, in which it effects the contraction of a few limited muscles. In this change the thoughts and perceptions which start the impulse acquire more and more intimate causal relations with a particular group of motor nerves."—SCHNEIDER *Der menschliche Wille*, quoted by JAMES in *Psychology*, vol. i, ch. 4, p. 112. (H. H. & Co., 1899.)

1963. LIMITS, FIXED, OF NATURAL SCIENCE—*Ultimate Entities beyond Human Knowledge.*—Natural philosophy has a fixed boundary that she is not permitted to step across. It must be continually remembered in spite of all discoveries that such things as light, electricity, and magnetism cannot be brought into experience because the human intellect has nothing but a representation of things that possess materiality.—LIEBIG *Thierchemie*, p. 8. (Translated for *Scientific Side-Lights.*)

1964. LIMITS OF HUMAN KNOWLEDGE—*Chemistry Stops at Elements—No Human Discovery Goes Beyond.*—When we attempt to break up the various materials around us into simpler parts we soon reach a class of substances which cannot be further decomposed. Simple inspection will show that granite rock, for example, is a mixture of three minerals, called feldspar, mica, and quartz. We know, also, that feldspar consists of alumina, potash, and silica; that mica contains the same materials in different proportions, and that quartz is silica alone. Lastly, the chemists have discovered that alumina is composed of aluminum and oxygen, potash of potassium and oxygen, and silica of silicon and oxygen. But here we must stop; for when you ask us of what these last-named materials are made we find ourselves in the condition of the old philosopher, who got on very well with his flat earth, supporting it on an elephant, and the

elephant on a tortoise, until he came to seek a resting-place for the tortoise; but then his theory failed. So is it with our science. These undecomposed materials are the blocks on which the whole is built, and we are totally ignorant of what lies below. We call all substances which have never yet been decomposed, whatever may be their nature, chemical elements, and of such some seventy are now known.—COOKE *Religion and Chemistry*, ch. 3, p. 86. (A., 1897.)

1965. ——— ——— *Differences Unrecognized—Embryonic Cells Not Identical in Structure.*—When we are told that a moner or an embryo-cell is the early stage of all animals alike, we naturally ask, Is it meant that all these cells are really similar, or is it only that they appear similar to us, and may actually be as profoundly unlike as the animals which they are destined to produce? . . . There is, indeed, the best ground to suppose that the one-celled animals and the embryo-cells referred to have little in common except their general form. We know that the most minute cell must include a sufficient number of molecules of protoplasm to admit of great varieties of possible arrangement, and that these may be connected with most varied possibilities as to the action of forces. Further, the embryo-cell which is produced by a particular kind of animal, and whose development results in the reproduction of a similar animal, must contain potentially the parts and structures which are evolved from it; and fact shows that this may be affirmed of both the embryo- and the sperm-cells where there are two sexes. Therefore it is in the highest degree probable that the eggs of a worm and those of man, tho possibly alike to our coarse methods of investigation, are as dissimilar as the animals that result from them.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 76. (A. B. P. S.)

1966. ——— ——— *Interior of Our Own Earth Unknown—Trivial Explorations.*—In entering upon any speculations or inquiries concerning the nature of the interior of our globe it is necessary before all things that we should clearly realize in our minds how small and almost infinitesimal is that part of the earth's mass which can be subjected to direct examination. The distance from the surface to the center of our globe is nearly 4,000 miles, but the deepest mines do not penetrate to much more than half a mile from the surface, and the deepest borings fall far short of a mile in depth.—JUDD *Volcanoes*, ch. 11, p. 307. (A., 1899.)

1967. ——— ——— *Memory an Ultimate Fact of Consciousness—Science Has No Explanation.*—When, for instance, I recall my graduation-day, and drag all its incidents and emotions up from death's dateless night, no mechanical cause can explain this process, nor can any analysis reduce it to lower terms or make its nature seem other than an ultimate datum, which, whether we rebel or not at its mysteriousness, must simply be taken for granted if we are to psychologize at all. However the associationist may represent the present ideas as thronging and arranging themselves, still, the spiritualist insists, he has in the end to admit that *something*, be it brain, be it "ideas," be it "association," *knows* past time *as* past, and fills it out with this or that event. And when the spiritualist calls memory an "irreducible faculty" he says no more than this admission of the associationist already grants.—JAMES *Psychology*, vol. i, ch. 1, p. 2. (H. H. & Co., 1899.)

1968. ——— ——— *Science Must Leave Some Transcendent Problems Unsolved—Great Value of the Saying, "I Don't Know."*—The astronomer has no choice but to deal with the evidence supplied to him. It would be very convenient if he would invent evidence, and he might in this way give a much more striking and satisfactory account of the mysteries of the star depths. But what we want is the truth; and the truthful astronomer must often be content to give that answer which was the favorite reply, we are told, of the eminent French mathematician, Lagrange, "I don't know."

I remember how on one occasion I was asked, at the close of a lecture on the star depths, why I had not told my audience the true shape of the sidereal universe—that is, its relative length, breadth, and depth. I replied in effect that before I could give this information I must first possess it myself, and that as yet no man possessed it. I could perceive that the audience were very far from satisfied with this reply. But I might have occasioned even more dissatisfaction if I had said, what is in all probability the real truth, that not only is man now ignorant of the configuration of the sidereal universe, but he can never hope to attain exact knowledge on the subject.—PROCTOR *Expanse of Heaven*, p. 80. (L. G. & Co., 1897.)

1969. LIMITS OF HUMAN PERCEPTION HIDE CELESTIAL GLORY—*Saturn as Revealed by Telescope.*—We turn on Saturn a powerful telescope on some calm, clear night, when the air is well suited for observation, and we see the most beautiful picture conceivable—a glorious orb, the surface resplendent with the most beautiful colors, blue at the poles, yellow elsewhere, crossed by a creamy white central belt, and flecked with spots which under favorable circumstances show brown, and purple, and ruddy tints. The most wonderful part of the picture, however, is the amazing ring-system, not a mere ring, as it is so often shown, but a complex system of rings, each curiously variegated in color, while the innermost (richly purple under favorable observing conditions) is unique among celestial objects in being transparent, so that

the orb of the planet can be seen through this "crape-veil ring," as astronomers have called it.—PROCTOR *Expanse of Heaven*, p. 94. (L. G. & Co., 1897.)

1970. LIMITS OF HUMAN THOUGHT—*Infinite Minuteness and Infinite Vastness Baffle.*—What notion can you form of the magnitude of such particles [the ultimate particles of matter]? The distances of stellar space give us simply a bewildering sense of vastness, without leaving any distinct impression on the mind; and the magnitudes with which we have here to do bewilder us equally in the opposite direction. We are dealing with infinitesimals, compared with which the test-objects of the microscope are literally immense.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 122. (A., 1897.)

1971. ——— ——— *The Infinity of Space.*—We cannot think of space as finite, for wherever in imagination we erect a boundary we are compelled to think of space as existing beyond it. Thus by the incessant dissolution of limits we arrive at a more or less adequate idea of the infinity of space.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 3. (A., 1897.)

1972. ——— ——— *The Universe Unsolved.*—I compare the mind of man to a musical instrument with a certain range of notes, beyond which in both directions exists infinite silence. The phenomena of matter and force come within our intellectual range; but behind, and above, and around us the real mystery of the universe lies unsolved, and, as far as we are concerned, is incapable of solution.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 393. (A., 1900.)

1973. LIMITS OF PHYSICAL SCIENCE—*Never Satisfies Soul.*—Lange considers the relation of Epicurus to the gods subjective; the indication, probably, of an ethical requirement of his own nature. We cannot read history with open eyes or study human nature to its depths, and fail to discern such a requirement. Man never has been and he never will be satisfied with the operations and products of the understanding alone; hence physical science cannot cover all the demands of his nature.—TYNDALL *Fragments of Science*, vol. ii, ch. 9, p. 141. (A., 1897.)

1974. LIMITS OF THE DOCTRINE OF EVOLUTION—Facts of this kind [permanence of various species from geologic times] are undoubtedly fatal to any form of the doctrine of evolution which postulates the supposition that there is an intrinsic necessity, on the part of animal forms which have once come into existence, to undergo continual modification; and they are as distinctly opposed to any view which involves the belief that such modification as may occur must take place at the same rate in all the different types of animal or vegetable life. The facts, as I have placed them before you, obviously directly contradict any form of the hypothesis of evolution which stands in need of these two postulates.—HUXLEY *American Addresses*, lect. ii, p. 38. (A., 1898.)

1975. LIMITS TO EDUCATIONAL USE OF SCIENTIFIC THEORIES—I have never advocated the introduction of the theory of evolution into our schools. I should even be disposed to resist its introduction before its meaning had been better understood and its utility more fully recognized than it is now by the great body of the community. The theory ought, I think, to bide its time until the free conflict of discovery, argument, and opinion has won for it this recognition.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 399. (A., 1900.)

1976. LIMITS TO MAGNIFYING POWER OF TELESCOPE—The exceedingly high magnifying powers employed by Herschel constituted a novelty in optical astronomy to which he attached great importance. Yet the work of ordinary observation would be hindered rather than helped by them. The attempt to increase in this manner the efficacy of the telescope is speedily checked by atmospheric, to say nothing of other difficulties. Precisely in the same proportion as an object is magnified, the disturbances of the medium through which it is seen are magnified also. Even on the clearest and most tranquil nights the air is never for a moment really still. The rays of light traversing it are continually broken by minute fluctuations of refractive power caused by changes of temperature and pressure, and the currents which these engender. With such luminous quiverings and waverings the astronomer has always more or less to reckon; their absence is simply a question of degree; if sufficiently magnified, they are at all times capable of rendering observation impossible.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 137. (Bl., 1893.)

1977. LINKS BETWEEN EUROPEAN AND AMERICAN SPECIES—*Bison and Bear in New and Old World.*—If species were in reality unconnected by common ancestors, then it would necessarily follow that, as our knowledge of any group increased, the separations between the different species would become more and more unmistakable. On the contrary, however, it is a well-known fact that the difficult genera become still more difficult as they are more profoundly studied. If, indeed, we consider existing forms only, no doubt the distinctions between the greater number of species are well marked, nor does any one expect to find a living series of links between them. The intermediate forms lived in Tertiary and Quaternary times. Thus, directly we commence to study the extinct forms, all the convenient lines of separation gradually thin out. . . . To take only two cases from the group of Quaternary mammalia, . . . the European and American bisons,

which are now quite distinct, are connected by the *Bison priscus*, while between our brown bear and the grizzly bear of the Rocky Mountains a series of links has been discovered among the abundant remains in the bone-caves.—AVEBURY *Prehistoric Times*, ch. 9, p. 289. (A., 1900.)

1978. LISBON, EARTHQUAKE OF—*Sixty Thousand Persons Perish in Six Minutes.*—In no part of the volcanic region of southern Europe has so tremendous an earthquake occurred in modern times as that which began on the 1st of November, 1755, at Lisbon. A sound of thunder was heard underground, and immediately afterwards a violent shock threw down the greater part of that city. In the course of about six minutes sixty thousand persons perished. The sea first retired and laid the bar dry; it then rolled in, rising fifty feet or more above its ordinary level. The mountains of Arrabida, Estrella, Julio, Marvan, and Cintra, being some of the largest in Portugal, were impetuously shaken, as it were, from their very foundations; and some of them opened at their summits, which were split and rent in a wonderful manner, huge masses of them being thrown down into the subjacent valleys. Flames are related to have issued from these mountains, which are supposed to have been electric; they are also said to have smoked, but vast clouds of dust may have given rise to this appearance.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 495. (A., 1854.)

1979. LOCATION OF OBJECTS IN SPACE—*Due to Joint Action of the Two Eyes.*—With the reference of objects to different distances in space, the world of perception is placed outside of us, and is differentiated into an infinite diversity of content. Altho the spatial relations which we ascribe to external objects may at the outset often be incomplete and deceptive, still the decisive step has been taken with the very introduction of those relations. The ceaseless activity of our sense-perception is constantly at work in the endeavor to perfect our ideas. It furnishes us with new ideational groups, and corrects the most serious errors in those already acquired. All the senses cooperate in this work, each revising and supplementing the others. But it is primarily the common action of the two coordinate organs of vision to which we owe the greatest part of our ideational development. There are no other organs which so directly supplement and correct each other's perceptions, and which thus give so great an impulse to the fusion of separate perceptions into a single idea, as the two eyes.—WUNDT *Psychology*, lect. 12, p. 181. (Son. & Co., 1896.)

1980. LOCKJAW, OR TETANUS, IN GRASP OF SCIENCE—*Infection, Insignificant, Producing Terrible Result—Cure by Opposing Evil in Its Stronghold.*—Tetanus occurs in man and horses most commonly, tho it may affect other animals. There is usually a wound, often an insignificant one, which may occur in any part of the body. The popular idea that a severe cut between the thumb and the index-finger leads to tetanus is without scientific foundation. As a matter of fact, the wound is nearly always on one or other of the limbs, and is infected simply because they come more into contact with soil and dust than does the trunk. It is not the locality of the wound nor its size that affects the disease. A cut with a dirty knife, a gash in the foot from the prong of a gardener's fork, the bite of an insect, or even the prick of a thorn has before now set up tetanus. Wounds which are jagged, and occurring in absorptive tissues, are those most fitted to allow the entrance of the bacillus. The wound forms a local manufactory, so to speak, of the bacillus and its secreted poisons; the bacillus always remains in the wound, but the toxins may pass throughout the body, and are especially absorbed by the cells of the central nervous system, and thus give rise to the spasms which characterize the disease. . . . Evidence has recently been forthcoming at the Pasteur Institute to support the theory that tetanus is a nervous disease, more or less allied to rabies, and is best treated by intracerebral injections of antitoxin, which then has an opportunity of opposing the toxins at their favorite site.—NEWMAN *Bacteria*, ch. 5, p. 168. (G. P. P., 1899.)

1981. LOCOMOTION, PRIMITIVE—*Men as Carriers—First Carriage in England—First Stage-coaches.*—In all previous ages the only modes of traveling or of conveying goods for long distances were by employing either men or animals as the carriers. Wherever the latter were not used all loads had to be carried by men, as is still the case over a large part of Africa, and as was the case over almost the whole of America before its discovery by the Spaniards.

But throughout Europe and Asia the horse was domesticated in very early times, and was used for riding and in drawing war chariots; and throughout the Middle Ages packhorses were in universal use for carrying various kinds of goods and produce, and saddle-horses for riding. All journeys were then made on horseback, and it was in comparatively recent times that wheeled vehicles for traveling in came into general use in England. The very first carriage was made for Queen Elizabeth in 1568; the first that plied for hire in London were in 1625, and the first stage-coaches in 1659.—WALLACE *The Wonderful Century*, ch. 1, p. 5. (D. M. & Co., 1899.)

1982. LOGIC AND SCIENCE—*Invariability of Natural Law.*—There are scientific men who assert that the interposition of Providence is impossible and prayer an absurdity, because the laws of Nature are proved invariable. Inferences are drawn not so much from particular sciences as from

the logical nature of science itself. Now I may state that my own studies in logic lead me to call in question such negative inferences. Laws of Nature are uniformities observed to exist in the action of certain material agents, but it is logically impossible to show that all other agents must behave as they do.—JEVONS quoted by STUCKENBERG *Int. to the Study of Philosophy*, p. 403. (A. & S., 1892.)

1983. LOGIC NO GUARANTY OF TRUTH—That a conclusion is deduced by the strictest logical method from an uncertain premise does not give it a hair's breadth of certainty or of value.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 213. (L. G. & Co., 1898.)

1984. LOGIC OF PLAY—*Founds on Native Impulses.*—The impulse to play in special ways is certainly instinctive. . . . All simple active games are attempts to gain the excitement yielded by certain primitive instincts, through feigning that the occasions for their exercise are there. They involve imitation hunting, fighting, rivalry, acquisitiveness, and construction, combined in various ways; their special rules are habits, discovered by accident, selected by intelligence, and propagated by tradition; but unless they were founded in automatic impulses, games would lose most of their zest.—JAMES *Psychology*, vol. ii, ch. 24, p. 427. (H. H. & Co., 1899.)

1985. LONELINESS, DELIGHT IN—*Larger Fellowship with Universe.*—I was soon upon the ice, once more alone, as I delight to be at times. As a habit going alone is to be deprecated, but sparingly indulged in it is a great luxury. There are no doubt moods when the mother is glad to get rid of her offspring, the wife of her husband, the lover of his mistress, and when it is not well to keep them together. And so, at rare intervals, it is good for the soul to feel the full influence of that "society where none intrudes." When the work is clearly within your power, when long practise has enabled you to trust your own eye and judgment in unraveling crevasses, and your own ax and arm in subduing their more serious difficulties, it is an entirely new experience to be alone amid those sublime scenes. The peaks wear a more solemn aspect, the sun shines with a more effectual fire, the blue of heaven is more deep and awful, and the hard heart of man is often made as tender as a child's. You contract a closer friendship for the universe in virtue of your more intimate contact with its parts.—TYNDALL *Hours of Exercise in the Alps*, ch. 10, p. 116. (A., 1898.)

1986. LONGEVITY AMONG THE JEWS—*Relatively Slight Infant Mortality*—The duration of life among the Israelites is notably much greater than that among Christians. Even in infancy the mortality of the first is relatively less than that of the latter. In the county of Wieselburg, where observations were made for twenty-three years, the mortality during the first year of life was as follows:

Among	1,000 Jewish children	41	deaths
"	1,000 German "	123	"
"	1,000 Hungarian "	167	"
"	1,000 Croatian "	146.9	"

The age of twenty is attained:

By 520.0 Jews in a thousand.
" 513.0 Germans in Altenburg.
" 445.8 Hungarians in Mether.
" 395.4 Croats in Galtendorf.

According to these results, the average life for the Israelites is 46.5 years, for the Germans 26.7, for the Croats 20.2; for the Hungarians the absence of statistics of birth prevents an estimate. For Austria the average age is 27.5.—GALTERS *Die Lebens-Chancen der Israeliten gegenüber den christlichen Confessionen: biostatische Studien (Vierteljahrsschrift für die praktische Heilkunde, Band ii*, p. 19). (Translated for *Scientific Side-Lights.*)

1987. LONGEVITY A RESULT OF ADVANCED CIVILIZATION—*Science Lengthens Human Life.*—Systems of philosophy and forms of religion find a measure of their influence on humanity in census returns. . . . As Dr. Jarvis, in his report to the Massachusetts Board of Health, has stated, at the epoch of the Reformation, "the average longevity in Geneva was 21.21 years; between 1814 and 1833 it was 40.68; as large a number of persons now live to seventy years as lived to forty three hundred years ago. In 1693 the British Government borrowed money by selling annuities on lives from infancy upward, on the basis of the average longevity. The contract was profitable. Ninety-seven years later another tontine, or scale of annuities, on the basis of the same expectation of life as in the previous century, was issued. These latter annuitants, however, lived so much longer than their predecessors that it proved to be a very costly loan for the government. It was found that while ten thousand of each sex in the first tontine died under the age of twenty-eight, only five thousand seven hundred and seventy-two males and six thousand four hundred and sixteen females in the second tontine died at the same age one hundred years later."—DRAPER *Conflict between Religion and Science.* (A., 1875.)

1988. LOSS, APPARENT, OF NITROGEN—*Bacteria Restore It to the Soil.*—In the ordinary processes of vegetation there is a gradual draining of the soil and a passing of nitrogen into the sea; the products of decomposition pass from the soil by this drainage, and are "lost" as far as the soil is concerned. Many of the methods of sewage-disposal are in reality depriving the land of the return of nitrogen which is its necessity. Again, nitrogen is freed in explosions of gunpowder, nitroglycerin, and dynamite, for whatever purpose they are used. Hence the great putrefactive "loss" of nitrogen,

with its subsidiary losses, contributes to reduce this essential element of all life; and if there were no method of bringing it back again to the soil it would seem that plant-life, and therefore animal-life, would speedily terminate.

It is at this juncture, and to perform this vital function, that the nitrogen-fixing [nitrifying] bacteria play their wonderful part: they bring back the free nitrogen and fix it in the soil.—Newman *Bacteria*, ch. 5, p. 160. (G. P. P., 1899.)

1989. LOSS NOT EASILY REPAIRED —*Removal of Earth's Vegetable Covering—Deserts May Remain Desolate for Ages.*—The origin of this absence of plants over large tracts of land, in regions characterized on every side by the most exuberant vegetation, is a geological phenomenon which has hitherto received but little attention; it undoubtedly arises from former revolutions of Nature, such as inundations, or from volcanic convulsions of the earth's surface. When once a region loses its vegetable covering, if the sand is loose and devoid of springs, and if vertically ascending currents of heated air prevent the precipitation of vapor, thousands of years may elapse before organic life can penetrate from the green shores to the interior of the dreary waste.—Humboldt *Views of Nature*, p. 216. (Bell, 1896.)

1990. LOSS OF PRIMITIVE SIMPLICITY—*Civilization Not an Unmixed Gain —Womanly Arts Not Improved.*—There ought to be no doubt that in every case where the savage was fortunate enough to obtain the knife, his carving and whittling were better done. There is a marvelous difference between carving, on the one hand, man's work chiefly, and basketry or pottery, on the other, conservative woman's work. In no tribes were the two last-named arts bettered by contact with the higher race. The work was done with the hands almost wholly. The tools were of the simplest character. The harsh iron awl was not so good as the smooth-pointed bone awl, of which hundreds have been found, and the pride in personal endeavor departed with the quenching of the tribal spirit. The potter's wheel, such as it was three centuries ago, was only a barrier to the unmechanical sex. Therefore those who constantly assert that prejudice made it impossible for the savage to better himself in the adoption of the white man's devices catch only half a truth.—Mason *The Man's Knife among the North American Indians (Report of the U. S. National Museum for 1897*, p. 727).

1991. LOSS THROUGH DISUSE—*Atrophy of Optic Nerve—The Mole Has True Eyes.*—This animal [the mole], whose peculiar habits are known to every one, has true eyes, from which none of the essential parts of the eyes of the Vertebrata are absent, altho these parts are all of the simplest, almost of embryonic structure. The whole eye is very small, deeply embedded in muscles, and quite covered by the skin, so that it is quite invisible externally. The lens consists of a very small number of minute and little altered embryonic cells; the retina, in the same way, is much simpler than in the eyes of other Vertebrata. True degeneration, then, such as makes the eye incapable of seeing, has not taken place; nevertheless the eye of the mole is reduced to almost total inefficiency even when by chance it has an opportunity for using it. This almost total blindness in the mole is the result solely of complete degeneration of the optic nerve, so that the images which are probably formed in the eye itself can never be transmitted to the animal's consciousness. Occasionally, however, the mole even can see a little, for it has been found that both optic nerves are not always degenerate in the same individual, so that one eye may remain in communication with the brain while the other has no connection with it. In the embryo of the mole, however, and without exception, both eyes are originally connected with the brain by well-developed optic nerves, and so theoretically efficient. This may indeed be regarded as a perfectly conclusive proof that the blind mole is descended from progenitors that could see; it would seem, too, to prove that the blindness of the fully grown animal is the result, not of inheritance, but of the directly injurious effects of darkness on the optic nerve in each individual.—Semper *Animal Life*, ch. 3, p. 79. (A., 1881.)

1992. ———— *Atrophy of Wings of Great Auk.*—One of the characteristic water-birds of our North Atlantic coasts is the razor-billed auk. . . . During the winter it migrates southward as far as Long Island. Flight is therefore a necessary faculty, and we find the bird with well-developed wings, which it uses effectively. We can, however, imagine conditions under which it would not be necessary for the razor-bill to fly. It might become a permanent resident of isolated islands, laying its egg on accessible beaches. Already an expert diver, obtaining its food in the water, it would not be obliged to rise into the air, and, as a result of disuse, the wings would finally become too small to support it in aerial flight, tho fully answering the purpose of oars. Apparently this is what has happened in the case of the razor-billed auk's relative, the flightless, extinct great auk. The razor-bill is sixteen inches long and its wing measures eight inches, while the great auk, with a length of thirty inches, has a wing only five and three-fourths inches in length. Aside from this difference in measurements these birds closely resemble each other. So far as we are familiar with the great auk's habits, they agreed with those of the hypothetical case I have just mentioned, and we are warranted, I think,

in assuming that the bird lost the power of flight through disuse of its wings.—CHAPMAN *Bird-Life*, ch. 2, p. 20. (A., 1900.)

1993. ——— ——— *Magnet Must Work or Perish—Man Made for Usefulness.*—If made of the best of steel for the purpose, and hardened and tempered in just the right way, [the magnet] will hold its charge if it is given something to do. If a piece of iron is placed across its poles it also becomes a magnet, and its molecules turn and work in harmony with those of the mother-magnet. These magnetic lines of force reach around in a circuit. Even before the iron, or "keeper," as it is called, is put across its poles there are lines of force reaching around through the air or ether from one pole to another. . . . As long as we give our magnet something to do, up to the measure of its capacity, it will keep up its power. We may make other magnets with it—thousands, yea, millions of them—and it not only does not lose its power, but may be even stronger for having done this work. If, however, we hang it up without its "keeper," and give it nothing to do, it gradually returns to its natural condition in the home circle of molecular rings. Little by little the coercive force is overcome by the constant tendency of the molecule to go back to its natural position among its fellows.

The magnet furnishes many beautiful lessons, as indeed do all the natural phenomena. Every man has within him a latent power that needs only to be aroused and directed in the right way to make his influence felt upon his fellows. Like the magnet, the man who uses his power to help his fellows up to the measure of his limitations not only has been a benefactor to his race, but is himself a stronger and better man for having done so. But, again, like the magnet, if he allows these God-given powers to lie still and rust for want of legitimate use he gradually loses the power he had and becomes simply a moving thing without influence or use in a world in which he vegetates.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 4, p. 30. (F. H. & H., 1900.)

1994. ——— ——— *Parasites among Plants.*—Among a number of plants the power of self-assimilation has been entirely lost. They develop no green leaves, but have the peculiarity of penetrating the roots and the main stalk of other plants with their rootlets, of intergrowing with them completely, and of employing for themselves the combinations of carbon prepared by other plants for their own use.—ENGLER *Ueber das Pflanzenleben unter der Erde.* (Translated for *Scientific Side Lights.*)

1995. LOVE CONVERTS PAIN TO JOY—*Any Strong Emotion Makes Man Insensible to Pain.*—It is as truly our nature not to feel pain from the ordinarily painful things at some times as it is to feel them painful at others. In this respect, the power of love to take away pain is not peculiar. Love, when it is strong, can banish pain; but in this it is only like all strong emotions: it is peculiar in its power of making what is ordinarily painful a source of joy, and this a joy of the highest and most exquisite kind. We all know this. We not only are willing, we rejoice, to bear an ordinarily painful thing for the benefit or pleasure of one whom we intensely love. Within certain limits, indeed, but still most truly, the bearing pain for such an end is a privilege to be sought, not a sorrow to be shunned. Universal experience proves this: it is one of the broad, familiar features of human life.—HINTON *The Mystery of Pain*, p. 20. (Hum., 1893.)

1996. LOVE NOT A PRODUCT OF SEX OR MARRIAGE—*Loveless Wedlock among Savages—The Child Awakened Love—United Parents.*—With all [other] barriers removed it might now be supposed that the process was at last complete. But one of the surprises of evolution here awaits us. All the arrangements are finished to fan the flame of love, yet out of none of them was love itself begotten. The idea that the existence of sex accounts for the existence of love is untrue. Marriage among early races . . . has nothing to do with love. Among savage peoples the phenomenon everywhere confronts us of wedded life without a grain of love. Love, then, is no necessary ingredient of the sex relation; it is not an outgrowth of passion. Love is love, and has always been love, and has never been anything lower. Whence, then, came it? If neither the husband nor the wife bestowed this gift upon the world, who did? It was a little child. Till this appeared, man's affection was non-existent; woman's was frozen. The man did not love the woman; the woman did not love the man. But one day from its mother's very heart, from a shrine which her husband never visited nor knew was there, which she herself dared scarce acknowledge, a child drew forth the first fresh bud of a love which was not passion, a love which was not selfish, a love which was an incense from its Maker, and whose fragrance from that hour went forth to sanctify the world. Later, long later, through the same tiny and unconscious intermediary, the father's soul was touched. And one day, in the love of a little child, father and mother met.—DRUMMOND *Ascent of Man*, ch. 9, p. 305. (J. P., 1900.)

1997. LOVE, THE MOTHER'S, UNRIVALED—The passionate devotion of a mother—ill herself, perhaps—to a sick or dying child is perhaps the most simply beautiful moral spectacle that human life affords. Contemning every danger, triumphing over every difficulty, outlasting all fatigue, woman's love is here invincibly su-

perior to anything that man can show.—JAMES *Psychology*, vol. ii, ch. 24, p. 440. (H. H. & Co., 1899.)

1998. LUXURIANCE OF NATURE—*Rapid Growth of Coral.*—The reefs on which these corals grow are very irregular in form, are full of cavities, and have not a solid flat surface of dead rock, like that surrounding the lagoon; nor can they be nearly so hard, for the inhabitants by the aid of crowbars made a channel of considerable length through these reefs, in which a schooner, built on the southeast islet, was floated out. It is a very interesting circumstance that this channel, altho made less than ten years before our visit, was then, as we saw, almost choked up with living coral, so that fresh excavations would be absolutely necessary to allow another vessel to pass through it.—DARWIN *Coral Reefs*, ch. 1, p. 19. (A., 1900.)

1999. LUXURIANCE OF TROPICS—*Forest Superimposed on Forest.*—There seems to be no forest region in the world comparable with that of Brazil; for the dreary one of Africa, described by Stanley, appears far inferior in the development of its trees. But in Brazil, as Alfred Wallace has so graphically described, forest is fitted to and superimposed on forest. At a great height a waving sea of verdure, rich with animal life, is spread out in the dazzling sunshine, borne up on columns which tower through the obscurity of the vast space beneath, wherein a second growth of what would elsewhere seem noble trees finds a congenial home. Beneath these, again, there may yet be another similar but smaller growth, while lycopods and a multitude of humbler herbs clothe the soil.—MIVART *Types of Animal Life*, ch. 1, p. 3. (L. B. & Co., 1893.)

2000. LUXURY A CAUSE OF DEGENERACY—When a bird which has been accustomed to seek its food in trees and bushes finds upon the ground supplies so rich as to afford better sustenance, it will gradually come to live more and more upon the ground, and less and less in trees, a fact which taken alone will entirely alter the conditions of its life. It will not require to fly, and will consequently fly less and less often, and after the lapse of generations will cease to fly altogether. And to bring all this about, the wood in which it lives, the climate, the surrounding animals, need not have undergone any changes; merely the adoption of a new habit by the bird itself will suffice.—WEISMANN *Heredity*, vol. ii, p. 4. (Cl. P., 1892.)

2001. MACHINE DISTRIBUTES ENERGY—*The Coiled Spring.*—Another form of stored energy is manifested in the winding up of a weight or spring; the amount of power that has been expended in winding up the weight may be utilized in its descent when released to drive machinery, as of a clock, and perform various kinds of work. The function of a machine, and its only function, is to distribute energy that has been stored, in a manner that will be most convenient for our purposes.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 2, p. 22. (F. H. & H., 1900.)

2002. MACHINE HAS NO INHERENT POWER—*A Product of Mind, but External and Objective.*—[The] essential element in our idea of a machine is that its powers, whatever they may be, are derived, and not original. There may be great knowledge in the work done by a machine, but the knowledge is not in it. There may be great skill, but the skill is not in it; great foresight, but the foresight is not in it; in short, great exhibition of all the powers of mind, but the mind is not in the machine itself. Whatever it does is done in virtue of its construction, which construction is due to a mind which has designed it for the exhibition of certain powers and the performance of certain functions. These may be very simple or they may be very complicated; but whether simple or complicated, the whole play of its operations is limited and measured by the intentions of its constructor. If that constructor be himself limited either in opportunity, or knowledge, or in power, there will be a corresponding limitation in the things which he invents and makes. Accordingly, in regard to man, he cannot make a machine which has any of the gifts and the powers of life. He can construct nothing which has sensibility or consciousness or any other of even the lowest attributes of living creatures. And this absolute destitution of even apparent originality in a machine—this entire absence of any share of consciousness, or of sensibility, or of will—is one part of our very conception of it.—ARGYLL *Unity of Nature*, ch. 3, p. 57. (Burt.)

2003. MACHINE NEVER CREATES POWER—No engine, however subtly devised, can evade this law of equivalence, or perform on its own account the smallest modicum of work. The machine distributes, but it cannot create.—TYNDALL *Heat a Mode of Motion*, lect. 3, p. 83. (A., 1900.)

2004. MACHINE, THE HUMAN BODY A—*Digestion of Food—Breathing—Voluntary Movements.*—Most undoubtedly, the digestion of food in the human body is a purely chemical process; and the passage of the nutritive parts of that food into the blood, a physical operation. Beyond all question, the circulation of the blood is simply a matter of mechanism, and results from the structure and arrangement of the parts of the heart and vessels, from the contractility of those organs, and from the regulation of that contractility by an automatically acting nervous apparatus. The progress of physiology has further shown that the contractility of the muscles and the irritability of the nerves are purely the

results of the molecular mechanism of those organs; and that the regular movements of the respiratory, alimentary, and other internal organs are governed and guided as mechanically by their appropriate nervous centers. The even rhythm of the breathing of every one of us depends upon the structural integrity of a particular region of the medulla oblongata, as much as the ticking of a clock depends upon the integrity of the escapement. You may take away the hands of a clock and break up its striking machinery, but it will still tick; and a man may be unable to feel, speak, or move, and yet he will breathe.—HUXLEY *Lay Sermons*, serm. 14, p. 334. (G. P. P., 1899.)

2005. ——— ——— *Soul the Directing Agent, Not the Motive Power.*—The human body is itself an admirably contrived complex machine, furnished with levers, pulleys, cords, valves, and other appliances for the application and modification of the power derived from the food. It is, in fact, a locomotive-engine, impelled by the same power which under another form gives activity and energy to the iron horse of the railway. In both, the power is derived from combustion of the carbon and hydrogen of the organic matter employed for food or fuel. In both, the direction of power is under the influence of an immaterial, thinking, willing principle called the soul. But this must not be confounded,' as it frequently is, with the motive power. The soul of a man no more moves his body than the soul of the engineer moves the locomotive and its attendant train of cars. In both cases the soul is the directing, controlling principle, not the impelling power. Let, for example, a locomotive-engine be placed upon the track, with water in the boiler and fire in the grate—in short, with all the potentials of motion, and it will still remain quiescent. In this state let the engineer enter the tender and touch the valve: the machine instantly becomes instinct with life and volition: it has now a soul to govern its power and direct its operations; and indeed as a whole it may be considered as an enormous animal, of which the wheels and other parts are additions to the body of the engineer.—HENRY *Improvement of the Mechanical Arts, Scientific Writings*, vol. i, p. 312. (Sm. Inst., 1886.)

2006. MACHINERY, PRIMITIVE SUBSTITUTES FOR—*Predecessor of the Suction-pump—Storage of Water by African Women.*—Whether women invented the suction-pump may remain in doubt, but the Bakalahari dames [according to Livingstone], when they wish to draw water, provide twenty or thirty ostrich-egg shells and place them in a net. They tie a bunch of grass to one end of a short reed for a strainer, and insert the apparatus in a hole as deep as the arm will reach, then ram down the wet sand firmly round it. Applying the mouth to the free end of the reed, they draw the water upward by sucking, and discharge it into an ostrich shell, guiding the stream by means of a straw. The whole stock of water passes through the woman's mouth as a pump. The shells are taken home and buried in wet sand for future use —MASON *Woman's Share in Primitive Culture*, ch. 2, p. 25. (A., 1894.)

2007. MAGNET AND AMBER IN CHINA—*A "Breath" Animating Both.*—The earliest reference to [the] attractive property [of amber] is also apparently the first mention of the like property of the magnet and appears in a "Eulogy of the Magnet," written by Kouo pho in 324 A. D., in the following words:

"The magnet draws the iron, and the amber extracts mustard-seeds. There is a breath which penetrates secretly and with velocity, and which communicates itself imperceptibly to that which corresponds to it in the other object. It is an inexplicable thing."

But this is nothing more than a restatement of the European notion of the flow, or virtue, or current, or soul, emanating from the stone or the amber, with which theory the Western civilized world was then familiar, and which, it is safe to say, involves a power of abstract conception which the Chinese mind has never possessed.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 74. (J. W., 1898.)

2008. MAGNET IN GREEK CLASSICS—*Simile of Plato—Transmitted Attraction.*—The first mention of the magnet in the Greek classics is apparently that made in the fragmentary "Œneus" of Euripides, which Suidas quotes, and which distinctly refers to the attraction of the lodestone for the iron. The subject takes definite form, however, in the "Ion" of Plato; and there, in the following words, Socrates describes the famous rings:

"The gift which you have of speaking excellently about Homer is not an art," says the sage, "but, as I was just saying, an inspiration: there is a divinity moving you, like that in the stone which Euripides calls a magnet, but which is commonly known as the stone of Heraclea. For that stone not only attracts iron rings, but also imparts to them similar power of attracting other rings: and sometimes you may see a number of pieces of iron and rings suspended from one another, so as to form quite a long chain; and all of these derive their powers of suspension from the original stone. Now, this is like the muse who first gives to men inspiration herself, and from those inspired, her sons, a chain of other persons is suspended, who will take the inspiration from them."

Plato lived between the years 429 and 348 B. C., and from his time forward the rings of Samothrace are described again and again.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 1, p. 23. (J. W., 1898.)

2009. MAGNET, TEMPORARY OR PERMANENT—*Plasticity of Iron—Coercive*

Force in Steel—Molecular Movement.—There is another kind of magnet, called a permanent magnet, that will remain a magnet after the current is taken away. The permanent magnet is made of steel and hardened; then its poles are placed to the poles of a powerful magnet, either electro or permanent, when its molecular rings are wrenched apart and arranged in a polarized position, as heretofore described. Now take it away from the magnet and it will be found to retain its magnetism. The molecules tend to fly back the same as those of the soft iron, but they cannot because hardened steel is so much finer grained than soft iron, and the molecules are so close together that they are held in position by a friction that is called its coercive force. The soft iron is comparatively free from this coercive force, because its molecules are free to move on each other, so that when they are wrenched out of their natural position they fly back by their own attractions as soon as the force holding them apart is taken away. The molecules of hardened steel are unable to fly back, altho they tend to do it just as much as in the iron, and so it is called a permanent magnet. Its molecules also are under a strain like a bent bow. (The form of such a magnet is usually that of a horseshoe or U.)—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 4, p. 28. (F. H. & H., 1900.)

2010. MAGNITUDE OF MOUND-BUILDER'S WORKS—*Impressive in Vastness and Simplicity.*—The most remarkable group [of North-American mounds] is that near Newark, in the Scioto Valley, which covers an area of four square miles! A plan of these gigantic works is given by Messrs. Squier and Davis, and another, from a later survey, by Mr. Wilson. They consist of an octagon, with an area of fifty, a square occupying twenty acres, and two large circles occupying respectively thirty and twenty acres. From the octagon an avenue formed by parallel walls extends southwards for two miles and a half; there are two other avenues which are rather more than a mile in length, one of them connecting the octagon with the square. . . . The whole area is covered with "gigantic trees of a primitive forest"; and, say Messrs. Squier and Davis, "in entering the ancient avenue for the first time, the visitor does not fail to experience a sensation of awe, such as he might feel in passing the portals of an Egyptian temple or gazing upon the silent ruins of Petra of the Desert."—AVEBURY *Prehistoric Times*, ch. 8, p. 246. (A., 1900.)

2011. MAGNITUDE OF SUN—*Illustrated by Distance from Earth to Moon.*—Since the diameter of the sun is 858,000 miles, there are 429,000 miles from its center to its surface. Now, there are 238,000 miles from here to the moon. If, then, we could place the earth at the center of the sun, like a small kernel in the middle of a colossal fruit, the moon would revolve in the interior of the solar globe, and the distance of the moon would hardly represent more than half the way from the center to the solar surface; to reach this surface from the lunar orbit there would still remain 191,000 miles to pass over!—FLAMMARION *Popular Astronomy*, bk. iii, ch. 2, p. 237. (A.)

2012. MAGNITUDE, REAL AND APPARENT—*First Impressions Do Not Give Deepest Truth.*—In April there shines towards the west a star so far surpassing all others in the heavens in brightness, that it might well be believed to be the most important of all the orbs discernible by us. It is Hesperus, the star of the evening, the planet Venus; and, in reality, so far from being the largest of all the orbs we see, there are but two celestial bodies, besides the moon, which are smaller than this beautiful planet. The planet Jupiter, [tho] . . . far inferior in brightness to Venus, is in reality a globe surpassing her more than thirteen hundred times in volume, . . . while the splendid Sirius, which shines less brightly far than Jupiter, probably surpasses Venus in bulk more than a thousand millions of times.—PROCTOR *Expanse of Heaven*, p. 47. (L. G. & Co., 1897.)

2013. MAMMALIA IN GEOLOGIC TIME—*Elephants in Northern Lands—Mastodon and Dinotherium.*—Mammalian life probably culminated or attained to its maximum in the Miocene and the Early Pliocene periods. Then there were more numerous, larger, and better-developed quadrupeds on our continents than we now find. For example, the elephants, the noblest of the mammals, are at present represented by two species confined to India and parts of Africa. In the Middle Tertiary there were, in addition to the ordinary elephants, two other genera, *Mastodon* and *Dinotherium*, and there were many species which were distributed over the whole northern hemisphere. The sub-Himalayan deposits of India alone have, I believe, afforded seven species, some of them of grander dimensions than either of those now existing. We have no trustworthy evidence as yet that man lived at this period. If he had, he either would have required the protection of a special Eden, or would have needed superhuman strength and sagacity.—DAWSON *Facts and Fancies in Modern Science*, ch. 4, p. 147. (A. B. P. S.)

2014. MAMMALIA OF THE WATERS—*The Whale and Porpoise Not Fishes.*—It is very difficult, for example, to persuade persons ignorant of the principles of anatomy, that the whale and the porpoise are not fish, that they breathe with lungs as man breathes, that they would be drowned if kept long under water, and that, as they suckle their young, they belong to the same great class, *Mammalia*. Living in the same element as fish, and feeding very much as fishes feed, a similar outward form has been given

to them, because that form is the best adapted for progression through the water. But that form has been, so to speak, put on round the mammalian skeleton, and covers all the organs proper to the mammalian class. Whales and porpoises, notwithstanding their form, and their habitat, and their food, are as separate from fishes as the elephant, or the hippopotamus, or the giraffe. —ARGYLL *Reign of Law,* ch. 4, p. 119. (Burt.)

2015. MAMMALIA THE CROWN OF ANIMAL DEVELOPMENT—*Nature's Supreme Purpose to Create the Mother and the Family.*—Ask the zoologist what, judging from science alone, Nature aspired to from the first, he could but answer, *Mammalia*—mothers. In as real a sense as a factory is meant to turn out locomotives or clocks, the machinery of Nature is designed in the last resort to turn out mothers. You will find mothers in lower nature at every stage of imperfection; you will see attempts being made to get at better types; you find old ideas abandoned and higher models coming to the front. And when you get to the top you find the last great act was but to present to the world a physiologically perfect type. It is a fact which no human mother can regard without awe, which no man can realize without a new reverence for woman and a new belief in the higher meaning of Nature, that the goal of the whole plant and animal kingdoms seems to have been the creation of a family, which the very naturalist has had to call *Mammalia.*—DRUMMOND *Ascent of Man,* ch. 8, p. 268. (J. P., 1900.)

2016. MAMMOTH LINKS OLD WORLD WITH NEW—*Giant Organisms Perishable.*—The mammoth, or *Elephas primigenius,* had very extensive geographical range. Its remains are found in North America, but not east of the Rocky Mountains nor south of Columbia River; in the Old Continent, from the farthest extremity of Siberia to the extreme west of Europe, occurring, tho rarely, even in Ireland; it crossed the Alps, and established itself in Italy as far southward as Rome, but it has not yet been discovered in Naples, in any of the Mediterranean islands, or in Scandinavia. In Spain and Denmark it occurs, but is very rare.—AVEBURY *Prehistoric Times,* ch. 9, p. 273. (A., 1900.)

2017. MAN, ADAPTATION OF, TO ERECT POSTURE—*Structure of Manlike Apes Brings Body Down.*—In man the opening at the base of the skull (occipital foramen), through which the spinal cord passes up into the brain, is farther to the front than in the apes, so that his skull, instead of pitching forward, is balanced on the top of the atlas vertebra (so called from Atlas supporting the globe). . . . As he stands upright, the feet serve as bases, enabling the legs to carry the trunk. Thus the erect posture, only imitated with difficult effort by the showman's performing animals, is to man easy and unconstrained. . . . Of the monkey tribes, many walk fairly on all fours as quadrupeds, with legs bent, arms straightened forward, soles and palms touching the ground. But the higher manlike apes are adapted by their structure for a climbing life among the trees, whose branches they grasp with feet and hands. When the orang-utan takes to the ground he shambles clumsily along, generally putting down the outer edge of the feet and the bent knuckles of the hands. The orang and gorilla have the curious habit of resting on their bent fists, so as to draw their bodies forward between their long arms, like a cripple between his crutches. The nearest approach that apes naturally make to the erect attitude is where the gibbon will go along on its feet, touching the ground with its knuckles first on one side and then on the other, or will run some distance with its arms thrown back above its head to keep the balance, or when the gorilla will rise on its legs and rush forward to attack. . . . The apes thus present interesting intermediate stages between quadruped and biped. But only man is so formed that, using his feet to carry him, he has his hands free for their special work.—TYLOR *Anthropology,* ch. 2, p. 40. (A., 1899.)

2018. MAN A MACHINE OF INFINITE DELICACY—*The Rifle Calculable, the Sportsman Incalculable—Human Actions Defy Prediction.*—Altho it is undoubtedly a delicately constructed machine, yet a rifle does not represent the same surpassing delicacy as that, for instance, which characterizes an egg balanced on its longer axis. Even if at full cock, and with a hair-trigger, we may be perfectly certain it will not go off of its own accord. Altho its object is to produce a sudden and violent transmutation of energy, yet this requires to be preceded by the application of an amount of energy, however small, to the trigger, and if this be not spent upon the rifle it will not go off. There is, no doubt, delicacy of construction, but this has not risen to the height of incalculability, and it is only when in the hands of the sportsman that it becomes a machine upon the condition of which we cannot calculate. Now, in making this remark, we define the position of the sportsman himself in the universe of energy. The rifle is delicately constructed, but not surpassingly so; but sportsman and rifle together form a machine of surpassing delicacy, *ergo* the sportsman himself is such a machine. We thus begin to perceive that a human being, or indeed an animal of any kind, is in truth a machine of a delicacy that is practically infinite, the condition or motions of which we are utterly unable to predict. In truth, is there not a transparent absurdity in the very thought that a man may become able to calculate his own movements, or even those of his fellow?—STEWART *Conservation of Energy,* ch. 6, p. 412. (Hum., 1880.)

2019. MAN AND APE—*No Trace of the Missing Link.*—In vain have we sought for the connecting links between man and the apes; the ancestor of man, the real *Proanthropos*, has not been found. Twenty years ago it seemed as if the process of descent from the ape to man could be constructed by storm. Now, however, we cannot even trace the descent of the different races from one another. At this moment we can say that among people of ancient times none have been found who were nearer the apes than we are. I can affirm at present that there is no absolutely unknown race of men on earth. Every living race is human; none has been found which we could either call simian or between the ape and man. So far as the pile structures are concerned, I have been able to examine nearly all the skulls found, and the result is that we find differences between the various tribes, but that not one of these tribes lies outside of the range of still existing people. It can be definitely proved that in the course of five thousand years no change of types worthy of mention has occurred.—VIRCHOW *Address before the Anthropological Congress in Vienna, 1889.* (Translated for *Scientific Side-Lights.*)

2020. ——— ——— *Physical Likeness with Mental Remoteness.*—One of the chief factors in the production of man was the change that occurred in the direction of the working of natural selection, whereby in the line of man's direct ancestry the variations in intelligence came to be seized upon, cherished, and enhanced, to the comparative neglect of variations in bodily structure. The physical differences between man and ape are less important than the physical differences between African and South-American apes. The latter belong to different zoological families, but the former do not. Zoologically, man is simply one genus in the Old-World family of apes. Psychologically, he has traveled so far from apes that the distance is scarcely measurable.—FISKE *Through Nature to God*, pt. i, ch. 9, p. 49. (H. M. & Co., 1900.)

2021. ——— ——— *Unfilled Gap between.*—Even Haeckel admits that there is a wide gap, unfilled by any recent or any fossil creature, between man and the highest apes.—DAWSON *Facts and Fancies in Modern Science*, lect. 4, p. 142. (A. B. P. S.)

2022. MAN AND MIMOSA—*Man Has What Is in Mimosa—Mimosa Has Not What Is in Man.*—To say that self-consciousness has arisen from sensation, and sensation from the function of nutrition, let us say, in the *Mimosa pudica*, or sensitive plant, may be right or wrong; but the error can only be serious when it is held that that accounts either for self-consciousness or for the transition. *Mimosa* can be defined in terms of man; but man cannot be defined in terms of *Mimosa*. The first is possible because there is the least fraction in that which is least in man of that which is greatest in *Mimosa;* the last is impossible because there is nothing in *Mimosa* of that which is greatest in man. . . . Man, in the last resort, has self-consciousness, *Mimosa* sensation, and the difference is qualitative as well as quantitative.—DRUMMOND *Ascent of Man*, ch. 4, p. 126. (J. P., 1900.)

2023. MAN AND WOMAN TAUGHT BY DIFFERENT ANIMAL TEACHERS—In contact with the animal world, and ever taking lessons from them, men watched the tiger, the bear, the fox, the falcon, learned their language and imitated them in ceremonial dances. But women were instructed by the spiders, the nest-builders, the storers of food, and the workers in clay, like the mud-wasp and the termites. It is not meant that these creatures set up schools to teach dull women how to work, but that their quick minds were on the alert for hints coming from these sources. Even tho we disarm our soldiery, we do not seem to be able to dissociate men from the works that bring violent death. It is in the apotheosis of industrialism that woman has borne her part so persistently and well. At the very beginning of human time she laid down the lines of her duties, and she has kept to them unremittingly.—MASON *Woman's Share in Primitive Culture*, ch. 1, p. 2. (A., 1894.)

2024. MAN, ANTIQUITY OF—*Languages Developed in Prehistoric Time.*—The main work of language-making was done in the ages before history. Going back as far as philology can take us, we find already existing a number of language-groups, differing in words and structure, and, if they ever had any relationship with one another, no longer showing it by signs clear enough for our skill to make out. Of an original primitive language of mankind, the most patient research has found no traces. The oldest types of language we can reach by working back from known languages show no signs of being primitive tongues of mankind. Indeed, it may be positively asserted that they are not such, but that ages of growth and decay have mostly obliterated the traces how each particular sound came to express its particular sense. Man, since the historical period, has done little in the way of absolute new creation of language, for the good reason that his wants were already supplied by the words he learnt from his fathers, and all he had to do when a new idea came to him was to work up old words into some new shape. Thus the study of languages gives much the same view of man's antiquity as has been already gained from the study of races. The philologist, asked how long he thinks mankind to have existed, answers that it must have been long enough for human speech to have grown from its earliest beginnings into elaborate languages, and for these in their turn to have developed into families spread far and

wide over the world. This immense work had been already accomplished in ages before the earliest inscriptions of Egypt, Babylon, Assyria, Phenicia, Persia, Greece, for these show the great families of human speech already in full existence.—TYLOR *Anthropology*, ch. 1, p. 12. (A., 1899.)

2025. ——— ——— *Stone Age Coeval with Buried Pine-forests.*—The question is how long ago tribes who made such stone implements were living in Europe. As to this, we may fairly judge from the position in which they are found in Denmark. The forests of that country are mainly of beeches, but in the peat-mosses lie innumerable trunks of oaks, which show that at an earlier period oak forests prevailed, and deeper still there lie trunks of pine-trees, which show that they were pine forests still older than the oak forests. Thus there have been three successive forest-periods, the beech, the oak, and the pine; and the depth of the peat-mosses, which in places is as much as thirty feet, shows that the period of the pine-trees was thousands of years ago. While the forests have been changing, the condition of the people living among them has changed also. The modern woodman cuts down the beech-trees with his iron ax, but among the oak-trunks in the peat are found bronze swords and shield-bosses, which show that the inhabitants of the country were then in the Bronze Age; and, lastly, a flint hatchet taken out from where it lay still lower in the peat beneath the pine-trunks, proves that Stone-Age men in Denmark lived in the pine-forest period, which carries them back to high antiquity. In England the tribes who have left such stone implements were in the land before the invasion of that Celtic race whom we call the ancient Britons, and who no doubt came armed with weapons of metal. The stone hatchet-blades and arrow-heads of the older population lie scattered over our country, hill and dale, moor and fen, near the surface of the ground, or deeper underground in peat-mosses or beds of mud and silt.—TYLOR *Antropology*, ch. 1, p. 26. (A., 1899.)

2026. MAN A PART OF NATURE—*Type of the Supernatural.*—All the analogies of human thought are in themselves analogies of Nature; and in proportion as they are built up or are perceived by mind in its higher attributes and work, they are part and parcel of natural truth. Man—he whom the Greeks call *Anthropos*, because, as it has been supposed, he is the only being whose look is upward—man is a part of Nature, and no artificial definitions can separate him from it. And yet in another sense it is true that man is above Nature—outside of it; and in this aspect he is the very type and image of the "supernatural."—ARGYLL *Unity of Nature*, ch. 8, p. 183. (Burt.)

2027. MAN AS A MEAT-EATER—Helvetius claimed that man was intended to be carnivorous; J. J. Rousseau maintained, on the contrary, that, like the anthropoids and the primates in general, man is herbivorous, and tends to become carnivorous in proportion as he develops. The prehistoric man was herbivorous and frugivorous. Later, the invention of stone instruments fitted him to pursue fishing and the chase. Finally, the domestication of certain animals furnished him with a constant provision of meat. It was thus that from being herbivorous man has become omnivorous. But for a long period meat played only a secondary rôle in the alimentation of the superior races. It is only within the last century that this rôle has increased to such proportions that Europe has become actually more carnivorous than herbivorous. In France, for example, the food, which was almost exclusively vegetable up to a hundred years ago, tends more and more to become animal.—DELAUNAY *Études de Biologie comparées*, 2e *partie*, p. 34. (Translated for *Scientific Side-Lights.*)

2028. MAN AS AN INSTRUMENT OF RESEARCH—*Specialists in German Universities.*—The German universities are proud of the number of young specialists whom they turn out every year, not necessarily men of any original force of intellect, but men so trained to research that when their professor gives them an historical or philological thesis to prepare, or a bit of laboratory work to do, with a general indication as to the best method, they can go off by themselves and use apparatus and consult sources in such a way as to grind out in the requisite number of months some little pepper-corn of new truth worthy of being added to the store of extant human information on that subject. Little else is recognized in Germany as a man's title to academic advancement than his ability thus to show himself an efficient instrument of research.—JAMES *Talks to Teachers*, ch. 4. p. 31. (H. H. & Co., 1900.)

2029. MAN AS A SEED-DISTRIBUTER—*Commerce and Agriculture—Good and Evil Spread Abroad.*—The agency of man in the distribution of plants exceeds in importance that of all other means combined. He buys and sells seeds and plants, and sends them to all parts of the habitable globe. He exterminates many plants in large areas, and substitutes in large measure those of his choice. Mixed with seeds of grasses, clovers, or grains, he introduces many weeds and sows them to grow with his crops.—BEAL *Seed Dispersal*, ch. 8, p. 81. (G. & Co., 1898.)

2030. MAN A UNITY, AS A TREE IS NOT—*Nervous System Makes the Difference.*—If I begin chopping the foot of a tree its branches are unmoved by my act, and its leaves murmur as peacefully as ever in

the wind. If, on the contrary, I do violence to the foot of a fellow man, the rest of his body instantly responds to the aggression by movements of alarm or defense. The reason of this difference is that the man has a nervous system, whilst the tree has none; and the function of the nervous system is to bring each part into harmonious cooperation with every other.—JAMES *Psychology*, vol. i, ch. 1, p. 12. (H. H. & Co., 1899.)

2031. MAN A UNIVERSAL DWELLER ON THE EARTH—*Unity of the Race.*—From the earliest times when civilized men began to explore distant regions, they found everywhere other races of men already established. And this has held true down to the latest acquisitions of discovery. When the New World was discovered by Columbus he found that it must have been a very old world indeed to the human species. Not only every great continent, but, with rare exceptions, even every habitable island has been found peopled by the genus *Homo*. The explorers might find, and in many cases did actually find, everything else in Nature different from the country of their birth. Not a beast, or bird, or plant, not an insect, or a reptile, or a fish, might be the same as those of which they had any previous knowledge. The whole face of Nature might be new and strange—but always with this one solitary exception, that everywhere man was compelled to recognize himself—represented, indeed, often by people of strange aspect and of strange speech, but by people, nevertheless, exhibiting all the unmistakable characters of the human race.—ARGYLL *Unity of Nature*, ch. 10, p. 234. (Burt.)

2032. MAN BEHIND INSTRUMENT—*Great Discoveries with Small Telescopes.*—We know that Galileo made his discoveries of Jupiter's satellites with an instrument that magnified only seven diameters, and that he never could have used one of a higher power than thirty-two. . . .

During the many years I passed at the Paris Observatory I frequently had in my hands the instruments made by Campani, which were in such great repute during the reign of Louis XIV.; and when we consider the faint light of Saturn's satellites, and the difficulty of managing instruments worked by strings only, we cannot sufficiently admire the skill and the untiring perseverance of the observer.—HUMBOLDT *Cosmos*, vol. iii, p. 61. (H., 1897.)

2033. MAN BUILDS CIVILIZATION BY CHANGING THE PLACES OF THINGS—The miner moves the ore and the fuel from their subterranean resting-places, then they are moved into the furnace, and by another moving of combustibles the working of the furnace is started; then the metals are moved to the foundries and forges, then under hammers, or squeezers, or into melting-pots, and thence to molds. The workman shapes the bars, or plates, or castings by removing a part of their substance, and by more and more movings of material produces the engine, which does its work when fuel and water are moved into its fireplace and boiler. The statue is within the rough block of marble; the sculptor merely moves away the outer portions, and thereby renders his artistic conception visible to his fellow men. The agriculturist merely moves the soil in order that it may receive the seed, which he then moves into it, and when the growth is completed he moves the result, and thereby makes his harvest. The same may be said of every other operation. Man alters the position of physical things in such wise that the forces of Nature shall operate upon them, and produce the changes or other results that he requires.—WILLIAMS *Chemistry of Cookery*, ch. 1, p. 1. (A., 1900.)

2034. MAN CAN NEVER APPREHEND FIRST CAUSES—All our knowledge is limited, and we can never apprehend the *first causes* of any phenomena. The force of crystallization, the force of gravitation and chemical affinity remain in themselves just as incomprehensible as adaptation and inheritance or will and consciousness.—HAECKEL *History of Creation*, vol. i, ch. 2, p. 33. (K. P. & Co., 1899.)

2035. MAN CHANGING NATURAL PRODUCTS—*Nature's Changes Slow—Those Wrought by Human Agency Sudden.*—What Nature brings about in a great lapse of time we occasion suddenly by changing the circumstances in which a species has been accustomed to live. All are aware that vegetables taken from their birthplace and cultivated in gardens undergo changes which render them no longer recognizable as the same plants. Many which were naturally hairy become smooth, or nearly so; a great number of such as were creepers and trailed along the ground rear their stalks and grow erect. Others lose their thorns or asperities; others, again, from the ligneous state which their stem possessed in hot climates, where they were indigenous, pass to the herbaceous: and, among them, some which were perennials become mere annuals. So well do botanists know the effects of such changes of circumstances that they are averse to describe species from garden specimens, unless they are sure that they have been cultivated for a very short period.—LYELL *Principles of Geology*, bk. iii, ch. 33, p. 569. (A., 1854.)

2036. MAN, CIVILIZED, BECOMES MASTER OF HIS ENVIRONMENT—The serious mistake made by Buckle is that he thought what is true of man in his savage state is also true of him during all the stages of his development—namely, that man always remains under the dominion of his environment. The truth, however, is that man frees himself from his environment in proportion as he rises in civilization, so that instead of being Nature's slave he becomes its master.—BASTIAN *Remark While Guid-*

ing the Philosophical Society of Berlin through the Ethnographical Museum. (Translated for *Scientific Side-Lights.)*

2037. MAN, CIVILIZED, CONSUMING THE EARTH'S CAPITAL—It seems to me impossible to consider what is actually taking place on the earth at present without perceiving that within periods, short, indeed, by comparison with geological eras, and still shorter compared with the intervals to which the astronomical history of our earth has introduced us. the condition of the earth as an abode of life will be seriously modified by the ways and works of man. . . . Civilized man is not content to take his share of the earth's income—he uses the garnered wealth which is the earth's capital, and this at a rate which is not only ever increasing, but is increasing at an increasing rate. The rapid consumption of coal is but a single instance of his wasteful expenditure of the stores which during countless ages have been gathered together seemingly for the use of man.—PROCTOR *Our Place among Infinities*, p. 25. (L. G. & Co., 1897.)

2038. MAN COMPARED WITH LOWER ANIMALS—*Resemblance and Contrast.*—It is now more than thirty years since Dr. Pritchard, who, perhaps, of all others merits the title of founder of modern anthropology, stated in the following forcible passage, which opens his "Natural History of Man," the closeness of man's physical relation to the lower animals: "The organized world presents no contrasts and resemblances more remarkable than those which we discover on comparing mankind with the inferior tribes. That creatures should exist so nearly approaching to each other in all the particulars of their physical structure, and yet differing so immeasurably in their endowments and capabilities, would be a fact hard to believe if it were not manifest to our observation. The differences are everywhere striking; the resemblances are less obvious in the fulness of their extent, and they are never contemplated without wonder by those who, in the study of anatomy and physiology, are first made aware how near is man in his physical constitution to the brutes. In all the principles of his internal structure. in the composition and functions of his parts, man is but an animal. The lord of the earth, who contemplates the eternal order of the universe, and aspires to communion with its invisible Maker. is a being composed of the same materials, and framed on the same principles, as the creatures which he has tamed to be the servile instruments of his will. or slays for his daily food. The points of resemblance are innumerable; they extend to the most recondite arrangements of that mechanism which maintains instrumentally the physical life of the body. which brings forward its early development, and admits, after a given period, its decay, and by means of which is prepared a succession of similar beings destined to perpetuate the race."—DANIEL WILSON *Anthropology*, ch. 2, p. 2. (Hum., 1885.)

2039. MAN CONSTRUCTS IMAGINARY CHARACTER — *Imagines Himself What He Would Have Men Believe Him.*—It is plain that the external conditions of life impose on the individual certain habits of feeling which often conflict with his personal propensities. As a member of society he has a powerful motive to attribute certain feelings to himself, and this motive acts as a bias in disturbing his vision of what is actually in his mind. While this holds good of lighter matters, as that of enjoyment, it applies still more to graver matters. Thus, for example, a man may easily persuade himself that he feels a proper sentiment of indignation against a perpetrator of some mean or cruel act, when as a matter of fact his feeling is much more one of compassion for the previously liked offender. In this way we impose on ourselves, disguising our real sentiments by a thin veil of make-believe.—SULLY *Illusions*, ch. 8, p. 202. (A., 1897.)

2040. MAN CONTEMPORARY WITH EXTINCT ANIMALS—*The Irish Elk in England and France.*—It must be regarded as a well-ascertained fact that even during the human period the pleasant and sunny valleys of England and of France have been inhabited by the gigantic Irish elk, two species of elephant, and three of rhinoceros, together with the reindeer, a large bear closely resembling the grizzly bear of the Rocky Mountains, a bison scarcely distinguishable from that of the American prairies, the musk-ox of Arctic America, the lemming of the Siberian steppes, the lion of the tropics, the hyena of the Cape, and a hippopotamus closely resembling that of the great African rivers.—AVEBURY *Prehistoric Times*, ch. 9, p. 289. (A., 1900.)

2041. MAN DEVELOPS IN MIND, AS ANIMALS IN BODY—*Increasing Harmony with Environment.*—[That] principle of natural selection which in animals affects the body and seems to have little influence on the mind, in man affects the mind and has little influence on the body. In the first, it tends mainly to the preservation of life; in the second, to the improvement of the mind, and consequently to the increase of happiness. It insures, in the words of Mr. Herbert Spencer, "a constant progress towards a higher degree of skill, intelligence, and self-regulation, a better coordination of actions, a more complete life." . . . The tendency of recent improvements and discoveries is less to effect any rapid change in man himself than to bring him into harmony with Nature; less to confer upon him new powers than to teach him how to apply the old.—AVEBURY *Prehistoric Times*, ch. 16, p. 576. (A., 1900.)

2042. MAN EMPHASIZES NATURE'S VARIATIONS — We cannot suppose that all the breeds were suddenly produced as perfect and as useful as we now see them; indeed, in many cases, we know that this has not been their history. The key is man's power of accumulative selection: Nature gives successive variations; man adds them up in certain directions useful to him. In this sense he may be said to have made for himself useful breeds.—DARWIN *Origin of Species*, ch. 1, p. 26. (Burt.)

2043. MAN, EVIDENCES OF HIS RECENT ORIGIN—*Fossils of Existing Organisms Where Still No Human Trace.*—Thus, for example, in the deposits called the "northern drift," or the glacial formation of Europe and North America, the fossil marine shells can easily be identified with species either now inhabiting the neighboring sea, or living in the seas of higher latitudes. Yet they exhibit no memorials of the human race, or of articles fabricated by the hand of man. Some of the newest of these strata, passing by the name of "raised beaches," occur at moderate elevations on the coast of England, Scotland, and Ireland. Other examples are met with on a more extended scale in Scandinavia, as at the height of 200 feet at Uddevalla in Sweden, and at twice that elevation near Christiania in Norway, also at an altitude of 600 or 700 feet in places farther north. They consist of beds of sand and clay, filling hollows in a district of granite and gneiss, and they must closely resemble the accumulations of shelly matter now in progress at the bottom of the Norwegian fiords. The rate at which the land is now rising in Scandinavia is far too irregular in different places to afford a safe standard for estimating the minimum of time required for the upheaval of the fundamental granite, and its marine shelly covering, to the height of so many hundred feet; but according to the greatest average, of five or six feet in a century, the period required would be very considerable, and nearly the whole of it, as well as the antecedent epoch of submergence, seems to have preceded the introduction of man into these parts of the earth.—LYELL *Principles of Geology*, bk. i, ch. 13, p. 184. (A., 1854.)

2044. MAN, FOSSIL REMAINS OF—*Not an Ape-like Creature—Tools and Implements Show Primeval Man Thoroughly Human.*—In conclusion, I may say that the fossil remains of man hitherto discovered do not seem to me to take us appreciably nearer to that lower pithecoid form by the modification of which he has, probably, become what he is. And considering what is now known of the most ancient races of men; seeing that they fashioned flint axes and flint knives and bone-skewers of much the same pattern as those fabricated by the lowest savages at the present day, and that we have every reason to believe the habits and modes of living of such people to have remained the same from the time of the mammoth and the tichorhine rhinoceros till now, I do not know that this result is other than might be expected.—HUXLEY *Man's Place in Nature*, p. 253. (Hum.)

2045. MAN HAS MYSTERIOUS POWER OVER PUMA—*Even Child Safe with South-American Lion.*—How strange that this most cunning, bold, and bloodthirsty of the *Felidæ* [the puma], the persecutor of the jaguar and the scourge of the ruminants in the regions it inhabits, able to kill its prey with the celerity of a rifle-bullet, never attacks a human being! Even the cowardly, carrion-feeding dog will attack a man when it can do so with impunity: but in places where the puma is the only large beast of prey, it is notorious that it is there perfectly safe for even a small child to go out and sleep on the plain. At the same time it will not fly from man (tho the contrary is always stated in books of natural history) except in places where it is continually persecuted. Nor is this all: it will not, as a rule, even defend itself against man, altho in some rare instances it has been known to do so.—HUDSON *Naturalist in La Plata*, ch. 2, p. 36. (C. & H., 1895.)

2046. MAN HAS SELECTING POWER—*Abstract Conceptions—Self-contemplation.*—There is such a gulf between the faculties of his [man's] mind and those of the lower animals that the forces acting on the human spirit become, by comparison, innumerable, and involve motives belonging to a wholly different class and order. He is exposed, indeed, to the lower motives in common with the beasts. But there are others which operate largely upon him which never can and never do operate upon them. Foremost among these are the motives which man has the power of bringing to bear upon himself, arising out of his power of forming abstract ideas, out of his possession of beliefs, and, above all, out of his sense of right and wrong. So strong are these motives that they are able constantly to overpower, and sometimes almost to destroy, the forces which are related to his lower faculties. Again, among the motives which operate upon him man has a selecting power. He can, as it were, stand out from among them—look down from above them—compare them among each other, and bring them to the test of conscience. Nay, more, he can reason on his own character as he can on the character of another being—estimating his own weakness with reference to this and the other motive, as he is conscious how each may be likely to tell upon him. When he knows that any given motive will be too strong for him, if he allow himself to think of it, he can shut it out from his mind by "keeping the door of his thoughts." He can, and he often does, refuse the thing he sees, and hold by another thing which he cannot see. He may, and he often does, choose the invisible in preference to the

visible. He may, and he often does, walk by faith and not by sight.—ARGYLL *Reign of Law*, ch. 6, p. 182. (Burt.)

2047. MAN, HIS BODY UNDERGOES INCESSANT CHANGE—*Spiritual Identity Constitutes the Personality.*—Science proves that the elements constituting our bodies, even those which seem to have most resistance, are renewing themselves all the while, so that within a given period there is not one molecule but has been transformed; yet in spite of this incessant evolution of atoms there is a being (and that is each one of us) feeling its own identity, remembering what it thought, felt, intended, and performed, ten, twenty, thirty years ago, recognizing itself as the responsible author, accusing or congratulating itself. Without this identity, of which memory is the guardian, there is no longer human personality, nothing but a transient aggregation of molecules remaining united during the space of a human life.—BERSIER *"Souviens Toi" (a Sermon).* (Translated for *Scientific Side-Lights.)*

2048. MAN, HIS DEVELOPMENT DISTINGUISHES HIM FROM OTHER ANIMALS—The attitude of the human being toward Nature is entirely different from that of all other animate creatures upon earth. With difficulty and only with the help of adults does the child learn the use of its members, and he requires a longer time than any animal to acquire skill in the most necessary functions of life. Human knowledge and skill do not develop in all individuals as the blossoms and fruit of plants from the seed: human individuals do not, like the animals of the same species, attain to the same facility. More especially it is the peculiar gifts, the position in society, and the destiny of life affecting individual human beings that produce the greatest differences in the cultivation of their physical and mental powers.—DROBISCH *Darwinismus und Sittenlehre.* (Translated for *Scientific Side-Lights.)*

2049. MAN, HIS INFLUENCE UPON THE EARTH—*Effect of Enclosure of Land—Fertility Waiting for Protection.*—But how important an element enclosure is I plainly saw near Farnham, in Surrey. Here there are extensive heaths, with a few clumps of old Scotch firs on the distant hilltops: within the last ten years large spaces have been enclosed, and self-sown firs are now springing up in multitudes, so close together that all cannot live. When I ascertained that these young trees had not been sown or planted I was so much surprised at their numbers that I went to several points of view, whence I could examine hundreds of acres of the unenclosed heath, and literally I could not see a single Scotch fir except the old planted clumps. But on looking closely between the stems of the heath, I found a multitude of seedlings and little trees which had been perpetually browsed down by the cattle. In one square yard, at a point some hundred yards distant from one of the old clumps, I counted thirty-two little trees; and one of them, with twenty-six rings of growth, had during many years tried to raise its head above the stems of the heath, and had failed. No wonder that, as soon as the land was enclosed, it became thickly clothed with vigorously growing young firs. Yet the heath was so extremely barren and so extensive that no one would ever have imagined that cattle would have so closely and effectually searched it for food.—DARWIN *Origin of Species*, ch. 1, p. 67. (Burt.)

2050. MAN, HIS SUPREME DISTINCTION IN THE ANIMAL WORLD—*Love of and Sacrifice for Truth.*—Man strives after the truth for the sake of truth; he wants to know for the sake of knowing; his impulsion for knowledge, his tendency after light and truth, is so strong that, whether knowledge of the truth is productive of injury or advantage, he strives for it. And even if he foresees that the knowledge he has foreboded and sought after will only excite ridicule, hatred, contempt, and persecution as soon as found and communicated to others, he nevertheless persists until he finds and brings it to light. Have not men suffered severe affliction, not shunning cruel martyrdom, from love of the truth? But where in the entire realm of the animal world do you find any trace of this quality?—GRAUE *Darwinismus und Sittlichkeit (Deutsche Zeit- und Streit-Fragen*, p. 454). (Translated for *Scientific Side-Lights.)*

2051. MAN KINDRED TO THE STARS—*The Human Body Analyzed—Spectroscopic Analysis of Heavenly Bodies.*—In the South Kensington Museum there is, as everybody knows, an immense collection of objects, appealing to all tastes and all classes, and we find there at the same time people belonging to the wealthy and cultivated part of society lingering over the Louis Seize cabinets or the old majolica, and the artisan and his wife studying the statements as to the relative economy of baking-powders, or admiring Tippoo Saib's wooden tiger.

There is one shelf, however, which seems to have some attraction common to all social grades, for its contents appear to be of equal interest to the peer and the costermonger. It is the representation of a man resolved into his chemical elements, or rather an exhibition of the materials of which the human body is composed. There is a definite amount of water, for instance, in our blood and tissues, and there on the shelf are just so many gallons of water in a large vessel. Another jar shows the exact quantity of carbon in us; smaller bottles contain our iron and our phosphorus in just proportion, while others exhibit still other constituents of the body; and the whole reposes on the shelf as if ready for the coming of a new Frankenstein to re-create the

original man and make him walk about again as we do. The little vials that contain the different elements which we all bear about in small proportions are more numerous, and they suggest not merely the complexity of our constitutions, but the identity of our elements with those we have found by the spectroscope, not alone in the sun, but even in the distant stars and nebulæ; for this wonderful instrument of the new astronomy can find the traces of poison in a stomach or analyze a star, and its conclusions lead us to think that the ancients were nearly right when they called man a microcosm, or little universe. We have literally within our own bodies samples of the most important elements of which the great universe without is composed, and you and I are not only like each other, and brothers in humanity, but children of the sun and stars in a literal sense, having bodies actually made in large part of the same things that make Sirius and Aldebaran. They and we are near relatives.—LANGLEY *The New Astronomy*, ch. 8, p. 221. (H. M. & Co., 1896.)

2052. MAN MODIFYING NATURE—*Domestic Animals Remolded to His Will.*—It appears as if any special quality or modification in an animal can be obtained if we only breed it in sufficient quantity, watch carefully for the required variations, and carry on selection with patience and skill for a sufficiently long period. Thus, in sheep we have enormously increased the wool, and have obtained the power of rapidly forming flesh and fat; in cows we have increased the production of milk; in horses we have obtained strength, endurance, or speed, and have greatly modified size, form, and color; in poultry we have secured various colors of plumage, increase of size, and almost perpetual egg-laying.—WALLACE *Darwinism*, ch. 4, p. 63. (Hum.)

2053. MAN, MORAL NATURE OF—*Human Conduct the Subject-matter of the Moral Sense.*—What is the subject-matter of the moral sense? or, in other words, what is the kind of thing of which alone it takes any cognizance, and in which alone it recognizes the qualities of right and wrong?

To this fundamental question one answer, and one answer only, can be given. The things, and the only things, of which the moral sense takes cognizance are the actions of man. It can take no cognizance of the actions of machines, nor of the actions of the inanimate forces of Nature, nor of the actions of beasts, except in so far as a few of these may be supposed to possess in a low and elementary degree some of the characteristic powers of man. Human conduct is the only subject-matter in respect of which the perceptions of the moral sense arise. They are perceptions of the mind which have no relation to anything whatever except to the activities of another mind constituted like itself.—ARGYLL *Unity of Nature*, ch. 9, p. 196. (Burt.)

2054. MAN MORE FEARFUL THAN NATURE—*Spartacus in Vesuvius.*—What was the real condition of Campania during those years of dire convulsion [of Vesuvius]? "A climate where heaven's breath smells sweet and wooingly—a vigorous and luxuriant Nature unparalleled in its productions—a coast which was once the fairy-land of poets and the favorite retreat of great men. Even the tyrants of the creation loved this alluring region, spared it, adorned it, lived in it, died in it." [Forsyth's "Italy," vol. ii.] The inhabitants, indeed, have enjoyed no immunity from the calamities which are the lot of mankind; but the principal evils which they have suffered must be attributed to moral, not to physical, causes—to disastrous events over which man might have exercised a control, rather than to the inevitable catastrophes which result from subterranean agency. When Spartacus encamped his army of ten thousand gladiators in the old extinct crater of Vesuvius, the volcano was more justly a subject of terror to Campania than it has ever been since the rekindling of its fires.—LYELL *Geology*, ch. 24, p. 395. (A., 1854.)

2055. MAN MUST ACQUIRE INSTINCTS—*Habit the Process of Acquisition—Economy of Automatism.*—Man is born with a tendency to do more things than he has ready-made arrangements for in his nerve-centers. Most of the performances of other animals are automatic. But in him the number of them is so enormous that most of them must be the fruit of painful study. If practise did not make perfect, nor habit economize the expense of nervous and muscular energy, he would therefore be in a sorry plight. As Dr. Maudsley says:

"If an act became no easier after being done several times, if the careful direction of consciousness were necessary to its accomplishment on each occasion, it is evident that the whole activity of a lifetime might be confined to one or two deeds—that no progress could take place in development. A man might be occupied all day in dressing and undressing himself; the attitude of his body would absorb all his attention and energy; the washing of his hands or the fastening of a button would be as difficult to him on each occasion as to the child on its first trial; and he would, furthermore, be completely exhausted by his exertions. Think of the pains necessary to teach a child to stand, of the many efforts which it must make, and of the ease with which it at last stands, unconscious of any effort. For while secondarily automatic acts are accomplished with comparatively little weariness—in this regard approaching the organic movements, or the original reflex movements—the conscious effort of the will soon produces exhaustion."—JAMES *Psychology*, vol. i, ch. 4, p. 113. (H. H. & Co., 1899.)

2056. MAN NOT A MERE AUTOMATON—*His Automatic Actions Subordinate and Subsidiary—Each Generation Starts*

Anew.—An apparatus for controlling one of the lower animals can be turned out from the workshop of Nature sometimes in a day. The wheels are few, the works are simple, the connections require little time for adjustment or correction. Everything that a humble organism will do has been done a million times by its parents, and already the faculties have been carefully instructed by heredity and will automatically repeat the whole life and movement of their race. But when a man is made it is not an automaton that is made. This being will do new things, think new thoughts, originate new ways of life. . . . For half the life, therefore, that lies before the human offspring no storage of habit has been handed down from the past. . . . Into the infant's frame must be fitted not only the apparatus for automatic repetition of what its parents have done, but the apparatus for intelligent initiation; not only the machinery for carrying on the involuntary and reflex actions—involuntary and reflex because they have been done so often by its ancestors as to have become automatic—but for the voluntary and self-conscious life which will do new things, choose fresh alternatives, seek higher and more varied ends. The instrument which will attend to breathing even when we forget it; the apparatus which will make the heart beat even tho we try to stop it; the self-acting spring which makes the eyelid close the moment it is threatened—these and a hundred others are old and well-tried inventions which, from ceaseless practise generation after generation, work perfectly in each new individual from the start. . . . But the higher brain is comparatively a new thing in the world. It has to undertake a vaster range of duties, often totally new orders of duties; it has to do things which its forerunners had not quite learned to do, or had not quite learned to do unthinkingly, and the inconceivably complex machinery requires time to settle to its work.—DRUMMOND *Ascent of Man*, ch. 8, p. 283. (J. P., 1900.)

2057. MAN NOT PERFECT, BUT PERFECTIBLE—For the creation of man was by no means the creation of a perfect being. The most essential feature of man is his improvableness.—FISKE *Destiny of Man*, ch. 10, p. 71. (H. M. & Co., 1900.)

2058. MAN, PRIMEVAL—*Not Like Modern Degraded Races—Fuegians and Tasmanians Not Types—Brain Power of Earliest Men.*—Thus it would appear that these earliest known men are not specifically distinct from ourselves, but are a distinct race, most nearly allied to that great Turanian stock which is at the present day, and has apparently from the earliest historic times been, the most widely spread of all. Tho rude and uncultured, they were not either physically or mentally inferior to the average men of to-day, and were indeed in several respects men of high type, whose great cranial capacity might lead us to suppose that their ancestors had recently been in a higher state of civilization than themselves. It is, however, possible that this characteristic was rather connected with great energy and physical development than with high mental activity.

To the hypothesis of evolution, as applied to man, these facts evidently oppose great difficulties. They show that such modern degraded races as the Fuegians or the Tasmanians cannot present to us the types of our earlier ancestors, since the latter were men of a different and higher style. Nor do these oldest known men present any approximation in physical characters to the lower animals. Further, we may infer from their works, and from what we know of their beliefs and habits, that they were not creatures of instinct, but of thought like ourselves, and that materialistic doctrines of automatism and brain force without mind would be quite as absurd in their application to them as to their modern representatives.—DAWSON *Facts and Fancies in Modern Science*, ch. 4, p. 172. (A. B. P. S.)

2059. ——— ——— *The Embodiment of Helplessness and Homelessness.*—Go with me to that early day when the first being worthy to be called man stood upon this earth. How economical has been his endowment. There is no hair on his body to keep him warm, his jaws are the feeblest in the world, his arm is not equal to that of a gorilla, he cannot fly like the eagle, he cannot see into the night like the owl, even the hare is fleeter than he. He has no clothing, no shelter. "Foxes had holes, and the birds of the air had nests, but this man had not where to lay his head." He had no tools or industries or experience, no society or language or arts of pleasure; he had yet no theory of life and poorer conceptions of the life beyond. All Nature laughed at him. The sun said, I will blister his skin. The storm said, I will spit upon him. The sea said, I will drown him. The noxious malaria said, I will parch him with fevers. The lion, the wolf, the tiger said, I will devour him. The mountain-sheep withheld her fleece and lambs. The wild ass and the wild horse fled away in scorn. The silly fish said, I know you not, and the birds skimmed the air around him in mockery. There were no waving grain fields, nor golden corn fields, nor tempting vineyards, nor fragrant orchards.

"Poor naked wretches, on the edge of time,
That bide the pelting of this pitiless storm,
How shall your houseless heads and unfed sides defend you
From seasons such as these?"
King Lear, iii, 1.

Whatever we may say of our own golden age, surely his was not around him nor above him. If he had one at all it was within him.—MASON *The Birth of Invention*

(Address at Centenary of the American Patent System, Washington, D. C., 1891; Proceedings of the Congress, p. 404.)

2060. ——— ——— *The Neanderthal Skull Thoroughly Human—No Link between Man and Ape.*—Under whatever aspect we view this [Neanderthal] cranium, whether we regard its vertical depression, the enormous thickness of its supraciliary ridges, its sloping occiput, or its long and straight squamosal suture, we meet with ape-like characters, stamping it as the most pithecoid of human crania yet discovered. But Professor Schaaffhausen states that the cranium, in its present condition, holds 1,033.24 cubic centimeters of water, or about 63 cubic inches, and as the entire skull could hardly have held less than an additional 12 cubic inches, its capacity may be estimated at about 75 cubic inches, which is the average capacity given by Morton for Polynesian and Hottentot skulls.

So large a mass of brain as this would alone suggest that the pithecoid tendencies, indicated by this skull, did not extend deep into the organization; and this conclusion is borne out by the dimensions of the other bones of the skeleton given by Professor Schaaffhausen, which show that the absolute height and relative proportions of the limbs were quite those of an European of middle stature. The bones are indeed stouter, but this and the great development of the muscular ridges noted by Dr. Schaaffhausen are characters to be expected in savages. The Patagonians, exposed without shelter or protection to a climate possibly not very dissimilar from that of Europe at the time during which the Neanderthal man lived, are remarkable for the stoutness of their limb bones.

In no sense, then, can the Neanderthal bones be regarded as the remains of a human being intermediate between men and apes. At most, they demonstrate the existence of a man whose skull may be said to revert somewhat toward the pithecoid type. —HUXLEY *Man's Place in Nature*, p. 253. (Hum.)

2061. MAN, PRIMITIVE—*Adopts Ornament before Clothing.*—Man has been defined as the animal that is fond of finery. Before he manifests any care for clothing, unless compelled by the inclemency of his climate, he thinks of his ornament.—BASTIAN *Allgemeine Grundzüge der Ethnologie*, p. 24. (Translated for *Scientific Side-Lights.*)

2062. ——— ——— *Camel the Inseparable Companion of—The One Great Essential of Patriarchal Life—Long Historic Record of an Animal—"Ship of the Desert."*—In the poetry of the East, the camel is designated as the land ship, or the ship of the desert *(Sefynet-el-badyet)*. The camel is, however, not only the carrier in the desert, and the medium for maintaining communication between different countries, but is also, as Carl Ritter has shown ["Asien," § 610, ... "the main requirement of a nomadic mode of life in the patriarchal stage of national development, in the torrid regions of our planet, where rain is either wholly or in a great degree absent. No animal's life is so closely associated by natural bonds with a certain primitive stage of the development of the life of man as that of the camel among the Bedouin tribes, nor has any other been established in like manner by a continuous historical evidence of several thousand years."—HUMBOLDT *Views of Nature*, p. 51. (Bell, 1896.)

2063. ——— ——— *Fancy Sketch of—What Remains Indicate.*—Carrying our imagination back into the past, we see before us on the low shores of the Danish Archipelago a race of small men, with heavy overhanging brows, round heads, and faces probably much like those of the present Laplanders. As they must evidently have had some protection from the weather, it is most probable that they lived in tents made of skins. The total absence of metal in the Kjökkenmöddings [kitchen-middens] indicates that they had not yet any weapons except those made of wood, stone, horn, and bone. Their principal food must have consisted of shell-fish, but they were able to catch fish, and often varied their diet by game caught in hunting. It is evident that marrow was considered a great delicacy, for every single bone which contained any was split open in the manner best adapted to extract the precious morsel. —AVEBURY *Prehistoric Times*, ch. 7, p. 229. (A., 1900.)

2064. ——— ——— *Incapable of Abstract Conceptions—The Infinite—The Invisible—Personality Nearer and Simpler as Well.*—Those who approach the subject with the assumption that the idea of a divine Being or a superhuman personality must be a derivative, and cannot be a primary conception, allow all their language to be colored by the theory that vague perceptions of "The Invisible" or "The Infinite" in rivers, or in mountains, or in sun and moon and stars, were the earliest religious conceptions of the human mind. But this theory cannot be accepted by those who remember that there is nothing in Nature so near to us as our own nature—nothing so mysterious and yet so intelligible—nothing so invisible, yet so suggestive of energy and of power over things that can be seen. Nothing else in Nature speaks to us so constantly or so directly. Neither the infinite nor the invisible contains any religious element at all, unless as conditions of a being of which invisibility and infinitude are attributes. There is no probability that any abstract conceptions whatever about the nature or properties of material force can have been among the earliest conceptions of the human mind. Still less is it reasonable to suppose that such conceptions were more natural and

more easy conceptions than those founded on our own personality and on the personality of parents.—ARGYLL *Unity of Nature*, ch. 12. p. 300. (Burt.)

2065. ——— ——— *Remains Showing His Daily Domestic Life—The Kitchens of the Stone Age.*—The discovery of rude flint implements, and of bones still bearing the marks of knives, confirmed the suppositlon that these beds [the Kjökkenmöddings, kitchen-middens, or shell-mounds of Denmark] were not natural formations, and it subsequently became evident that they were, in fact, the sites of ancient villages: the primitive population having lived on the shore and fed principally on shell-fish, but partly also on the proceeds of the chase. In many places hearths were discovered consisting of flat stones, arranged in such a manner as to form small platforms, and bearing all the marks of fire. The shells and bones not available for food gradually accumulated round the tents and huts, until they formed deposits generally from three to five feet, but sometimes as much as ten feet in thickness, and in some cases more than three hundred yards in length, with a breadth of from one hundred to two hundred feet.—AVEBURY *Prehistoric Times*, ch. 7. p. 215. (A., 1900.)

2066. MAN, RECENT ORIGIN OF— *His Exposure to Special Dangers—Enduring Memorials of His Existence.*—No inhabitant of the land exposes himself to so many dangers on the waters as man, whether in a savage or a civilized state; and there is no animal, therefore, whose skeleton is so liable to become embedded in lacustrine or submarine deposits; nor can it be said that his remains are more perishable than those of other animals; for in ancient fields of battle, as Cuvier has observed, the bones of men have suffered as little decomposition as those of horses which were buried in the same grave. But even if the more solid parts of our species had disappeared, the impression of their form would have remained engraven on the rocks, as have the traces of the tenderest leaves of plants, and the soft integuments of many animals. Works of art, moreover, composed of the most indestructible materials, would have outlasted almost all the organic contents of sedimentary rocks. Edifices, and even entire cities, have, within the times of history, been buried under volcanic ejections, submerged beneath the sea, or engulfed by earthquakes; and had these catastrophes been repeated throughout an indefinite lapse of ages, the high antiquity of man would have been inscribed in far more legible characters on the framework of the globe than are the forms of the ancient vegetation which once covered the islands of the northern ocean, or of those gigantic reptiles which at still later periods peopled the seas and rivers of the northern hemisphere.

. . . .

But so far as our interpretation of physical movements has yet gone, we have every reason to infer that the human race is extremely modern, even when compared to the larger number of species now our contemporaries on the earth.—LYELL *Principles of Geology*, bk. i, ch. 9, pp. 147-48. (A., 1854.)

2067. MAN TESTS RESULTS OF OBSERVATION — *Knows Nature To Be a Whole.*—Nature considered rationally—that is to say, submitted to the process of thought—is a unity in diversity of phenomena; a harmony, blending together all created things, however dissimilar in form and attributes; one great whole (τὸ πᾶν) animated by the breath of life. The most important result of a rational inquiry into nature is, therefore, to establish the unity and harmony of this stupendous mass of force and matter, to determine with impartial justice what is due to the discoveries of the past and to those of the present, and to analyze the individual parts of natural phenomena without succumbing beneath the weight of the whole. Thus and thus alone is it permitted to man, while mindful of the high destiny of his race, to comprehend Nature, to lift the veil that shrouds her phenomena, and, as it were, submit the results of observation to the test of reason and of intellect.—HUMBOLDT *Cosmos*, vol. i, int., p. 24. (H., 1897.)

2068. MAN THE CROWN OF EVOLUTION—*Not To Be Surpassed, but Perfected.*—Who can fail to see that the selection of psychical variations, to the comparative neglect of physical variations, was the opening of a new and greater act in the drama of creation? Since that new departure the Creator's highest work has consisted not in bringing forth new types of body, but in expanding and perfecting the psychical attributes of the one creature in whose life those attributes have begun to acquire predominance. Along this human line of ascent there is no occasion for any further genesis of species; all future progress must continue to be not zoological, but psychological; organic evolution gives place to civilization. Thus in the long series of organic beings man is the last; the cosmic process, having once evolved this masterpiece, could thenceforth do nothing better than to perfect him.—FISKE *Through Nature to God*, pt. ii, ch. 5, p. 84. (H. M. & Co., 1900.)

2069. MAN, THE DESCENT OF—Man might just as well have descended from the sheep or the elephant as from the ape. —VIRCHOW *Address before the Anthropological Congress in Vienna.* (Translated for *Scientific Side-Lights.*)

2070. MAN THE HIGHEST BEING POSSIBLE UNDER EARTHLY CONDITIONS—*Completes Design of Animal Kingdom.* —To me the animal kingdom appears not in indefinite growth like a tree, but a temple with many minarets, none of them capable of being prolonged, while the central

dome is completed by the structure of man. The development of the animal kingdom is the development of intelligence chained to matter; the animals in which the nervous system has reached the greatest perfection are the vertebrates, and in man that part of the nervous system which is the organ of intelligence reaches, as I have sought to show, the highest development possible to a vertebrate animal, while intelligence has grown to reflection and volition. On these grounds, I believe, not that man is the highest possible intelligence, but that the human body is the highest form of human life possible, subject to the conditions of matter on the surface of the globe, and that the structure completes the design of the animal kingdom.—CLELAND, quoted by DRUMMOND in *Ascent of Man*, ch. 3, p. 113. (J. P., 1900.)

2071. MAN TRANSFORMS THE EARTH—*Makes New Environment.*—The destinies of all other living things are more and more dependent upon the will of man. It rests with him to determine, to a great degree, what plants and animals shall remain upon the earth and what shall be swept from its surface. By unconsciously imitating the selective processes of Nature he long ago wrought many wild species into forms subservient to his needs. He has created new varieties of fruit and flower and cereal grass, and has reared new breeds of animals to aid him in the work of civilization, until at length he is beginning to acquire a mastery over mechanical and molecular and chemical forces which is doubtless destined in the future to achieve marvelous results whereof to-day we little dream. Natural selection itself will by and by occupy a subordinate place in comparison with selection by man, whose appearance on the earth is thus seen more clearly than ever to have opened an entirely new chapter in the mysterious history of creation.—FISKE *Destiny of Man*, ch. 3, p. 33. (H. M. & Co., 1900.)

2072. MAN UNITED BY BODILY CONSTITUTION WITH ALL ANIMAL AND VEGETABLE LIFE—*"Of the Dust of the Ground" (Gen. ii, 7).*—Man is included in the unity of Nature, in the first place, as regards the composition of his body. Out of the ordinary elements of the material world is that body made, and into those elements it is resolved again. With all its beauties of form and of expression, with all its marvels of structure and of function, there is nothing whatever in it except some few of the elementary substances which are common in the atmosphere and the soil. The three commonest gases, oxygen, hydrogen, and nitrogen, with carbon and with sulfur, are the foundation-stones. In slightly different proportions these elements constitute the primordial combination of matter which is the abode of life. In the finished structure there appear, besides, lime, potash, and a little iron, sodium, and phosphorus. These are the constituents of the human body—of these in different combinations [it consists]—and, so far as we know, of nothing else. The same general composition, with here and there an ingredient less or more, prevails throughout the whole animal and vegetable world, and its elements are the commonest in the inorganic kingdom also.—ARGYLL *Unity of Nature*, ch. 2, p. 28. (Burt.)

2073. MAN WITHOUT AGRICULTURE — *Shell-mound Builders — Spirituous Liquors Unknown.*—If the absence of cereal remains justifies us, as it appears to do, in concluding that they [the shell-mound builders] had no knowledge of agriculture, they must certainly have sometimes suffered from periods of great scarcity, indications of which may, perhaps, be seen in the bones of the fox, wolf, and other carnivora, which would hardly have been eaten from choice; on the other hand, they were blessed in the ignorance of spirituous liquors, and saved thereby from what is at present the greatest scourge of Northern Europe.—AVEBURY *Prehistoric Times*, ch. 7, p. 231. (A., 1900.)

2074. MAN'S CONSCIOUSNESS OF POWER—*Similar Results in Nature Referred to Supreme Conscious Power.*—We are conscious of the exertion of a power when we either produce or resist motion; whenever, therefore, we see bodies in motion we infer that only by a like exertion of power could that motion have originated: so when the retardation of motion gives rise to heat, or heat (in ceasing to manifest itself as such) gives rise to expansive force, we perceive that it is only the manifestation that is changed, the fundamental power remaining the same. And as we are thus led by the "correlation" doctrine to consider the various agencies of Nature as the expression of a conscious will, we find the highest science completely according with the highest religion, in directing us to recognize the omnipresent and constantly sustaining energy of a personal Deity in every phenomenon of the universe around us, the pantheistic and anthropomorphic conceptions of his character being thus brought into harmony when we view "Nature" as the embodiment of the divine volition, the "forces of Nature" as so many diversified modes of its manifestation, and the "laws of Nature" as nothing but man's expressions of the uniformities which his limited observation can discern in its phenomena.—CARPENTER *Nature and Man*, lect. 5, p. 183. (A., 1889.)

2075. MAN'S EAGERNESS TO KNOW—*Paralysis of Investigation for a Thousand Years—Modern Scientific Revival.*—Our present mastery over the laws and phenomena of light has its origin in the desire of man to know. We have seen the ancients busy with this problem, but, like a child who uses his arms aimlessly, for want of the

necessary muscular exercise, so these early men speculated vaguely and confusedly regarding natural phenomena, not having had the discipline needed to give clearness to their insight and firmness to their grasp of principles. They assured themselves of the rectilinear propagation of light, and that the angle of incidence was equal to the angle of reflection. For more than a thousand years —I might say, indeed, for more than fifteen hundred years subsequently—the scientific intellect appears as if smitten with paralysis, the fact being that during this time the mental force, which might have run in the direction of science, was diverted into other directions.

The course of investigation, as regards light, was resumed in 1100 by an Arabian philosopher named Alhazan. Then it was taken up in succession by Roger Bacon, Vitellio, and Kepler. These men, tho failing to detect the principle which ruled the facts, kept the fire of investigation constantly burning. Then came the fundamental discovery of Snell, that corner-stone of optics, and immediately afterwards we have the application by Descartes of Snell's discovery to the explanation of the rainbow. Following this we have the overthrow, by Römer, of the notion of Descartes that light was transmitted instantaneously through space. Then came Newton's crowning experiments on the analysis and synthesis of white light, by which it was proved to be compounded of various kinds of light of different degrees of refrangibility.—TYNDALL *Lectures on Light*, p. 209. (A., 1898.)

2076. MAN'S LIKENESS TO LOWER ORGANISMS SPRINGS FROM SOME DEEP NECESSITY—Whether man has been separately created out of the inorganic elements of which his body is composed, or whether it was born of matter previously organized in lower forms, this community of structure must equally indicate a corresponding community of relations with external things, and some antecedent necessity deeply seated in the very nature of those things, why his bodily frame should be like to theirs.—ARGYLL *Unity of Nature*, ch. 2, p. 32. (Burt.)

2077. MAN'S ORIGINAL HOME—*A Garden of Eden—Rejection and Degeneracy.*—In the nature of things the original settlements of man must of necessity have been the most highly favored in the conditions he requires. If, on the commonly received theory of development, those conditions produced him, they must have reached, at the time when and in the place where he arose, the very highest degree of perfect adaptation. He must have been happy in the circumstances in which he found himself placed, and presumably he must have been contented to remain there. Equally on the theory of man being a special creation, we must suppose that when weakest and most ignorant he must have been placed in what was to him a garden—that is to say, in some region where the fruits of the earth were abundant and easily accessible. Whether this region were wide or narrow, he would not naturally leave it except from necessity. On every possible supposition, therefore, as to the origin of man, those who in the dispersion of the race were first subjected to hard and unfavorable conditions would naturally be those who had least strength to meet them, and upon whom they would have accordingly the most depressing effect. This is a process of natural rejection which is the inseparable correlative of the process of natural selection. It tends to development in a wrong direction by the combined action of two different circumstances which are inherent in the nature of the case. First, it must be always the weaker men who are driven out from comfortable homes; and, secondly, it must be always to comparatively unfavorable regions that they are compelled to fly. Under the operation of causes so combined as these it would be strange, indeed, if the physical and mental condition of the tribes which have been exposed to them should remain unchanged. —ARGYLL *Unity of Nature*, ch. 10, p. 250. (Burt.)

2078. MAN'S SOCIAL SELF—*Torture of Ostracism.*—A man's social self is the recognition which he gets from his mates. We are not only gregarious animals, liking to be in sight of our fellows, but we have an innate propensity to get ourselves noticed, and noticed favorably, by our kind. No more fiendish punishment could be devised, were such a thing physically possible, than that one should be turned loose in society and remain absolutely unnoticed by all the members thereof. If no one turned round when we entered, answered when we spoke, or minded what we did, but if every person we met "cut us dead," and acted as if we were non-existing things, a kind of rage and impotent despair would ere long well up in us, from which the cruelest bodily tortures would be a relief; for these would make us feel that, however bad might be our plight, we had not sunk to such a depth as to be unworthy of attention at all.—JAMES *Psychology*, vol. i, ch. 10, p. 293. (H. H. & Co., 1899.)

2079. MAN'S WORLD-WIDE UNITY—*Makes the Entire Earth His Province.*—There is only one species of the genus man: and all people of every time and every clime with which we are acquainted might have originated from one common stock. His residence and his diet are both unrestricted: he inhabits the whole habitable earth and feeds upon the varied materials derived from organized creation. Relatively to his moderate bulk, and in comparison with other mammifera, he attains a very advanced age. —BLUMENBACH *Manual of Natural History*, p. 35. (Translated for *Scientific Side-Lights.*)

2080. MANIA, THE COLLECTING—*Miser a Victim of This Blind Impulse—The Same Seen in Lower Animals—A Wood-rat's Collection.*—Every one collects money, and when a man of petty ways is smitten with the collecting mania for this object he necessarily becomes a miser. . . . The hoarding instinct prevails widely among animals as well as among men. Professor Silliman has thus described one of the hoards of the California wood-rat, made in an empty stove of an unoccupied house: "I found the outside to be composed entirely of spikes, all laid with symmetry, so as to present the points of the nails outward. In the center of this mass was the nest, composed of finely divided fibers of hemp packing. Interlaced with the spikes were the following: about two dozen knives, forks, and spoons: all the butchers' knives, three in number: a large carving-knife, fork, and steel; several large plugs of tobacco, . . . an old purse containing some silver, matches, and tobacco; nearly all the small tools from the tool-closets, with several large augers, . . . all of which must have been transported some distance, as they were originally stored in different parts of the house. . . . The outside casing of a silver watch was disposed of in one part of the pile, the glass of the same watch in another, and the works in still another."—JAMES *Psychology*, vol. ii, ch. 24, p. 424. (H. H. & Co., 1890.)

2081. MANUFACTURE OF NUTRITION—*The Struggle for Food To Be Reduced to a Minimum.*—At the present moment chemistry is devoting itself to the experiment of manufacturing nutrition, and with an enthusiasm which only immediate hope begets. It is not the visionaries who have dared to prophesy here. In a hundred laboratories the problem is being practically worked out, and, as one of the highest authorities assures us, "The time is not far distant when the artificial preparation of articles of food will be accomplished." [Remsen, *McClure's Magazine*, January, 1894.] Already, through the labors of other sciences, the struggle for food has been made infinitely easier than it was; but when the immediate quest succeeds, and the food of man is made direct from the elements, the struggle in all its coarser forms will practically be abolished. Civilization cannot ease the whole burden at once; the struggle for life will go on, but it will be the struggle with its fangs drawn.—DRUMMOND *Ascent of Man*, ch. 6, p. 213. (J. P., 1900.)

2082. MANUFACTURES CONDUCTED BY PRIMITIVE WOMAN—Her shop was ample enough, for it was the vaulted sky; but her tools and materials and methods were of the simplest kind. What we do in hours she accomplished in years. But if you could from some exalted position take in the exploitation of the earth and sea, the transformation of raw material into things of use, the transportation of these products in all directions, the commercial transactions involved in the sale of these commodities, you would be astonished to know how many of these wheels were set a-going by women in prehistoric times.—MASON *Woman's Share in Primitive Culture*, ch. 1, p. 4. (A., 1894.)

2083. MARCH OF INSECT ARMIES—*The Leaf-bearing Ants.*—No one can see without astonishment one of these ant armies traveling along the road they have worn so neatly for themselves, those who are coming from the trees looking like a green procession, almost hidden by the fragments of leaves they carry on their backs, while the returning troops, who have already deposited their burden, are hurrying back for more. There seems to be another set of individuals running to and fro, whose office is not quite so clear, unless it be to marshal the whole swarm and act as a kind of police. This view is confirmed by an anecdote related by an American resident here, who told us that he once saw an ant, returning without his load to the house, stopped by one of these anomalous individuals, severely chastised, and sent back to the tree apparently to do his appointed task.—AGASSIZ *Journey in Brazil*, ch. 3, p. 105. (H. M. & Co., 1896.)

2084. MARINER'S COMPASS, FIRST RECORD OF—Now follows in this old treatise of an English monk [Neckham, 1157-1217] probably the first of all known descriptions of the mariner's compass. Here it is:

"The sailors, moreover, as they sail over the sea, when in cloudy weather they can no longer profit by the light of the sun, or when the world is wrapped in the darkness of the shades of night, and they are ignorant to what part of the horizon the prow is directed, place the needle over the magnet, which is whirled round in a circle, until, when the motion ceases, the point of it (the needle) looks to north."

The paragraph from the "De Utensilibus" may be best considered simultaneously with the foregoing. The Latin words present many obscurities, to which it is needless to refer in detail here, since they are considered in the following translation:

"If, then, one wishes a ship well provided with all things, one must have also a needle mounted on a dart. The needle will be oscillated and turn until the point of the needle directs itself to the east (north), thus making known to the sailors the route which they should hold while the Little Bear is concealed from them by the vicissitudes of the atmosphere; for it never disappears under the horizon because of the smallness of the circle which it describes."—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 5, p. 128. (J. W., 1898.)

2085. ——— ——— *Probability that Occident Led Orient—A Chinese Copy.*—The presence of the compass in the early Euro-

pean fleets, manned by natural and instinctive seafarers, can be reasonably accounted for, . . . while the presence of the compass on the contemporary Chinese junks, manned by people having no inborn inclination for the sea, is a circumstance seemingly destitute of ancestry.

The identity of construction of the two instruments, European and Chinese, renders inevitable the presumption that one is an imitation of the other. As between people whose skill lies in originating and people whose skill lies in the wonderful minuteness and accuracy of their copies, few, I imagine, will hesitate in deciding which was probably the reproducer; or fail to reach a reasonable conviction that the mariner's compass of the East is literally a "Chinese copy" of the instrument which led, not the indolent Asiatic, but the daring mariners of England and Spain and Portugal and Italy to the most magnificent achievements of the human race.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 85. (J. W., 1898.)

2086. MARINERS PERPLEXED BY MYSTERIOUS LIGHT—*A Limited Aurora.*—The following case is thus described by Arago ("Œuvres complètes," vol. iv, p. 146): "Major Sabine and Captain J. Ross were returning in the autumn from their first arctic expedition they were still in the Greenland seas, during one of the dark nights of those regions, when they were summoned to the bridge by the officer of the watch, who had just seen something very strange. This was, ahead of the vessel and precisely on their course, a stationary light, which rose to a great height from the surface of the sea, while in all other directions the sky and horizon appeared black as pitch. There was no known danger in those regions, and the direction of the vessel was therefore not changed. When the vessel entered the circle of light the whole crew was silent, attentive, on the alert. The highest parts of the masts and sails could then be seen and all the rigging. The meteor appeared to extend for about four hundred yards. When the stern of the vessel left it it was again in darkness; there was no gradual decline in the intensity of the light. The luminous region could be seen from the stern of the ship for a long time."—ANGOT *Aurora Borealis*, ch. 2, p. 19. (A., 1897.)

2087. MARKINGS OF ANIMALS—*Colors Serving for Recognition—Bird-colors that Are Visible Only in Flight.*—Recognition marks during flight are very important for all birds which congregate in flocks or which migrate together; and it is essential that, while being as conspicuous as possible, the marks shall not interfere with the general protective tints of the species when at rest. Hence they usually consist of well-contrasted markings on the wings and tail, which are concealed during repose, but become fully visible when the bird takes flight.—WALLACE *Darwinism*, ch. 8, p. 151. (Hum.)

2088. ——— ——— *Stripes and Spots Serve for Concealment in Jungle and Forest.*—An experienced tiger-hunter, Major Walford, states in a letter that the haunts of the tiger are invariably full of the long grass, dry and pale yellow, for at least nine months of the year, which covers the ground wherever there is water in the rainy season, and he adds: "I once, while following up a wounded tiger, failed for at least a minute to see him under a tree in grass at a distance of about twenty yards—jungle open—but the natives saw him, and I eventually made him out well enough to shoot him, but even then I could not see at what part of him I was aiming. There can be no doubt whatever that the color of both the tiger and the panther renders them almost invisible, especially in a strong blaze of light, when among grass, and one does not seem to notice stripes or spots till they are dead." It is the black shadows of the vegetation that assimilate with the black stripes of the tiger; and, in like manner, the spotty shadows of leaves in the forest so harmonize with the spots of ocelots, jaguars, tiger-cats, and spotted deer as to afford them a very perfect concealment.—WALLACE *Darwinism*, ch. 8, p. 136. (Hum.)

2089. MARTYRS OF SCIENCE—*Bacon Packing Fowl with Snow—Discovery of the Refrigerating Process.*—The great apostle of experimental philosophy was destined to be its martyr. It had occurred to him that snow might be used with advantage for the purpose of preventing animal substances from putrefying. On a very cold day, early in the spring of the year 1626, he alighted from his coach near Highgate, in order to try the experiment. He went into a cottage, bought a fowl, and with his own hands stuffed it with snow. While thus engaged he felt a sudden chill, and was soon so much indisposed that it was impossible for him to return to Gray's Inn. The Earl of Arundel, with whom he was well acquainted, had a house at Highgate. To that house Bacon was carried. The earl was absent, but the servants who were in charge of the place showed great respect and attention to the illustrious guest. Here, after an illness of about a week, he expired early on the morning of Easter day, 1626. His mind appears to have retained its strength and liveliness to the end. He did not forget the fowl which had caused his death. In the last letter that he ever wrote, with fingers which, as he said, could not steadily hold a pen, he did not omit to mention that the experiment of the snow had succeeded "excellently well."—MACAULAY *Essays, Lord Bacon*, p. 270. (A., 1876.)

2090. ——— ——— *Prudence Must Guide Study—Volcanoes Best Investigated*

in Their Mildest Moods.—At the first recorded eruption of Vesuvius the elder Pliny lost his life in an attempt to approach the mountain and examine the action which was taking place there; and during the last great outburst of the same volcano a band of Neapolitan students, whose curiosity was greater than their prudence, shared the same fate.

But in both these cases the inquirers paid the penalty of having adopted a wrong method. If we wish to examine the mode of working of a complicated steam-engine, it will be of little avail for us to watch the machinery when the full blast of steam is turned on, and the rapid movements of levers, pinions, and slides baffle all attempts to follow them, and render hopeless every effort to trace their connection with one another. But if some friendly hand turn off the greater part of the steam-supply, then, as the rods move slowly backwards and forwards, as the wheels make their measured revolutions, and the valves are seen gradually opening and shutting, we may have an opportunity of determining the relations of the several parts of the machine to one another, and of arriving at just conclusions concerning the plan on which it is constructed.—JUDD *Volcanoes*, ch. 2, p. 7. (A., 1899.)

2091. MARVELOUS, THE, TRANSFORMED—*Newton's Discovery of the Laws of the Cometary Motions.*—In order to upset the theory of prodigies it was necessary to find the laws of the motion of comets. This is what Newton did in the case of the comet of 1680. Having ascertained that, according to the laws of universal gravitation, the path of the comet should be a very elongated curve, he attempted, assisted by Halley, his coadjutor and friend, to represent mathematically the course of the new body, and completely succeeded. Halley energetically took up this branch of astronomy, and finding later on that the comet of 1682 was similar in its path round the sun to two comets previously observed, in 1531 and 1607, recognized it as undoubtedly the same comet, which should, therefore, reappear about 1758.

By the theoretical labors of Newton and by the calculations of Halley the prediction of Seneca was fulfilled; comets, or at least some of them, follow regular orbits. Their return could be foreseen; they ceased to be accidental apparitions; they were true celestial bodies with a fixed and regular course. The marvelous disappeared, or, to speak more correctly, it was transformed. —FLAMMARION *Popular Astronomy*, bk. v, ch. 1, p. 485. (A.)

2092. MASS ENVELOPING HERCULANEUM AND POMPEII—*Rivers of Mud or Alluvium—Aqueous Lava.*—In addition to the ejections which fall on the cone, and that much greater mass which finds its way gradually to the neighboring sea, there is a third portion, often of no inconsiderable thickness, composed of alluviums, spread over the valleys and plains at small distances from the volcano. Aqueous vapors are evolved copiously from volcanic craters during eruptions, and often for a long time subsequently to the discharge of scoriæ and lava: these vapors are condensed in the cold atmosphere surrounding the high volcanic peak, and heavy rains are thus caused. The floods thus occasioned sweep along the impalpable dust and light scoriæ till a current of mud is produced, which is called in Campania "*lava d' acqua*," and is often more dreaded than an igneous stream (*lava di fuoco*), from the greater velocity with which it moves. So late as the 27th of October, 1822, one of these alluviums descended the cone of Vesuvius, and, after overspreading much cultivated soil, flowed suddenly into the villages of St. Sebastian and Massa, where, filling the streets and interior of some of the houses, it suffocated seven persons. It will, therefore, happen very frequently that, towards the base of a volcanic cone, alternations will be found of lava, alluvium, and showers of ashes.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 385. (A., 1854.)

2093. MASTERY, PROGRESSIVE, OF BODY BY MIND—The combined use of anesthetics and antiseptics has almost robbed the surgeon's knife of its terrors, and has enabled the most deeply seated organs to be laid open and operated upon with success. As a result, more lives are probably now saved by surgery than by any other branch of medicine.—WALLACE *The Wonderful Century*, ch. 14, p. 149. (D. M. & Co., 1899.)

2094. MATERIALISM AND IDEALISM —*Contrasted Claims—Possible Reconciliation.*—But when the materialists stray beyond the borders of their path and begin to talk about there being nothing else in the universe but matter and force and necessary laws, I decline to follow them. I go back to the point from which we started, and to the other path of Descartes. I remind you that we have already seen clearly and distinctly, and in a manner which admits of no doubt, that all our knowledge is a knowledge of states of consciousness. "Matter" and "force" are, so far as we can know, mere names for certain forms of consciousness. "Necessary" means that of which we cannot conceive the contrary. "Law" means a rule which we have always found to hold good, and which we expect always will hold good. Thus it is an indisputable truth that what we call the material world is only known to us under the forms of the ideal world: and, as Descartes tells us, our knowledge of the soul is more intimate and certain than our knowledge of the body. If I say that impenetrability is a property of matter, all that I can really mean is that the consciousness I call extension and the consciousness I call resistance constantly accompany one another. Why and how they

are thus related is a mystery. And if I say that thought is a property of matter, all that I can mean is that, actually or possibly, the consciousness of extension and that of resistance accompany all other sorts of consciousness. But, as in the former case, why they are thus associated is an insoluble mystery. From all this it follows that what I may term legitimate materialism, that is, the extension of the conceptions and of the methods of physical science to the highest as well as the lowest phenomena of vitality, is neither more nor less than a sort of shorthand idealism: and Descartes's two paths meet at the summit of the mountain, tho they set out on opposite sides of it.—HUXLEY *Lay Sermons*, serm. 14, p. 340. (G. P. P., 1899.)

2095. MATERIALISM A TENDENCY OF INDIVIDUAL MINDS—*Abstract Conceptions Personified as Living Powers.*—We can see how much and how little is really meant when it is said that law can be traced in all things, and all things can be traced to law. It is a great mistake to suppose that, in establishing this conclusion, the progress of modern investigation is in a direction tending to materialism. This may be and always has been the tendency of individual minds. There are men who would stare into the very burning bush without a thought that the ground on which they stand must be holy ground. It is not now of wood or stone that men make their idols, but of their own abstract conceptions. Before these, borrowing for them the attributes of personality, they bow down and worship.—ARGYLL *Reign of Law*, ch. 2, p. 67. (Burt.)

2096. MATERIALISM BAFFLED BY CONSCIOUSNESS—"You may say or think that this [assumed] issue of consciousness from the clash of atoms is not more incongruous than the flash of light from the union of oxygen and hydrogen. But I beg to say that it is. For such incongruity as the flash possesses is that which I now force upon your attention. The 'flash' is an affair of consciousness, the objective counterpart of which is a vibration. It is a flash only by your interpretation. You are the cause of the apparent incongruity; and you are the thing that puzzles me. . . .

"Your difficulty, then, as I see you are ready to admit, is quite as great as mine. You cannot satisfy the human understanding in its demand for logical continuity between molecular processes and the phenomena of consciousness. This is a rock on which materialism must inevitably split whenever it pretends to be a complete philosophy of life." [Supposed quotation from Bishop Butler.]—TYNDALL *Fragments of Science (the Belfast Address)*, vol. ii, ch. 9, p. 168. (A., 1900.)

2097. MATERIALISM CARRIED TO LOGICAL RESULT—*Personality Obliterated—Reductio ad Absurdum.*—To comprehend completely the consequences of the dogma so confidently enunciated, one should unflinchingly apply it to the most complicated examples. The movements of our tongues and pens, the flashings of our eyes in conversation, are of course events of a material order, and as such their causal antecedents must be exclusively material. If we knew thoroughly the nervous system of Shakespeare, and as thoroughly all his environing conditions, we should be able to show why at a certain period of his life his hand came to trace on certain sheets of paper those crabbed little black marks which we for shortness's sake call the manuscript of "Hamlet." We should understand the rationale of every erasure and alteration therein, and we should understand all this without in the slightest degree acknowledging the existence of the thoughts in Shakespeare's mind. The words and sentences would be taken, not as signs of anything beyond themselves, but as little outward facts, pure and simple. In like manner we might exhaustively write the biography of those two hundred pounds, more or less, of warmish albuminoid matter called Martin Luther, without ever implying that it felt.—JAMES *Psychology*, vol. i, ch. 5, p. 132. (H. H. & Co., 1899.)

2098. MATERIALISM CONFUSES THINGS ESSENTIALLY UNLIKE—*Voice, Man, and Brain Are Not the Thought.*—This equating of mental process and brain function, which makes psychology a department of cerebral physiology, and therefore a part of a general atomic mechanics, sins against the very first rule of scientific logic—that only those connections of facts may be regarded as causal which obtain between generically similar phenomena. Our feelings, thoughts, and volitions cannot be made objects of sensible perception. We can hear the word which expresses the thought, we can see the man who has thought it, we can dissect the brain in which it arose; but the word, the man, and the brain are not the thought. And the blood which circulates in the brain, the chemical changes which take place there, are wholly different from the act of thought itself.—WUNDT *Psychology*, lect. 1, p. 6. (Son. & Co., 1896.)

2099. MATERIALISM GIVES HYPOTHESES WITHOUT FACTS—*Brain Function and Mental Activity Connected—Mental Force Assimilated to Light or Electricity.*—There are numerous experiences which put beyond all doubt the connection of physiological cerebral function on the one hand and of mental activity on the other. And to investigate this connection by means of experiment and observation is assuredly a task worth undertaking. But we do not find that materialism, even in this connection, has made a single noteworthy contribution to our positive knowledge. It has been content to set up baseless hypotheses regarding the dependence of mental function upon physical process; or it has been concerned to refer the nature of mental forces to some known physical agency. No

analogy has been too halting, no hypothesis too visionary, for its purpose. It was for some time a matter of dispute whether the mental force had more resemblance to light or to electricity. Only on one point was there general agreement—that it was not ponderable.—WUNDT *Psychology*, lect. 1, p. 9. (Son. & Co., 1896.)

2100. MATERIALISM INCOMPREHENSIBLE — *Mechanical Evolution of Consciousness Not Presentable in Thought.*— This avowal is repeated with emphasis in the passage to which Professor Virchow's translator draws attention. What, I there ask, is the causal connection between the objective and the subjective—between molecular motions and states of consciousness? My answer is: I do not see the connection, nor am I acquainted with anybody who does. It is no explanation to say that the objective and subjective are two sides of one and the same phenomenon. Why should the phenomenon have two sides? This is the very core of the difficulty. There are plenty of molecular motions which do not exhibit this two-sidedness. Does water think or feel when it runs into frost-ferns upon a window pane? If not, why should the molecular motion of the brain be yoked to this mysterious companion—consciousness? We can form a coherent picture of all the purely physical processes—the stirring of the brain, the thrilling of the nerves, the discharging of the muscles, and all the subsequent motions of the organism. We are here dealing with mechanical problems which are mentally presentable. But we can form no picture of the process whereby consciousness emerges, either as a necessary link or as an accidental by-product of this series of actions.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 408. (A., 1900.)

2101. MATERIALISM MEANS PARALYSIS—There can be little doubt that the further science advances, the more extensively and consistently will all the phenomena of Nature be represented by materialistic formulæ and symbols. But the man of science, who, forgetting the limits of philosophical inquiry, slides from these formulæ and symbols into what is commonly understood by materialism, seems to me to place himself on a level with the mathematician who should mistake the *x*'s and *y*'s, with which he works his problems, for real entities—and with this further disadvantage, as compared with the mathematician, that the blunders of the latter are of no practical consequence, while the errors of systematic materialism may paralyze the energies and destroy the beauty of a life.—HUXLEY *The Physical Basis of Life*, in *Lay Sermons*, p. 146. (A., 1895.)

2102. MATERIALISM, TENDENCY TO—A large part of the age feels profound hatred for what is called spirit. Hence the effort to make man a brute and to lose his soul in matter.—LOTZE *An Address*. (Translated for *Scientific Side-Lights*.)

2103. MATERIALIST'S ANALOGY FALSE — *Thought Not a Secretion.* — The phosphorus philosophers have often compared thought to a secretion. "The brain secretes thought, as the kidneys secrete urine or as the liver secretes bile," are phrases which one sometimes hears. The lame analogy need hardly be pointed out. The materials which the brain *pours into the blood* (cholesterin, creatin, xanthin, or whatever they may be) are the analogues of the urine and the bile, being in fact real material excreta. As far as these matters go, the brain is a ductless gland. But we know of nothing connected with liver and kidney activity which can be in the remotest degree compared with the stream of thought that accompanies the brain's material secretions. —JAMES *Psychology*, vol. i, ch. 3, p. 102. (H. H. & Co., 1899.)

2104. MATERIALIST'S TRIUMPH— *Delight in the Mechanical and the Animal.*—The immense value of the theory of descent in regard to biology consists, as I have already remarked, in its explaining to us the origin of organic forms in a mechanical way, and pointing out their active causes. But however highly and justly this service of the theory of descent may be valued, yet it is almost eclipsed by the immense importance which a single necessary inference from it claims for itself alone. This necessary and unavoidable inference is the theory of the *animal descent of the human race.*

The determination of the position of man in Nature, and of his relations to the totality of things—this question of all questions for mankind, as Huxley justly calls it—is finally solved by the knowledge that man is descended from animals. As a consequence of the theory of descent or transmutation, we are now in a position to establish scientifically the groundwork of a *non-miraculous history of the development of the human race.*—HAECKEL *History of Creation*, vol. i, ch. 1, p. 6. (K. P. & Co., 1899.)

2105. MATERNITY FORESHADOWED—"*Mothering Plants*"—*The Phanerogams Highest in the Vegetable Kingdom.*— In the vegetable kingdom, from the motherlessness of the early cryptogams, we rise to find a first maternity foreshadowed in the flowering tree. It elaborates a seed or nut or fruit with infinite precaution, surrounding the embryo with coat after coat of protective substance, and storing around it the richest foods for its future use. And rudimentary tho the manifestation be, when we remember that this is not an incident in the tree's life, but its whole blossom and crown, it is impossible but to think of this solicitude and motherhood together. So exalted in the tree's life is this provision for others that the botanist, like the zoologist, places the mothering plants at the top of his department of Nature. His highest division is the phanerogams—named, liter-

ally, in terms of their reproductive specialization.—DRUMMOND *Ascent of Man*, ch. 8, p. 268. (J. P., 1900.)

2106. MATERNITY VS. MOTHERHOOD—*The Butterfly Cares for Its Egg—Does Not and Could Not Care for Its Young—Could Not Even Recognize It as Its Own.*—There is a solicitude for the egg of the most extreme kind—for its being placed exactly in the right spot, at the right time, protected from the weather, shielded from enemies, and provided with a first supply of food. The butterfly places the eggs of its young on the very leaves which the coming caterpillar likes the most, and on the under side of the leaf where they will be least exposed—a case which illustrates in a palpable way the essential difference between motherhood and maternity. Maternity here, in the restricted sense of merely adequate physical care, is carried to its utmost perfection. Everything that can be done for the egg is done. Motherhood, on the other hand, is non-existent, is even an anatomical impossibility If a butterfly could live till its egg was hatched—which does not happen—it would see no butterfly come out of the egg, no airy likeness of itself, but an earthbound caterpillar. If it recognized this creature as its child, it could never play the mother to it. The anatomical form is so different that were it starving it could not feed it, were it threatened it could not save it, nor is it possible to see any direction in which it could be of the slightest use to it. It is obvious that Nature never intended to make a mother here; that all that she desired as yet was to perfect the first maternal instinct. And the tragedy of the situation is that on that day when her training to be a true mother should begin she passes out of the world.—DRUMMOND *Ascent of Man*, ch. 8, p. 270. (J. P., 1900.)

2107. MATHEMATICS, BEAUTY OF—*In Music, Sunset, Snow-crystals—Harmony of Nature.*—The notes of the gamut are, besides, nothing else but ratios of number between the sonorous vibrations. Combined in a certain order, these numbers give perfect accord. Here the major mode rouses and enraptures us; there the minor mode affects us and plunges us into melancholy reverie. And yet there is here but a matter of figures! We can not only hear these sounds, but may even see them. Let us make two tuning-forks vibrate by the ingenious method of Lissajous, one vertical, the other horizontal, fitted with little mirrors reflecting a luminous point on a screen. If the two tuning-forks are in unison and give exactly the same note, the combination of the two vibrations rendered visible on the screen by the little mirrors, which inscribe them in lines of light, produces a perfect circle—that is to say, the simplest geometrical figure; as the amplitude of the vibrations diminishes, the circle flattens, becomes an ellipse, then a straight line. . . . Yes, in everything and everywhere numbers rule the world.

Why, however, seek in scientific analysis testimony to the harmony which Nature has shed over all her works? Altho it may be necessary for us to rise to the ideal of music, to contemplate the beautiful colors of the sky or the splendor of the setting sun, we may on a dull winter day, in the gray and monotonous hours when the snow falls in innumerable flakes, examine with the microscope some of these flakes, and the geometrical beauty of these light crystals will fill us with admiration. As Pythagoras said: "God works everywhere by geometry," ἀεὶ ὁ θεὸς γεωμετρεῖ.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 1, pp. 223-26. (A.)

2108. MATHEMATICS, DEVELOPMENT OF—*Arithmetic Narrowly Limited before Decimal System.*—The Greeks, the Romans, the Egyptians, the Jews, and the Chinese had all such cumbrous systems that anything like a science of arithmetic, beyond very simple operations, was impossible; and the Roman system, by which the year 1888 would be written MDCCCLXXXVIII, was that in common use in Europe down to the fourteenth or fifteenth centuries, and even much later in some places. Algebra, which was invented by the Hindus, from whom also came the decimal notation, was not introduced into Europe till the thirteenth century, altho the Greeks had some acquaintance with it; and it reached Western Europe from Italy only in the sixteenth century. It was, no doubt, owing to the absence of a sound system of numeration that the mathematical talent of the Greeks was directed chiefly to geometry, in which science Euclid, Archimedes, and others made such brilliant discoveries. It is, however, during the last three centuries only that the civilized world appears to have become conscious of the possession of a marvelous faculty, . . . the full grandeur of which can be appreciated only by those who have devoted some time (even if unsuccessfully) to the study.—WALLACE *Darwinism*, ch. 15, p. 313. (Hum.)

2109. MATHEMATICS MINISTERS TO ALL SCIENCE—While the algebra of the Arabs, by means of that which they had acquired from the Greeks and Indians, combined with the portions due to their own invention, acted so beneficially on the brilliant epoch of the Italian mathematicians of the Middle Ages, notwithstanding a great deficiency in symbolical designations, we likewise owe to the same people the merit of having furthered the use of the Indian numerical system from Bagdad to Cordova by their writings and their extended commercial relations. Both these effects—the simultaneous diffusion of the knowledge of the science of numbers and of numerical symbols with value by position—have variously, but powerfully, favored the advance of the mathematical portion of natural sci-

ence, and facilitated access to the more abstruse departments of astronomy, optics, physical geography, and the theories of heat and magnetism, which, without such aids, would have remained unopened.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 227. (H., 1897.)

2110. MATHEMATICS OF THE UNIVERSE—*Full Realization Possible Only to the Divine Mind.*—But ascend with me above the dust, above the cloud, to the realms of the higher geometry, where the heavens are never obscured; where there is no impure vapor, and no delusive or imperfect observation; where the new truths are already arisen, while they are yet dimly dawning upon the earth below; where the earth is a little planet; where the sun has dwindled to a star; where all the stars are lost in the Milky Way, to which they belong; where the Milky Way is seen floating through space like any other nebula; where the whole great girdle of the nebulæ has diminished to an atom, and has become as readily and as completely submissive to the pen of the geometer, and the slave of his formula, as the single drop which falls from the cloud, instinct with all the forces of the material world. Try with me the precision of measure with which the universe has been meted out; observe how exactly all the parts are fitted to the whole and to each other, and then declare who was present in the council-chamber when the Lord laid the foundations of the earth.—BENJAMIN PIERCE *Address on retiring from the duties of President (Proceedings of Amer. Assoc. for Advancement of Science,* vol. viii, 1854, p. 2).

2111. MATHEMATICS ON WORD OF HONOR—*Story of the Duc d'Angoulême.*—I can hardly imitate here that Academician who, in order to prove a mathematical truth, was contented to give his word of honor because the intelligence of his pupil was not equal to comprehending the demonstration. This pupil was the Duke d'Angoulême, and I venture to hope that my readers are somewhat superior to him in that respect. We know that when he was nominated Chief Minister of Marine it was perceived with dismay that he could hardly count up to a hundred. The most celebrated geometer of France was at once sent for to instruct him in the mathematics, as they said in old times. But it was in vain that he tried to prove the most elementary principles to his august pupil. The latter listened with exquisite politeness, but shook his head with a mild air of incredulity. One day, at the end of the arguments, the poor master exclaimed, "My lord, I give you my word!" "Why did you not say so sooner, sir?" said the Duke, bowing: "I shall never permit myself to doubt it."—FLAMMARION *Popular Astronomy,* bk. v, ch. 2, p. 491. (A.)

2112. MATHEMATICS, POWER OF, IN ASTRONOMY—*Discovery of Neptune.*—It has been said, with reason, that the labors of astronomy are those which give the highest measure of the powers of the human mind. The discovery of Neptune, due to the sole power of numbers, is one of the most eloquent witnesses of this truth. The existence of this planet in the sky was revealed by mathematics. This world, distant more than 2,700 millions of miles from our terrestrial station, is absolutely invisible to the naked eye. The perturbations manifested by the motion of the planet Uranus permitted the mathematician to say that the cause of these perturbations was an unknown planet which revolved beyond Uranus at about such a distance, and which, to produce the effect observed, should be found at a certain point of the starry sky. A telescope was directed towards the point indicated, the unknown was searched for, and in less than an hour it was found!—FLAMMARION *Popular Astronomy,* bk. iv, ch. 9, p. 463. (A.)

2113. MATTER AND FORCE INFERIOR TO MIND—*Probability that Higher Attributes Exist in the Universe.*—No philosophy can be true which allows that we see in Nature the most intimate relations with our intellectual conceptions of space and time and force and numerical proportion, but denies that we can ever see any similar relation with our conceptions of purpose and design, or with those still higher conceptions which are embodied in our sense of justice and in our love of righteousness, and in our admiration of the "quality of mercy." These elements in the mind of man are not less certain than others to have some correlative in the mind which rules in Nature. Assuredly, in the supreme government of the universe these are not less likely than other parts of our mental constitution to have some part of the natural system related to them—so related that the knowledge of that system shall be at once their interpretation and fulfilment. Neither brute matter nor inanimate force can supply either the one or the other. If there be one truth more certain than another, one conclusion more securely founded than another, not on reason only, but on every other faculty of our nature, it is this—that there is nothing but mind that we can respect; nothing but heart that we can love, nothing but a perfect combination of the two that we can adore.—ARGYLL *Unity of Nature,* ch. 8, p. 184. (Burt.)

2114. MATTER AND MOTION—*Made by Descartes the Basis of All Phenomena of the Universe.*—Descartes saw that the discoveries of Galileo meant that the remotest parts of the universe were governed by mechanical laws, while those of Harvey meant that the same laws presided over the operations of that portion of the world which is nearest to us, namely, our own bodily frame. And crossing the interval between the center and its vast circumference by one of the great strides of genius, Descartes sought to resolve all the phenomena of the universe into matter and motion, or forces operating

according to law. This grand conception, which is sketched in the "Discours," and more fully developed in the "Principes" and in the "Traité de l'Homme," he worked out with extraordinary power and knowledge; and with the effect of arriving, in the last-named essay, at that purely mechanical view of vital phenomena towards which modern physiology is striving.—HUXLEY *Lay Sermons*, serm. 14, p. 331. (G. P. P., 1899.)

2115. MATTER, ATOMIC CONSTITUTION OF—*Hypothesis of Centers of Force—Phenomena Not So Explained.*—According to this celebrated hypothesis [the corpuscular hypothesis of Boscovich], a portion of matter consists of an assemblage in space of an indefinite number of points kept at a given distance by attracting and repelling forces: these points have relative position, but not magnitude, and are merely centers of action of the forces which affect our senses, and since all our knowledge of matter is derived from the action of these forces, to infer that these points are anything more than the centers of forces is going beyond our premises.

This hypothesis readily explains the statical properties of bodies, such as elasticity, porosity, impenetrability, solidity, liquidity, crystallization, resistance to compression when a force is applied to either side of the body, etc.; but it fails to account for the dynamic phenomena of masses of matter, or those which are referable to the three laws of motion. It is not therefore enough that we assume, as the elements of matter, an assemblage of points in space from which merely emanate attracting and repelling forces: we must also suppose these points to be endowed with inertia, or a tendency to resist a change of state, whether of rest or motion, and a tendency to move in a straight line; also to possess the property of preserving the effects of a number of impulses, as well as that of transforming motion from one point to another, the one losing as much motion as the other gains. But the admission of the existence of points with such qualities brings us back to the Newtonian hypothesis of matter.—HENRY *The Atomic Constitution of Matter, Scientific Writings*, vol. i, p. 256. (Sm. Inst., 1886.)

2116. ——— ——— *Hypothesis of Newton—One Kind of Matter throughout All Space—Its Four States—The Imponderables—Ether Cannot Exhibit Weight.*—We may assume, with Newton, the existence of one kind of matter diffused throughout all space, and existing in four states, namely, the ethereal, the aeriform, the liquid, and the solid. This method of presenting the atomic hypothesis of the constitution of matter may at first sight appear startling; but on a little reflection it will be found a necessary consequence of the attempt to explain the mechanical phenomena of matter by an assemblage of separate atoms. It may be objected to the assumption of one kind of matter that the fact of the imponderable nature of light, heat, electricity, and magnetism require at least two kinds of matter; but if we adopt the theory of undulation, the phenomena of the "imponderables" (as they are called) are merely the results of the motions of the atoms of the ethereal medium combined in some cases with the motion of the atoms of the body; and since the vibrations of the atoms of a mass of matter do not increase the attraction of the earth on the mass, an increase of temperature in a body cannot change its weight; and also because the ethereal medium fills all space, a portion of this medium can no more exhibit weight than a quantity of air when weighed in the midst of the atmosphere.—HENRY *Atomic Constitution of Matter, Scientific Writings*, vol. i, p. 257. (Sm. Inst., 1886.)

2117. ——— ——— *Materiality of Atoms—The Ether a Form of Matter, Filling All Space.*—According to the view we have given, a portion of matter consists of an assemblage of indivisible and indestructible atoms endowed with attracting and repelling forces, and with the property of obedience to the three laws of motion [viz.: inertia, coexistence of separate motions, and equality of action and reaction]. All the other properties, and indeed all the mechanical phenomena of matter, so far as they have been analyzed, are probably referable to the action of such atoms, arranged in groups of different orders, . . . the distance in all cases between any two atoms being much greater than the diameter of the atoms or molecules. We are obliged to assume the existence of an ethereal medium formed of atoms, which are endowed with precisely the same properties as those we have assigned to common matter; and this assumption leads us to the inference that matter is diffused through all space.

That something exists between us and the sun, possessing the properties of matter, may be inferred from the simple fact that time is required for the transmission of light and heat through the intervening space. . . . That the phenomena of light and heat from the sun are not the effect of the transmission of mere force (without intervening matter), such as that of attraction and repulsion, is evident from the fact that these [latter] actions require no perceptible time for their transmission to the most distant parts of the solar system. If the sun were to be at once annihilated, the planet Neptune would at the same instant begin to move in a tangent to its present orbit.—HENRY *The Atomic Constitution of Matter, Scientific Writings*, vol. i, p. 257. (Sm. Inst., 1886.)

2118. MATTER IN SPACE AND IN TIME—"There are only two different aspects," says Dr. Thomas Brown, "in which matter can be viewed. We may consider it

simply as it exists in space or as it exists in time. As it exists in space we inquire into its composition, or, in other words, endeavor to discover what are the elementary bodies that coexist in the space which it occupies; as it exists in time, we inquire into its susceptibilities or its powers, or, in other words, endeavor to trace all the various changes which have already passed over it, or of which it may yet become the subject."—MILLER *Old Red Sandstone*, ch. 12, p. 211. (G. & L., 1851.)

2119. MATTER, MORAL RELATIONS OF—*Man Communicates His Own Character—Use or Abuse of Material.*—Nothing, however indifferent in itself, can come into human hands without acquiring thereby an ethical, social, political, or even religious significance. An ounce of lead or a dynamite cartridge may be in itself a thing altogether destitute of any higher significance than that depending on physical properties; but let it pass into the power of man, and at once infinite possibilities of good and of evil cluster round it according to the use to which it may be applied. This depends on essential powers and attributes of man himself, of which he can no more be deprived than matter can be denuded of its inherent properties; and if the evils arising from misuse of these powers trouble us, we may at least console ourselves with the reflection that the possibility of such evils shows man to be a free agent, and not an automaton. All this is eminently applicable to science.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 12. (A. B. P. S.)

2120. MATTER, MUTABILITY OF—*Change Alone Is Constant.*—All things in existence are nothing but temporary phases of the transition of matter, appearing greater or smaller, of longer or shorter duration. Nothing but change is constant.—MERSHALL *(A Lecture)*. (Translated for *Scientific Side-Lights.)*

2121. MATTER RECOGNIZED BY RESISTANCE—*The Not-me—The Pull of Air on a Sail.*—We must, therefore, seek a satisfactory definition of matter elsewhere: and we find the clue to it in the consideration that the sense of effort we experience in antagonizing the downward pressure of a body, is but a particular case of our more general cognition of *resistance*. When we project our hand against a hard and fixed solid body, our consciousness of its resistance to our pressure is exactly that which we experience when we try to raise a weight that we have not strength to lift; whilst if that solid be either yielding in its parts or movable as a whole, we measure its resistance, as in lifting a weight, by our sense of the effort necessary to overcome it. When we move our hand through a liquid, we are conscious of a resistance to its motion, which is greater or less according to the "viscosity" of the liquid. And when we move our open hand through air at rest, we are still conscious of a resistance, our sense of it being augmented by an extension of the surface moved, as in the act of fanning; whilst if the air is in motion, we feel its pressure on the sail of a boat by the "pull" of the sheet we hold in our hand, or on the sails of a windmill by the rotation it imparts, the force of which we can estimate by the effort we must put forth to resist it. Attenuate any kind of air or gas as we may, its resistance can still be made apparent by the like communication of its own motion to solid bodies.—CARPENTER *Nature and Man*, lect. 12, p. 356. (A., 1889.)

2122. MAZE OF ASTEROIDAL ORBITS—*Labyrinth of the Heavens.*—The crowd of orbits [of asteroids] invites attentive study. D'Arrest remarked in 1851, when only thirteen minor planets were known, that supposing their paths to be represented by solid hoops, not one of the thirteen could be lifted from its place without bringing the others with it. The complexity of interwoven tracks thus illustrated has grown almost in the numerical proportion of discovery. Yet no two actually intersect, because no two lie exactly in the same plane, so that the chances of collision are at present *nil*. There is only one case, indeed, in which it seems to be eventually possible. M. Lespiault has pointed out that the curves traversed by "Fidès" and "Maïa" approach so closely that a time may arrive when the bodies in question will either coalesce or unite to form a binary system.

The maze threaded by the 375 asteroids contrasts singularly with the harmoniously ordered and rhythmically separated orbits of the larger planets. Yet the seeming confusion is not without a plan.—CLERKE *History of Astronomy*, pt. ii, ch. 8, p. 347. (Bl., 1893.)

2123. MEANING OF HISTORY—*Character and Achievement Transcend Psychology.*—Does history really mean for us what psychological and economical and statistical laws put in its place? Are "heroism and hero-worship" empty words? Have Kant and Fichte, Carlyle and Emerson, really nothing to say any more, and are Comte and Buckle our only apostles? Do we mean, in speaking of Napoleon and Washington, Newton and Goethe, those complicated chemical processes which the physiologist sees in their life, and those accompanying psychical processes which the psychologist enumerates between their birth and their death? Do we really still think historically if we consider the growth of the nations and this gigantic civilization on earth as the botanist studies the growth of the mold which covers a rotten apple? Is it really only a difference of complication?—MÜNSTERBERG *Psychology and Life*, ch. 1 p. 17. (H. M. & Co., 1899.)

2124. MEASURE OF ANCIENT GLACIER—*A Mountain for a Plummet.*—Mount Washington, for instance, is over six thousand feet high, and the rough, unpolished

surface of its summit, covered with loose fragments, just below the level of which glacier-marks come to an end, tells us that it lifted its head alone above the desolate waste of ice and snow. In this region, then, the thickness of the sheet cannot have been much less than six thousand feet, and this is in keeping with the same kind of evidence in other parts of the country; for, wherever the mountains are much below six thousand feet, the ice seems to have passed directly over them, while the few peaks rising to that height are left untouched. And while we can thus sink our plummet from the summit to the base of Mount Washington and measure the thickness of the mass of ice, we have a no less accurate indication of its extension in the undulating line marking the southern termination of the drift.—AGASSIZ *Geological Sketches*, ser. ii, p. 98. (H. M. & Co., 1896.)

2125. MEASURE OF THE POWER OF HEAT—It is singular how a modern investigator will repeat an experiment that dates almost from the dawn of human skill, and discover a significance in it concealed until the hour of his interrogation. Ages ago the savage must have remarked that the hard work of grinding and polishing stone gave rise to heat. It remained for James Prescott Joule, of Manchester, as recently as 1843, to carry forward by a decisive step the experiments which had begun with the savage and had been brought to a new meaning by Count Rumford. Joule set himself to find out exactly how much heat is equivalent to a given amount of work. He applied sinking weights to the agitation of water, and, taking elaborate precautions against the escape of heat, he found that 1,390 pounds in descending one foot could raise the temperature of a pound of water by 1° C. Here at last was rendered an accurate account of the enormous debt due to the ability to kindle fire.—ILES *Flame, Electricity, and the Camera*, ch. 7, p. 82. (D. & McC., 1900.)

2126. MEASUREMENT AMONG NORTH-AMERICAN MOUND-BUILDERS—*Exactness of Lines, Angles, and Circles.*—The squares or other rectangular works never have a ditch, and the earth of which they are composed appears to have been taken up evenly from the surface, or from large pits in the neighborhood. They vary much in size; five or six of them, however, are "exact squares, each side measuring one thousand and eighty feet—a coincidence which could not possibly be accidental, and which must possess some significance." The circles also, in spite of their great size, are so nearly round that the American archæologists consider themselves justified in concluding that the mound-builders must have had some standard of measurement, and some means of determining angles.—AVEBURY *Prehistoric Times*, ch. 8, p. 246. (A., 1900.)

2127. MEASUREMENT OF ENERGY—*The Foot-pound—Exactness of Science.*—This brings us to the discussion of what is called the "mechanical equivalent" of heat. It has been proven by experiment that the quantity of heat necessary to raise one pound of water to the temperature of one degree F. is equal to that generated by a pound weight falling from a height of 772 feet against the surface of the earth. Conversely, an amount of heat necessary to raise a pound of water one degree F. in temperature would, if all is converted into mechanical energy, be sufficient to raise a pound weight 772 feet above the earth. The unit of measurement called the "foot-pound" has been adopted as a means of determining the amount of energy expended in doing a given piece of work. The foot-pound is a unit of energy as expressed in work, and is that amount of energy which is necessary to raise one pound weight one foot high against the force of gravity. It follows from this that the amount of heat necessary to raise a pound of water one degree F. is equal to 772 foot-pounds, which constitutes the mechanical equivalent of heat. We thus have a means of measuring energy, whether mechanical or molecular.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 1, p. 13. (F. H. & H., 1900.)

2128. MEASUREMENTS OF HEAT OF SUN—*Coal Needed for Equal Supply.*—The total amount of solar heat received by the earth in a year, if distributed uniformly over the earth's surface, would be sufficient to liquefy a layer of ice 100 feet thick, covering the whole earth. The heat of the sun, if used to melt a stratum of ice applied to the sun's surface, would liquefy it at the rate of 2,400 feet an hour. It would boil per hour 700,000 millions of cubic miles of ice-cold water. Expressed in another form, the heat given out every hour by the sun is equal to that which would be generated by the combustion of a layer of coal, ten feet thick, entirely surrounding the sun; hence the heat emitted in a year is equal to that which would be produced by the combustion of a layer of coal seventeen miles in thickness.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 516. (A., 1900.)

2129. MEASURES AMONG PRIMITIVE MEN—*The Human Body the Universal Standard.*—These ancient manufacturers and builders had no government standards of measuring their work, but referred everything to their bodies. This system was far more accurate among rude peoples, where anthropometric differences between the sexes and between individuals were very slight. Many witnesses confirm the opinion that every weapon or chungke-pole had its proportion to the owner. Dr. Mathews says that the Navajo pole for the great hoop game was twice the span long, and Mr. Dorsey found that the Omaha arrow had to measure from the inner angle of the elbow to the tip of the middle finger, and thence

over the back of the hand to the wrist bone. I have examined many hundreds of quivers, and have always found the arrows to be of the same length, while those of the tribe resemble in general appearance, but vary slightly in length for each man. Dr. Dorsey found the Naltunne, on Siletz Agency, in Oregon, using the double arm's length, the single arm's length, half the span, the cubit, the half-cubit, the hand-length, the hand-width, the finger-width, and from the tip of the elbow across the body to the end of the middle finger of the other hand. In most of these cases the starting-point is the meeting of the tips of the thumb and index-finger. . . .

Quite a series of measures were recognized from the ground to the upper portions of the body, to the ankle, to the upper portion of the calf, to the knee-cap, to the girdle, etc.—MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology*, p. 77). (Sch. P. C.)

2130. MEASURES, ANCIENT — *The Human Body Furnished the Early Standards—The Cubit, Foot, Span, Nail, Ell, and Pace.*—It may be fairly guessed that man first measured, as he first counted, on his own body. When barbarians tried by finger-breadths how much one spear was longer than another, or when in building huts they saw how to put one foot before the other to get the distance right between two stakes, they had brought mensuration to its first stage. We sometimes use this method still for rough work, as in taking a horse's height by hands, or stepping out the size of a carpet. If care is taken to choose men of average size as measures, some approach may be made to fair measurement in this way. That it was the primitive way can hardly be doubted, for civilized nations who have more exact means still use the names of the body-measures. Besides the cubit, hand, foot, span, nail, . . . we have in English the ell (of which the early meaning of arm or forearm is seen in *el*-bow, the arm-bend), also the fathom or cord stretched by the outspread arms in sailors' fashion, and the pace or double step (Latin *passus*) of which a thousand *(mille)* made the mile.—TYLOR *Anthropology*, ch. 13, p. 316. (A., 1899.)

2131. MECHANIC MASTER OF THE EARTH— *Wonders Wrought by Command of Natural Forces.*—A mechanic is one who is skilled in the use of tools, who works habitually in some kind of material to shape it, who makes thereof something useful. He is, therefore, an artisan or artificer. He practises always some kind of elaborative industry, by which materials are changed in form to adapt them to the use of others. Finally, he is a utilitarian. His works are designed to supply some need. As distinguished from an artist, who works in order to give pleasure, this man toils to feed the hungry, to clothe the naked, to house the shelterless, to enable all mankind to do their work, whatever it may be. The modern mechanic is absolute master of the earth. There is little that he cannot lift, remove, dissolve, penetrate, transform. A catalog of his tools and appliances would define all the trades and industries of the world. All the material resources of the earth, mineral, vegetable, animal, are his. The winds, the waters, the fire, the sunlight, the lightning are his servants. He understands the nature and transformations of forces, the constitution and molecular activities of matter, the nature of living beings. He has devised means of multiplying himself, of converting space and time and weight, one into the other. And now he dreams of new applications of force and combines with his fellows to construct and govern society. The most favored nations have not always been so blest, but the mechanic, like every other product of Nature or of culture, is the result of many evolutions.—MASON *Aboriginal American Mechanics (Memoirs of International Congress of Anthropology*, p. 69). (Sch. P. C.)

2132. MECHANICS, A MONKEY'S COMPREHENSION OF — *Perseverance in Learning.*—To-day he [a brown capuchin monkey] obtained possession of a hearth-brush, one of the kind which has the handle screwed into the brush. He soon found the way to unscrew the handle, and having done that he immediately began to try to find out the way to screw it in again. This he in time accomplished. At first he put the wrong end of the handle into the hole, but turned it round and round the right way for screwing. Finding it did not hold, he turned the other end of the handle and carefully stuck it into the hole, and began again to turn it the right way. It was of course a very difficult feat for him to perform, for he required both his hands to hold the handle in the proper position and to turn it between his hands in order to screw it in, and the long bristles of the brush prevented it from remaining steady or with the right side up. He held the brush with his hind hand, but even so it was very difficult for him to get the first turn of the screw to fit into the thread; he worked at it, however, with the most unwearying perseverance until he got the first turn of the screw to catch, and he then quickly turned it round and round until it was screwed up to the end. The most remarkable thing was that, however often he was disappointed in the beginning, he never was induced to try turning the handle the wrong way; he always screwed it from right to left. As soon as he had accomplished his wish, he unscrewed it again, and then screwed it in again the second time rather more easily than the first, and so on many times. When he had become by practise tolerably perfect in screwing and unscrewing, he gave it up and took to some other amusement. One remarkable thing is that he should take so much trouble to do that which is no material benefit to

him. The desire to accomplish a chosen task seems a sufficient inducement to lead him to take any amount of trouble. This seems a very human feeling, such as is not shown, I believe, by any other animal. It is not the desire of praise, as he never notices people looking on; it is simply the desire to achieve an object for the sake of achieving an object, and he never rests nor allows his attention to be distracted until it is done.—ROMANES *Animal Intelligence (extract from diary of author's sister)*, ch. 17, p. 490. (A., 1899.)

2133. MECHANICS OF AMERICA BEFORE COLUMBUS—*Variety of Tools—A True Stone Age.*—The handy tools of our day do not change the mode of action, they do not add many new ideas out and out. They substitute better material, work more rapidly, and introduce cooperation in their actions. They are more often now driven by power rather than by hand. But the American mechanic before the days of Columbus had a respectable tool-chest, as his works will testify. The knives, shears, planes, axes, adzes, chisels, gouges, and saws of the aborigines of the Western Continent were of stone for the most part. The use of teeth, shell, and copper for such purposes was limited. Bronze may have sparingly entered into the list of cutting-tools among the advanced nations. For cutting, the Americans used both chipped and polished implements, and had a great variety of forms for working in hides or wood, or in ivory, antler, horn, slate, and such hard materials. These tools were best developed in the places where the best material abounded, such as British Columbia or the West Indies. . . . Mortars for paint, tobacco, and food, and metates for food and clay and chocolate, are to be found in all latitudes. From a hole in a natural boulder, in which an elongated pebble was worked, to the intricate California acorn-grinding apparatus, with its exquisite basketry hopper, or to a Mexican metate, tastefully carved, there are several grades of technical education, filled by the triturating and rubbing apparatus of other tribes. There were no mills in America four hundred years ago, turned either by man or beast. The grinding was done with metates and in mortars. For making holes, the implement of chief importance is universal, namely, a sharpened bone, used as a marlinespike, is employed by sailors. The skin-sewer and the basket-maker could not do without it, and hundreds of examples are found in their graves.—MASON *Aboriginal American Mechanics (Memoirs of International Congress of Anthropology*, p. 72). (Sch. P. C.)

2134. MEDITERRANEAN, ABYSSES OF—*Unsolved Problems of Science.*—The central abysses, therefore, of this sea [the Mediterranean] are, in all likelihood, at least as deep as the Alps are high; and, as at the depth of seven hundred fathoms only, water has been found to contain a proportion of salt four times greater than at the surface, we may presume that the excess of salt may be much greater at the depth of two or three miles. After evaporation, the surface-water becomes impregnated with a slight excess of salt, and, its specific gravity being thus increased, it instantly falls to the bottom, while lighter water rises to the top, or flows in laterally, being always supplied by rivers and the current from the Atlantic. The heavier fluid, when it arrives at the bottom, cannot stop if it can gain access to any lower part of the bed of the sea, not previously occupied by water of the same density.

How far this accumulation of brine can extend before the inferior strata of water will part with any of their salt, and what difference in such a chemical process the immense pressure of the incumbent ocean, or the escape of heated vapors, thermal springs, or submarine volcanic eruptions, might occasion, are questions which cannot be answered in the present state of science.—LYELL *Principles of Geology*, bk. ii, ch. 20, p. 336. (A., 1854.)

2135. MELODY AND MOTION UNITED—Many songsters in widely different families possess the habit of soaring and falling alternately while singing, and in some cases all the aerial postures and movements, the swift or slow descent, vertical, often with oscillations, or in a spiral, and sometimes with a succession of smooth oblique lapses, seem to have an admirable correspondence with the changing and falling voice—melody and motion being united in a more intimate and beautiful way than in the most perfect and poetic forms of human dancing.—HUDSON *Naturalist in La Plata*, ch. 19, p. 274. (C. & H., 1895.)

2136. MEMORY A MARVELOUS PHENOMENON — Remember! Have you ever reflected on the marvelous phenomenon we call memory? There is nothing we know better, nothing more familiar. There is no greater mystery. Every hour, every moment, external facts, scenes, utterances, physical sensations, ideas, and moral impressions are engraving themselves upon our minds and contributing to form the being which is ourself. Without memory we evidently should be nothing, for the present moment is continually vanishing, and we oscillate perpetually between the past and the future. It is our past that makes something of us, that imparts to us intellectual or moral value; every judgment we form presupposes memory.—BERSIER "*Souviens Toi*" *(a Sermon)*. (Translated for *Scientific Side-Lights.*)

2137. MEMORY A MYSTERY—*A Resurrection of the Buried Past.*—The mystery of memory lies in the apparent immediateness of the mind's contact with the vanished past. In "looking back" on our life, we seem to ourselves for the moment to rise above the limitations of time, to undo

its work of extinction, seizing again the realities which its on-rushing stream had borne far from us. Memory is a kind of resurrection of the buried past: as we fix our retrospective glance on it, it appears to start anew into life; forms arise within our minds which, we feel sure, must faithfully represent the things that were.—SULLY *Illusions*, ch. 10, p. 231. (A., 1897.)

2138. MEMORY AND THOUGHT—*Dependence of, on Bodily Condition—Evidence of Old Age, Delirium, and Sleep.*—The memory rises and falls with the bodily condition, being vigorous in our fresh moments, and feeble when we are fatigued or exhausted. It is related by Sir Henry Holland that on one occasion he descended, on the same day, two deep mines in the Hartz Mountains, remaining some hours in each. In the second mine he was so exhausted with inanition and fatigue that his memory utterly failed him; he could not recollect a single word of German. The power came back after taking food and wine. Old age notoriously impairs the memory in ninety-nine men out of a hundred. In the delirium of fever the sense of hearing sometimes becomes extraordinarily acute. Among the premonitory symptoms of brain disease has been noticed an unusual delicacy of the sense of sight; the physician suspects that there is already congestion of blood, to be followed perhaps by effusion. Any person fancying that trains of thinking have little dependence on the bodily organs should also reflect on such facts as these. When walking, or engaged in any bodily occupation, if an interesting idea occurs to the mind, or is imparted to us by another person, we suddenly stop, and remain at rest, until the excitement has subsided. . . . Why should sleep suspend all thought, except the incoherency of dreaming (absent in perfect sleep), if a certain condition of the bodily powers were not indispensable to the intellectual functions?—BAIN *Mind and Body*, ch. 2, p. 3. (Hum., 1880.)

2139. MEMORY, ANOMALIES OF—*Sudden Recollection of Something Sought in Vain.*—There are many irregularities in the process of forgetting which are as yet unaccounted for. A thing forgotten on one day will be remembered on the next. Something we have made the most strenuous efforts to recall, but all in vain, will, soon after we have given up the attempt, saunter into the mind, as Emerson somewhere says, as innocently as if it had never been sent for. Experiences of bygone date will revive after years of absolute oblivion, often as the result of some cerebral disease or accident which seems to develop latent paths of association, as the photographer's fluid develops the picture sleeping in the collodion film. The oftenest quoted of these cases is Coleridge's:

"In a Roman Catholic town in Germany, a young woman, who could neither read nor write, was seized with a fever, and was said by the priests to be possessed of a devil, because she was heard talking Latin, Greek, and Hebrew. Whole sheets of her ravings were written out, and found to consist of sentences intelligible in themselves, but having slight connection with each other. Of her Hebrew sayings, only a few could be traced to the Bible, and most seemed to be in the rabbinical dialect. All trick was out of the question; the woman was a simple creature; there was no doubt as to the fever. It was long before any explanation, save that of demoniacal possession, could be obtained. At last the mystery was unveiled by a physician, who determined to trace back the girl's history, and who, after much trouble, discovered that at the age of nine she had been charitably taken by an old Protestant pastor, a great Hebrew scholar, in whose house she lived till his death. On further inquiry it appeared to have been the old man's custom for years to walk up and down a passage of his house into which the kitchen opened, and to read to himself with a loud voice out of his books. The books were ransacked, and among them were found several of the Greek and Latin fathers, together with a collection of rabbinical writings. In these works so many of the passages taken down at the young woman's bedside were identified that there could be no reasonable doubt as to their source."—JAMES *Psychology*, vol. i, ch. 16, p. 681. (H. H. & Co., 1899.)

2140. MEMORY COEXTENSIVE WITH INTEREST—The attention which we lend to an experience is proportional to its vivid or interesting character; and it is a notorious fact that what interests us most vividly at the time is, other things equal, what we remember best. An impression may be so exciting emotionally as almost to leave a scar upon the cerebral tissues.—JAMES *Psychology*, vol. i, ch. 16, p. 670. (H. H. & Co., 1899.)

2141. MEMORY DEPENDS ON MULTIPLE ASSOCIATIONS—*Inherent Absurdity of Cramming System.*—You now see why "cramming" must be so poor a mode of study. Cramming seeks to stamp things in by intense application immediately before the ordeal. But a thing thus learned can form but few associations. On the other hand, the same thing recurring on different days, in different contexts, read, recited on, referred to again and again, related to other things and reviewed, gets well wrought into the mental structure. This is the reason why you should enforce on your pupils habits of continuous application. There is no moral turpitude in cramming. It would be the best, because the most economical, mode of study if it led to the results desired. But it does not, and your older pupils can readily be made to see the reason why.—JAMES *Talks to Teachers*, ch. 12, p. 129. (H. H. & Co., 1900.)

2142. MEMORY ESSENTIAL TO ALL MENTAL ACTION—*No Personal Identity, No Real Mind without Memory.*—Memory is the most important function of the brain; without it, life would be a blank. Our knowledge is all based on memory. Every thought, every action, our very conception of personal identity, is based on memory. Without memory, all experience would be useless; reasoning would be based on insufficient data, and would be, therefore, fallacious. A bad memory makes an otherwise able man appear foolish; he looks his acquaintances in the face without recognizing them; he forgets his appointments, and tho he may be well acquainted with the ordinary rules of society, he forgets what to do under particular circumstances. — ELDRIDGE-GREEN *Memory and Its Cultivation*, ch. 1, p. 1. (A., 1900.)

2143. MEMORY, FREAKS OF—*Retracing Links of Association.*—When a man tries to retrace some "train of thought" which has formerly passed through his mind, but of which he only remembers that the subject of it had been before him, he may often recover it by following it out (as it were) from the original starting-point; when the whole, with its conclusions, will often flash into the mind at once.

Thus, the writer well recollects that, when going to register the birth of one of his own children, he found, when approaching the office, that he had entirely forgotten the intended name, which had been decided on after a considerable amount of domestic discussion, and only brought it to his remembrance by "trying back" over the reasons which had determined the one finally selected.—CARPENTER *Mental Physiology*, ch. 10, p. 449. (A., 1900.)

2144. MEMORY, LAPSE OF—*Shock May Cause—Questions of Veracity May Be So Explained.*—Numerous cases are on record of a person receiving some great shock, and on recovery being found to have lost the memory not only of the circumstance which gave rise to the shock, but also of a certain period of time directly preceding it, all the events and circumstances which happened during that time being forgotten, the last circumstance remembered, preceding the blank, often being some trivial incident. . . . A young lady, having ascended an iron staircase, became giddy and fell down, being afterwards found insensible at the bottom. After her recovery, she had no recollection of the cause of her illness or the place where she had fallen down. Five years afterwards, she happened to go to the same place again and immediately the whole flashed into her mind; she remembered becoming giddy and falling.—ELDRIDGE-GREEN *Memory and Its Cultivation*, pt. i, ch. 3, pp. 20-22. (A., 1900.)

2145. ——— ——— *Work Forgotten by Author—Experience of Sir Walter Scott.*—One of the most curious examples of this limited loss of memory occurred in the case of Sir Walter Scott, who, having produced one of his best works ["The Bride of Lammermoor"] under the pressure of severe illness, was afterwards found to have entirely forgotten what he had thus constructed.

"The book (says James Ballantyne) was not only written, but published, before Mr. Scott was able to rise from his bed, and he assured me that when it was first put into his hands in a complete shape, he did not recollect one single incident, character, or conversation it contained! He did not desire me to understand, nor did I understand, that his illness had erased from his memory the original incidents of the story, with which he had been acquainted from his boyhood. These remained rooted where they had ever been; or, to speak more explicitly, he remembered the general facts of the existence of the father and mother, of the son and daughter, of the rival lovers, of the compulsory marriage, and the attack made by the bride upon the hapless bridegroom, with the general catastrophe of the whole. All these things he recollected, just as he did before he took to his bed; but he literally recollected nothing else—not a single character woven by the romancer, not one of the many scenes and points of humor, nor anything with which he was himself connected, as the writer of the work." ("Life of Walter Scott," ch. 44.) —CARPENTER *Mental Physiology*, ch. 10, p. 443. (A., 1900.)

2146. MEMORY, MENDACITY OF—*Experience Compels to Reluctant Doubt.*—Yet, altho people in general are naturally disposed to be very confident about matters of recollection, reflective persons are pretty sure to find out, sooner or later, that they occasionally fall into errors of memory. It is not the philosopher who first hints at the mendacity of memory, but the "plain man" who takes careful note of what really happens in the world of his personal experience. Thus we hear persons quite innocent of speculative doubt qualifying an assertion made on personal recollection by the proviso, "unless my memory has played me false." And even less reflective persons, including many who pride themselves on their excellent memory, will, when sorely pressed, make a grudging admission that they may, after all, be in error.—SULLY *Illusions*, ch. 10, p. 233. (A., 1897.)

2147. MEMORY OF TOTALS—*"A Woman's Reason."*—Students of any branch of practical science, medicine, botany, conchology, etc., soon find that they are able to recognize a specimen without going through the processes which were at first necessary to come to an opinion—that is, they "see it at a glance," as it is called. Now, if a person always revives a whole as a whole, and never splits it up into components, these components will never occur to his mind. . . . An example of this is found in what is called "woman's reason"—that is, she feels sure that a certain thing is so and so

"because it is"; thus a critic might feel utterly unable to say why a certain picture was a forgery, but feel perfectly sure in his own mind that it was not genuine, the reason being that the picture in question did not possess the whole of the qualities of one painted by ———, and so would not revive the requisite impression.—ELDRIDGE-GREEN *Memory and Its Cultivation,* pt. ii, p. 257. (A., 1900.)

2148. MEMORY, PECULIARITIES OF —*Seeming Anomalies—Psychology Seeks to Explain Conditions of Its Action.*—For why should this absolute God-given faculty [of memory] retain so much better the events of yesterday than those of last year, and, best of all, those of an hour ago? Why, again, in old age should its grasp of childhood's events seem firmest? Why should illness and exhaustion enfeeble it? Why should repeating an experience strengthen our recollection of it? Why should drugs, fevers, asphyxia, and excitement resuscitate things long since forgotten? If we content ourselves with merely affirming that the faculty of memory is so peculiarly constituted by Nature as to exhibit just these oddities, we seem little the better for having invoked it, for our explanation becomes as complicated as that of the crude facts with which we started. Moreover there is something grotesque and irrational in the supposition that the soul is equipped with elementary powers of such an ingeniously intricate sort. Why should our memory cling more easily to the near than the remote? Why should it lose its grasp of proper sooner than of abstract names? Such peculiarities seem quite fantastic; and might, for aught we can see a priori, be the precise opposites of what they are. Evidently, then, the faculty does not exist absolutely, but works under conditions; and the quest of the conditions becomes the psychologist's most interesting task.—JAMES *Psychology,* vol. i, ch. 1, p. 2. (H. H. & Co., 1899.)

2149. MEMORY, REVIVAL OF—*Childhood's Early Impression Recalled.*—[The following incident was personally mentioned to the writer by the subject of it:] Several years ago, the Rev. S. Hansard, now rector of Bethnal Green, was doing clerical duty for a time at Hurstmonceaux, in Sussex; and while there he one day went over with a party of friends to Pevensey Castle, which he did not remember to have ever previously visited. As he approached the gateway, he became conscious of a very vivid impression of having seen it before; and he "seemed to himself to see" not only the gateway itself, but donkeys beneath the arch, and people on the top of it. His conviction that he must have visited the castle on some former occasion—altho he had neither the slightest remembrance of such a visit, nor any knowledge of having ever been in the neighborhood previously to his residence at Hurstmonceaux—made him inquire from his mother if she could throw any light on the matter. She at once informed him that, being in that part of the country when he was about eighteen months old, she had gone over with a large party and had taken him in the pannier of a donkey; that the elders of the party, having brought lunch with them, had eaten it on the roof of the gateway where they would have been seen from below, whilst he had been left on the ground with the attendants and donkeys. This case is remarkable for the vividness of the sensorial impression (it may be worth mentioning that Mr. Hansard has a decidedly artistic temperament), and for the reproduction of details which were not likely to have been brought up in conversation, even if he had happened to hear the visit itself mentioned as an event of his childhood, and of such mention he has no remembrance whatever.—CARPENTER *Mental Physiology,* ch. 10, p. 430. (A., 1900.)

2150. MEMORY, UNCONSCIOUS—*Automatic Action Gains in Rapidity and Ease—Separate Volitions Involve Delay—Language and Music.*—The more sure and perfect, indeed, memory becomes, the more unconscious it becomes; and, when an idea or mental state has been completely organized, it is revived without consciousness, and takes its part automatically in our mental operations, just as an habitual movement does in our bodily activity. We perceive in operation here the same law of organization of conscious acquisitions as unconscious power which we observed in the functions of the lower nerve-centers. A child, while learning to speak or read, has to remember the meaning of each word, [and] must tediously exercise its memory: but which of us finds it necessary to remember the meanings of the common words which we are daily using, as we must do those of a foreign language with which we are not very familiar? We do remember them, of course, but it is by an unconscious memory. In like manner a pupil, learning to play the pianoforte, is obliged to call to mind each note: but the skilful player goes through no such process of conscious remembrance: his ideas, like his movements, are automatic, and both so rapid as to surpass the rapidity of succession of conscious ideas and movements.—MAUDSLEY *Body and Mind,* lect. 1, p. 25. (A., 1898.)

2151. MERMAID, ORIGIN OF FABLE OF—*The Dugong—Truth Underlying Fiction.*—In the time of Alexander the Great and afterwards under the Seleucidæ, the ancient Greeks became acquainted with the northwestern part of India. Then and there they heard many strange tales, which, as usual (especially when two different races and languages are concerned), lost nothing in the telling. Among other things, they heard that the seas about Ceylon were peopled with mermaids. In this case, as in the other case of so many other wonderful tales, there was a certain amount of truth underlying the fiction; for those seas are peopled by

creatures [the dugong] (as big or bigger than human beings), which have a habit of raising themselves up vertically out of the water, when they present a very startling appearance to an unscientifically critical eye. Astonished travelers beheld beings with rounded, human-looking heads, showing their body down to the bust out of the water, displaying a pair of rounded prominent breasts, and not seldom holding a baby in their arms. After remaining some time in this attitude, they would suddenly dive, and then a tail like a fish's became exposed to view. Small wonder, then, that sailors should imagine they were beholding creatures half woman and half fish, for the vivacity of a sailor's imagination is proverbial.—MIVART *Types of Animal Life*, ch. 11, p. 303. (L. B. & Co., 1893.)

2152. METAL USED AS STONE—*Transition from Stone to Bronze.*—On the whole, tho it would seem that they [the American Indians] sometimes at any rate softened the metal by heat, we have not, I think, at present any sufficient evidence that the redskins were acquainted with the art of casting. This is the more surprising because, as Schoolcraft tells us, " in almost all the works lately opened there are heaps of coals and ashes, showing that fire had much to do with their operations." Thus, tho they were acquainted with metal, they did not know how to use it; and, as Professor Dana has well observed in a letter with which he has favored me, they may in one sense be said to have been in an age of stone, since they used the copper, not as metal, but as stone. This intermediate condition between an age of stone and one of metal is most interesting.—AVEBURY *Prehistoric Times*, ch. 8, p. 210. (A., 1900.)

2153. METALS, COMBUSTIBLE—*Burning of Iron and Zinc.*—The rusting of iron is, to all intents and purposes, the slow burning of iron. It develops heat, and, if the heat be preserved, a high temperature may be thus attained. The destruction of the first Atlantic cable was probably due to heat developed in this way. Other metals are still more combustible than iron. You may light strips of zinc in a candle flame and cause them to burn almost like strips of paper.—TYNDALL *Lectures on Light*, lect. 1, p. 5. (A., 1898.)

2154. METALS, DIFFUSION OR FLOWING OF—*Gold Sinking into Copper—Old Coins Buried Increase in Purity.*—It is well known to the jeweler that articles of copper, plated with gold, lose their brilliancy after a time, and that it can be restored by boiling them in ammonia; this effect is probably produced by the ammonia acting on the copper, and dissolving off its surface so as to expose the gold, which, by diffusion, has entered into the copper.

A slow diffusion of one metal through another probably takes place in cases of alloys. Silver coins, after having lain long in the earth, have been found covered with a salt of copper. This may be explained by supposing that the alloy of copper, at the surface of the coin, enters into combination with the carbonic acid of the soil, and being thus removed, its place is supplied by a diffusion from within, and in this way it is not improbable that a considerable portion of the alloy may be exhausted in the process of time; and the purity of the coin be considerably increased.—HENRY *Capillarity of Metals, Scientific Writings*, p. 229. (Sm. Inst., 1886.)

2155. —— —— *Silver Sinking into Pores of Copper—Recovery by Acid—Man of Science Instructs "Practical" Workmen.*—[To test his theory of metals] he [Henry] inquired of Mr. Cornelius, of Philadelphia, if in the course of his experience in working silver-plated copper in his extensive manufactory of lamps he had ever observed the silver to disappear from the copper when the metal was heated. The answer was that the silver always disappears when the plate is heated above a certain temperature, leaving a surface of copper exposed; and that it was generally believed by the workmen that the silver evaporates at this temperature.

Professor Henry suggested that the silver, instead of evaporating, merely sunk into the pores of the copper, and that by carefully removing the surface of the latter, by the action of an acid the silver would reappear. To verify this by experiment, Mr. Cornelius heated one end of a piece of thick plated copper to nearly the melting-point of the metal; the silver at this end disappeared, and when the metal was cleaned by a solution of dilute sulfuric acid, the end which had been heated presented a uniform surface of copper, whilst the other end exhibited its proper coating of silver. The unsilvered end of the plate was next placed, for a few minutes, in a solution of muriate of zinc, by which the exterior surface of copper was removed, and the surface of silver was again exposed. This method of recovering the silver (before the process of plating silver by galvanism came into use) would have been of much value to manufacturers of plated ware, since it often happened that valuable articles were spoiled, in the process of soldering, by heating them to a degree at which silver disappears.—HENRY *Capillarity of Metals, Scientific Writings*, p. 228. (Sm. Inst., 1886.)

2156. METALS THE GIFT OF VOLCANOES—*Brought from Depths of Earth.*—But it is not only the finely crystallized minerals and gems which we owe to volcanic action. The various metallic minerals have nearly all been brought from deep-seated portions of the earth's crust and deposited upon the sides of rock-fissures by the agency of the same volcanic forces. It is these forces which have, in the first instance, opened the cracks through the solid rock-masses; and, in the second place, have brought the metallic sulfids, oxids, and

salts—either in fusion, in solution, or in a vaporized condition—from the deep-seated masses within the earth, causing them to crystallize upon the sides of the fissures, and thus form those metallic lodes and veins which are within reach of our mining operations.—JUDD *Volcanoes*, ch. 5, p. 149. (A., 1899.)

2157. METAPHOR CONVEYS ESSENTIAL TRUTH—*All Language Metaphorical—Adaptation Best Expressed in Terms of Design.*—For what purpose are metaphors used? Is it not as a means of making plain to our own understandings the principle of things, and of tracing amid the varieties of phenomena the essential unities of Nature? In this sense all language is full of metaphor, being, indeed, composed of little else. . . . Accordingly, when naturalists, describing plants or animals, use the language of contrivance to describe the adaptations of function, they must use it because they feel it to be a help in the understanding of the facts. When, for example, we are told that flowers are constructed in a peculiar manner "in order that" they may catch the proboscides of moths or the backs of bees, and that this adaptation, again, is necessary "in order that" these insects should carry the fertilizing pollen from flower to flower, nothing more may be immediately intended by the writer than that all this elaborate mechanism does as a matter of fact attain this end, and that it may be fitly described "as if" it had been arranged "in order that" these things might happen. But this use of language is none the less an acknowledgment of the truth that the facts of Nature are best brought home and explained to the understanding, and to the intelligence of man, by stating them in terms of the relation which they obviously bear to the familiar operations of our own mind and spirit.—ARGYLL *Unity of Nature*, ch. 8, p. 174. (Burt.)

2158. METAPHOR, LANGUAGE OF, A NECESSITY OF SCIENCE—*Natural Selection—Elective Affinity.*—Others have objected that the term "selection" implies conscious choice in the animals which become modified; and it has even been urged that, as plants have no volition, natural selection is not applicable to them! In the literal sense of the word, no doubt, "natural selection" is a false term; but who ever objected to chemists speaking of the "elective affinities" of the various elements?—and yet an acid cannot strictly be said to "elect" the base with which it in preference combines. It has been said that I speak of "natural selection" as an active power or deity; but who objects to an author speaking of the "attraction of gravity" as "ruling" the movements of the planets? Every one knows what is meant and is implied by such metaphorical expressions, and they are almost necessary for brevity. So, again, it is difficult to avoid personifying the word "Nature"; but I mean by "Nature" only the aggregate action and product of many natural laws, and by "laws" the sequence of events as ascertained by us. —DARWIN *Origin of Species*, ch. 4, p. 74. (Burt.)

2159. METAPHYSICS, BAD OR GOOD?—*Positivism Also Metaphysical.*—Scientific men are accustomed to reckon such laws as the first law of motion among the surest possessions of pure intellect, and the faculty by which they are conceived among the noblest proofs of its energy and power. Positivism, on the contrary, regards such laws as mere "artifices" of thought, and the power by which they are conceived not as a strength, but as an "infirmity" of mind. I do not deny that the process by which these abstractions are attained is a metaphysical process—that is to say, they are purely mental conceptions. But the process which denies "reality" to these conceptions is also purely a metaphysical process, with this only difference, that it is bad metaphysics instead of good.—ARGYLL *Reign of Law*, ch. 2, p. 67. (Burt.)

2160. METEORITES, CELESTIAL SPACES FULL OF—*Millions Fall on the Earth.*—We may now remark that these meteors play a much more important part than we were formerly disposed to believe. A single night, a single hour, a single minute, does not pass without the fall of a star. The terrestrial globe sails in the midst of a space full of diverse corpuscles circulating in all directions—some in elliptical streams of various inclinations, others even in the plane of the ecliptic, as we see by the zodiacal light which extends from the sun to beyond the terrestrial orbit. By enumerating the number of shooting stars which are seen above a given horizon during the different nights of the year, calculating the number of similar horizons which would comprise the whole surface of the globe, and taking into account the directions of the shooting stars, the monthly variations, etc., an eminent American astronomer, Mr. Simon Newcomb, has demonstrated that no fewer than one hundred and forty-six thousand millions (146,000,000,000) of shooting stars fall per annum on the earth.—FLAMMARION *Popular Astronomy*, bk. v, ch. 4, p. 535. (A.)

2161. METEORITES, THEIR FALL RECORDED IN ANCIENT TIMES—The Greek natural philosophers, who were but little disposed to pursue observations, but evinced inexhaustible fertility of imagination in giving the most various interpretation of half-perceived facts, have, however, left some hypotheses regarding shooting stars and meteoric stones which strikingly accord with the views now almost universally admitted of the cosmical process of these phenomena. "Falling stars," says Plutarch, in his life of Lysander, "are, according to the opinion of some physicists, not eruptions of the ethereal fire extin-

guished in the air immediately after its ignition, nor yet an inflammatory combustion of the air, which is dissolved in large quantities in the upper regions of space, but these meteors are rather a fall of celestial bodies, which, in consequence of a certain intermission in the rotatory force, and by the impulse of some irregular movement, have been hurled down not only to the inhabited portions of the earth, but also beyond it into the great ocean, where we cannot find them." Diogenes of Apollonia expresses himself still more explicitly. According to his views, " Stars that are invisible, and, consequently, have no name, move in space together with those that are visible. These invisible stars frequently fall to the earth and are extinguished, as the stony star which fell burning at Egos Potamos."—HUMBOLDT *Cosmos*, vol. i, p. 133. (H., 1897.)

2162. METEORS, FALL OF, UPON THE SUN—*Cannot Supply His Heat.*—Now we may assume with great probability that very many more meteors fall upon the sun than upon the earth, and with greater velocity, too, and therefore give more heat. Yet the hypothesis that the entire amount of the sun's heat which is continually lost by radiation is made up by the fall of meteors, a hypothesis which was propounded by Mayer, and has been favorably adopted by several other physicists, is open, according to Sir W. Thomson's investigations, to objection; for, assuming it to hold, the mass of the sun should increase so rapidly that the consequences would have shown themselves in the accelerated motion of the planets. The entire loss of heat from the sun cannot at all events be produced in this way; at the most a portion, which, however, may not be inconsiderable.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 180. (L. G. & Co., 1898.)

2163. METEORS IN TRACK OF LOST COMET—To be lost is interesting, especially for a comet; but this, doubtless, was not enough, for it reserved for us a still more complete surprise. Its orbit intersects the terrestrial orbit at a point which the earth passes on November 27, 1872. Well, nothing more was thought about it; it was given up as hopeless, when, on the evening of November 27, 1872, there fell from the sky a veritable *rain of shooting stars.* The expression is not exaggerated; they fell in great flakes; lines of fire glided almost vertically in swarms and showers, here with dazzling globes of light, there with silent explosions recalling to mind those of rockets; and this rain lasted from seven o'clock in the evening till one o'clock next morning, the maximum being attained about nine o'clock. At the observatory of the Roman College 13,892 were counted; at Montealieri, 33,400; in England a single observer counted 10,579, etc. The total number has been estimated at a hundred and sixty thousand. They all came from the same point of the sky, situated near the beautiful star Gamma of Andromeda. . . . What was this shower of stars? Evidently—and this is not doubtful—the encounter with the earth of myriads of corpuscles moving in space along the orbit of Biela's comet. The comet itself, if it still existed, would have passed twelve weeks before. It was not, then, to speak correctly, the comet itself which we encountered, but perhaps a fraction of its decomposed parts, which, since the breaking-up of the comet in 1846, would be dispersed along its orbit behind the head of the comet.—FLAMMARION *Popular Astronomy*, bk. v, ch. 2, p. 500. (A.)

2164. METHOD, IMPORTANCE OF, IN PREPARATORY TRAINING—It does not matter so much what a scholar learns in the secondary school as how he learns. In other words, the method according to which the pupil is instructed and learns to think is decisive, as regards his preparatory training, of his capacity for future study.—ERDMANN *Ueber des Studium der Chemie*, p. 11. (Translated for *Scientific Side-Lights.*)

2165. METHOD OF ATTAINING SCIENTIFIC CONCLUSION—*Growth of Coral Only at Small Depths.*—The circumstance of a gradual change from a field of clean coral to a smooth sandy bottom is far more important in indicating the depth at which the larger kinds of coral flourish than almost any number of separate observations on the depth at which certain species have been dredged up. For we can understand the gradation only as a prolonged struggle against unfavorable conditions. If a person were to find the soil clothed with turf on the banks of a stream of water, but on going to some distance on one side of it he observed the blades of grass growing thinner and thinner with intervening patches of sand, until he entered a desert of sand, he would safely conclude, especially if changes of the same kind were noticed in other places, that the presence of the water was absolutely necessary to the formation of a thick bed of turf: so may we conclude, with the same feeling of certainty, that thick beds of coral are formed only at small depths beneath the surface of the sea.—DARWIN *Coral Reefs*, ch. 4, p. 111. (A., 1900.)

2166. METHOD OF SCIENCE VS. THAT OF RELIGION—In matters of science, light descends from the head to the heart; but in religion light ascends from the heart to the head. Only so far as we live in God can we understand him.—THOLUCK *Inscription in a Book.* (Translated for *Scientific Side-Lights.*)

2167. METHOD, THE VALUE OF—*Science Works to Definite Results.*—Two things are of particular remark in the discoveries in the Roman catacombs during the last thirty-eight years. First, they are the works of a single man; no one, this may be asserted, shares the fame of Giovanni

Battista de Rossi. And then, this is characteristic; accident has played no rôle here. They are the reward of science, conscious of its aim, well devised, according to definite rules. De Rossi never proceeds at random; he knows what he is doing, whither his way is leading, and always announces beforehand what he is going to find. Nothing illustrates better than the brilliant results of these excavations the value such labors derive from a good method.—MEYER *Die römischen Katakomben.* (Translated for *Scientific Side-Lights.)*

2168. MICROBES, INCONCEIVABLE MULTIPLICATION OF—*Death from Sting of a Fly.*—A man had died. Around the dead body, already disfigured, there was haste in order to withdraw from the living the spectacle of decomposition rapidly and profoundly taking place. Three days before, this man entered his home full of strength and of life, and a fly lighting upon his lip made an imperceptible prick—and behold, he was killed by a fly! No, the fly is a giant compared to what really produced this effect. It was the *bactéridée cherbonneuse* whose dipterous prick introduced the germ into the unfortunate victim. Two hours after the visit of the fly you might have counted two of these bacteria only in the blood of this man, four hours afterward it contained only four, six hours afterward, eight. The following day, when twenty-four hours had elapsed and he had banished from his mind all recollection of the unfortunate fly, he was still joyous and alert, but you might perhaps have clouded his gaiety by whispering in his ear that 4,996 of these bacteria were subsisting in his blood. You would have struck terror to his heart if the following day you had informed him that he now carried in his veins and arteries 16,000,000 of these germs. From the sixtieth to the seventy-second hour it would have been superfluous to try to comprehend that seventy-one milliards of bacteria had poisoned his vigorous constitution, and that by the seventy-fourth hour they had attained the enormous number of one hundred and forty-two milliards. . . . You are not surprised that the man was obliged to succumb. In fact there had taken place in his veins a magnificent struggle for which he was the stake.—COLTANCE *La Lutte pour l'Existence.* (Translated for *Scientific Side-Lights.)*

2169. MICRO-ORGANISMS FOSSIL IN CHALK—The slice of chalk presents a [very remarkable] appearance when placed under the microscope. The general mass of it is made up of very minute granules; but, embedded in this matrix, are innumerable bodies, some smaller and some larger, but, on a rough average, not more than a hundredth of an inch in diameter, having a well-defined shape and structure. A cubic inch of some specimens of chalk may contain hundreds of thousands of these bodies, compacted together with incalculable millions of the granules. . . . The chambered bodies are of various forms. One of the commonest is something like a badly grown raspberry, being formed of a number of nearly globular chambers of different sizes congregated together. It is called *Globigerina*, and some specimens of chalk consist of little else than *Globigerinæ* and granules. . . . It so happens that calcareous specimens exactly similar to the *Globigerinæ* of the chalk are being formed at the present moment by minute living creatures, which flourish in multitudes, literally more numerous than the sands of the seashore, over a large extent of that part of the earth's surface which is covered by the ocean.—HUXLEY *Lay Sermons*, serm. 9, pp. 178-180. (G. P. P., 1899.)

2170. MICRO-ORGANISMS FOUND LIVING IN OCEAN BED—In 1853, Lieutenant Brooke obtained mud from the bottom of the North Atlantic, between Newfoundland and the Azores, at a depth of more than 10,000 feet, or two miles, by the help of [his] sounding apparatus. The specimens were sent for examination to Ehrenberg, of Berlin, and to Bailey, of West Point, and those able microscopists found that this deep-sea mud was almost entirely composed of the skeletons of living organisms—the greater proportion of these being just like the *Globigerinæ* already known to occur in the chalk.—HUXLEY *Lay Sermons*, serm. 9, p. 181. (G. P. P., 1899.)

2171. MICROSCOPE, EARLY DISCOVERIES OF—*Fostered Belief in Spontaneous Generation.*—The discovery and improvement of the microscope, tho giving a death-blow to much that had been previously written and believed regarding spontaneous generation, brought also into view a world of life formed of individuals so minute—so close, as it seemed, to the ultimate particles of matter—as to suggest an easy passage from atoms to organisms. Animal and vegetable infusions exposed to the air were found clouded and crowded with creatures far beyond the reach of unaided vision, but perfectly visible to an eye strengthened by the microscope. With reference to their origin these organisms were called "Infusoria." Stagnant pools were found full of them, and the obvious difficulty of assigning a germinal origin to existences so minute furnished the precise condition necessary to give new play to the notion of heterogenesis or spontaneous generation.—TYNDALL *Fragments of Science*, vol. ii, ch. 13, p. 290. (A., 1900.)

2172. MICROSCOPE, SERVICE OF, TO SCIENCE—*Power of the Infinitely Little.*—As a matter of fact, there is no field of inquiry which has yielded such a large harvest to the truth-seeker of late years as that of microscopic research. There is scarcely a great discovery which has been made within the past decade in which our knowledge of the infinitely little, as shown forth by the microscope, has not figured most promi-

nently. Disease-germs and countless other lower forms of life have been traced out in their development and tracked to their origin. Living things, whose dimensions are to be estimated by the thousandth parts of inches, are as well known to us to-day as is the ostrich or the elephant. So far from the "little things" of the universe escaping our attention, I should be inclined to maintain that they largely monopolize science, to the exclusion of the big things. We are beginning to find out, in fact, that only by knowing something of the actions which proceed in the lower byways of life can existence in the main be understood at all.—ANDREW WILSON *Glimpses of Nature*, ch. 25, p. 80. (Hum., 1892.)

2173. MIGRATION, IRRATIONAL— *Blind Instinct of Progression of Lemmings.*—The lemming of Norway is a sort of vole, very celebrated on account of its sudden and marvelous migrations. When a conjuncture of favorable circumstances enables them to multiply to an enormous extent a migratory instinct becomes developed in them, whereby they are led to descend to lower-lying lands than those they normally frequent. They migrate slowly and intermittently, journeying only by night, and increasing frequently as they go. Their journey may last for three years before they reach the seacoast, according to the route they may happen to have followed. When they reach the coast they go on into the sea and so perish. As they journey along they are preyed upon by bears, wolves, foxes, dogs, wildcats, weasels, eagles, hawks, and owls. They are also destroyed by man, and even domestic animals, such as goats and reindeer, will spring upon and kill them. Numbers also die of disease, but they never turn back—they proceed ever onwards to their ultimate destination.—MIVART *Types of Animal Life*, ch. 12, p. 356. (L. B. & Co., 1893.)

2174. MIGRATION OF BIRDS, EXTENT OF—*Subsistence an Important Factor—Change of Diet of Non-migratory Birds.*—The extent of a bird's migration is, in most cases, dependent upon the nature of its food. Birds that are resident in one place throughout the year generally change their fare with the season, and apparently feed with equal relish on seeds or insects. Those that are dependent upon fruit must migrate far enough to find a supply of berries, while the insect-eaters are obliged to travel even farther south. Most of the migratory birds of our Western States pass the winter in Mexico. Our Eastern sparrows and our berry-eaters, like the robin and bluebird, winter from the Middle States to the Gulf coast, while the majority of our purely insectivorous species cross to Cuba and winter in the West Indies, or continue to Central America and even northern South America. Snipe and plover make the most extended migrations, some species breeding within the arctic circle and wintering along the coasts of Patagonia.—CHAPMAN *Bird-Life*, ch. 4, p. 49. (A., 1900.)

2175. MIGRATION OF PLANTS— *The Struggle for Life Lessened—Cross-fertilization Secured.*—The various devices by which plants are shifted from place to place are not merely to extend and multiply the species and reach a fertile soil, but to enable them to flee from the great number of their own kind and from their enemies among animals and parasitic plants. The adventurers among plants often meet with the best success, not because the seeds are larger, or stronger, or better, but because they find, for a time, more congenial surroundings. We must not overlook the fact, so well established, that one of the greatest points to be gained by plant migration is to enable different stocks of a species to be cross-fertilized, and thereby improved in vigor and productiveness.—BEAL *Seed Dispersal*, ch. 9, p. 85. (G. & Co., 1898.)

2176. MILDNESS OF THE EUROPEAN CLIMATE—*Heated Air from Tropics Descending.*—Gradually, however, as the upper stream, which rises from the equator and flows towards the poles, becomes chilled and dense, it sinks towards the earth; at the Peak of Teneriffe it has already sunk below the summit of the mountain. With the contrary wind blowing at the base, the traveler often finds the wind from the equator blowing strongly over the top. Farther north the equatorial wind sinks lower still, and finally reaches the surface of the earth. Europe, for the most part, is overflowed by this equatorial current. Here, in London, for eight or nine months in the year, southwesterly winds prevail. But mark what an influence this must have upon our climate. The moisture of the equatorial ocean comes to us endowed with potential energy; it comes, if you prefer the language, charged with latent heat. In our atmosphere condensation takes place, and the heat liberated is a main source of warmth to our climate. Were it not for the rotation of the earth we should have over us the hot, dry blasts of Africa; but, owing to this rotation, the wind which starts northward from the Gulf of Mexico is deflected to Europe. Europe is, therefore, the recipient of those stores of latent heat which were amassed in the western Atlantic. The British Isles come in for the greatest share of this moisture and heat, and this circumstance adds itself to that already dwelt upon—the high specific heat of water—to preserve our climate from extremes.—TYNDALL *Heat a Mode of Motion*, lect. 8, p. 212. (A., 1900.)

2177. MILK NORMALLY STERILE —*Can Be So Drawn—Yet Commonly Infested with Bacteria—Cleanliness the First Great Need.*—There are few liquids in general use which contain such enormous numbers of germs as milk. To begin with, milk

is in every physical way admirably adapted to be a favorable medium for bacteria. It is constituted of all the chief elements of the food upon which bacteria live. It is frequently at a temperature favorable to their growth. It is *par excellence* an absorptive fluid. . . . Yet, whilst this general fact is true, we must emphasize at the outset the possibility and practicability of securing absolutely pure sterile milk. Recently some milking was carried out under strict antiseptic precautions, with the above sterile result. The udder was thoroughly cleansed, the hands of the milker washed with corrosive sublimate and then pure water, the vessels which were to receive the milk had been carefully sterilized, and the whole process was carried out in strict cleanliness. The result was that the sample of milk remained sweet and good and contained no germs. It should be stated that the first flow of milk, washing out the milk-ducts of the udder, was rejected. This fact of the sterility of cleanly drawn milk is not a new one, and has been established by many bacteriologists. Milk, then, is normally a sterile secretion.—NEWMAN *Bacteria*, ch. 6, p. 180. (G. P. P., 1899.)

2178. MIMICRY, PROTECTIVE—*Brilliant, Inedible Moths Mimicked by Others.*—[A showy] protected group in the Eastern tropics is that of the beautiful day-flying moths forming the family *Agaristidæ*. These are usually adorned with the most brilliant colors or conspicuous markings, they fly slowly in forests among the butterflies and other diurnal insects, and their great abundance sufficiently indicates their possession of some distastefulness which saves them from attack. Under these conditions we may expect to find other moths which are not so protected imitating them, and this is the case. One of the common and wide-ranging species *(Ophthalmis lincea)*, found in the islands from Amboyna to New Ireland, is mimicked in a wonderful manner by one of the *Liparidæ*. . . . Both insects are black, with the apex of the fore wings ocher-colored, and the outer half of the hind wings bright orange.—WALLACE *Darwinism*, ch. 9, p. 167. (Hum.)

2179. ——— *Colors of Grouse and Ptarmigan.*—The close imitation in the plumage of these birds [the grouse and ptarmigan of Scotland] of the general tinting and mottling of the ground on which they lie and feed is apparent at a glance, and is best known to those who have tried to see grouse or ptarmigan when sitting, and when their position is indicated within a few feet or a few inches by the trembling nostrils and dilated eyeballs of a steady pointer dog. In the case of the common grouse, as the ground is nearly uniform in color throughout the year, the coloring of the bird is constant also. But in the case of the ptarmigan, it changes with the changing seasons. The pearly grays, which in summer match so exactly with the lichens of the mountain peaks, give place in winter to the pure white which matches not less perfectly with the wreaths of snow.—ARGYLL *Reign of Law*, ch. 4, p. 110. (Burt.)

2180. ——— *Dependent on Will—Moth Purposely Folds in His Brilliant Wings.*—There are some forms of mimicry which are wholly independent of any action on the part of the animals themselves, and this kind of mimicry is especially common in this class of insects. They are often made of the shape and of the color which are most like those of the surrounding objects in their habitat. They have nothing to do except to sit still, or perhaps to crouch. But there are other forms of mimicry in which the completeness of the deception depends on some cooperation of the animal's own will. This [the sudden disappearance of a brilliant Italian moth, apparently transformed into a withered leaf] was one of these. The splendid margins of the upper wings, with the peculiar shape and their shining color, had to be concealed; and so, by an effort which evidently required the exertion of special muscles, these margins were somehow folded down—reverted—covered up, and thus hidden out of sight. The remainder of the wings, or the under-surfaces which were now made uppermost, were so colored and so crumpled up that they imitated exactly the dried and withered leaves around.—ARGYLL *Unity of Nature*, ch. 3, p. 52. (Burt.)

2181. ——— *Grasshopper Resembling Wasp.*—A [special] case of mimicry not yet noticed by any naturalist is seen in [a species of] grasshopper common in La Plata *(Rhomalea speciosa*, of Thunberg). This is an extremely elegant insect: the head and thorax chocolate, with cream-colored markings; the abdomen steel-blue or purple, a color I have not seen in any other insects of this family. The fore wings have a protective coloring; the hind wings are bright red. When at rest, with the red and purple tints concealed, it is only a very pretty grasshopper, but the instant it takes wing it becomes the facsimile of a very common wasp of the genus *Pepris*. These wasps vary greatly in size, some being as large as the hornet; they are solitary, and feed on the honey of flowers and on fruit, and, besides being furnished with stings like other wasps—though their sting is not so venomous as in other genera—they also, when angry, emit a most abominable odor, and are thus doubly protected against their enemies. Their excessive tameness, slow flight, and indolent motions serve to show that they are not accustomed to be interfered with. All these strong-smelling wasps have steel-blue or purple bodies and bright red wings. So exactly does the *Rhomalea* grasshopper mimic the *Pepris* when flying that I have been deceived scores of times. I have even seen it on the leaves, and after

it has flown and settled once more I have gone to look at it again, to make sure that my eyes had not deceived me.—HUDSON *Naturalist in La Plata*, ch. 8, p. 127. (C. & H., 1895.)

2182. ——— ——— *Leaf-insects—Stick-insect.*—The well-known leaf-insects of Ceylon and of Java, species of *Phyllium*, are so wonderfully colored and veined, with leafy expansions on the legs and thorax, that not one person in ten can see them when resting on the food-plant close beneath their eyes. Others resemble pieces of stick with all the minutiæ of knots and branches, formed by the insects' legs, which are stuck out rigidly and unsymmetrically. I have often been unable to distinguish between one of these insects and a real piece of stick till I satisfied myself by touching it and found it to be alive.—WALLACE *Darwinism*, ch. 8, p. 138. (Hum.)

2183. ——— ——— *Sand-colored Lizard of Seashore.*—Of lizards there were many kinds, but only one (*Proctotretus multimaculatus*) remarkable from its habits. It lives on the bare sand near the seacoast, and from its mottled color, the brownish scales being speckled with white, yellowish red, and dirty blue, can hardly be distinguished from the surrounding surface. When frightened, it attempts to avoid discovery by feigning death, with outstretched legs, depressed body, and closed eyes; if further molested, it buries itself with great quickness in the loose sand. This lizard, from its flattened body and short legs, cannot run quickly. — DARWIN *Naturalist's Voyage around the World*, ch. 5, p. 97. (A., 1898.)

2184. ——— ——— *Stick-insect—Fly and Humblebee.*—The stick-insect is, perhaps, the most perfect example where resemblance to an inanimate object has been the result aimed at, so to speak, by Nature; the resemblance of the volucella fly to the humblebee, on which it is parasitical, is the most familiar example of one species growing like another to its own advantage, since only by means of its deceptive likeness to the humblebee is it able to penetrate into the nest with impunity.—HUDSON *Naturalist in La Plata*, ch. 8, p. 127. (C. & H., 1895.)

2185. MIND AND BODY, ON EARTH INSEPARABLE—*Magnetism and the Needle.*—In such a question as the connection of mind and body the potent method of removing the cause is not applicable. We cannot dissect the compound, man, into body apart and mind apart; we cannot remove mind so as to see if the body will vanish. We may remove the body, and in so doing we find that mind has disappeared; but the experiment is not conclusive: for in removing the body we remove our indicator of the mind, namely, the bodily manifestations—as if in testing for magnetism we should set aside the needle and other tokens of its presence.—BAIN *Mind and Body*, ch. 3, p. 5. (Hum., 1880.)

2186. MIND AND BRAIN — *Mental Power Not Measured by Size of Brain—Increase of Intellectual Force Geometrical.*—Comparing the increasing size of the brain with the increase in mental power, we are struck with the smallness of the one increase as compared with the other. An ordinary male human brain is 48 oz.; the brains of extraordinary men seldom reach Cuvier's figure, 64 oz. Now the intellectual force of the ordinary man is surpassed by Cuvier in a far higher ratio than this. Taking the mere memory, which is the basis of intellect, an ordinary man could not retain one-third or one-fourth, perhaps not one-tenth, of the facts stored up in the mind of a Cuvier. The comparison of animals with human beings would sustain a similar inference. There would be no exaggeration in saying that while size of brain increases in arithmetical proportion, intellectual range increases in geometrical proportion.—BAIN *Mind and Body*, ch. 3, p. 6. (Hum., 1880.)

2187. MIND AND MATTER, ALLIANCE OF—*Thought, Incapable of Extension, Allied with Extended Matter—Contrast and Mystery.*—This, then, as it appears to me, is the only real difficulty of the physical and mental relationship. There is an *alliance with matter*, with the object, or extended world; but the thing allied, the *mind proper*, has itself no extension, and cannot be joined in local union. Now, we have a difficulty in providing any form of language, any familiar analogy, suited to this unique conjunction; in comparison with all ordinary unions, it is a paradox or a contradiction. We understand union in the sense of local connection; here is a union where local connection is irrelevant, unsuitable, contradictory; for we cannot think of mind without putting ourselves out of the world of place. When, as in pure feeling—pleasure or pain—we change from the object attitude to the subject attitude we have undergone a change not to be expressed by place; the fact is not properly described by the transition from the *external* to the *internal*, for that is still a change in the region of the extended. The only adequate expression is a *change of state*: a change from the state of the extended cognition to a state of unextended cognition. By various theologians heaven has been spoken of as not a place, but a *state;* and this is the only phrase that I can find suitable to describe the vast tho familiar and easy transition from the material or extended to the immaterial or unextended side of our being.—BAIN *Mind and Body*, ch. 6, p. 34. (Hum., 1880.)

2188. MIND AND NATURE, INTERACTION OF—*Progress from Effect to Cause, Thence to New Effect.*—Our senses stand between these phenomena and the reasoning mind. We observe the fact, but are not satisfied with the mere act of observation; the fact must be accounted for—fitted into its position in the line of cause and effect.

Taking our facts from Nature, we transfer them to the domain of thought: look at them, compare them, observe their mutual relations and connections, and bringing them ever clearer before the mental eye, finally alight upon the cause which unites them. This is the last act of the mind, in this centripetal direction—in its progress from the multiplicity of facts to the central cause on which they depend. But, having guessed the cause, we are not yet contented. We set out from the center and travel in the other direction. If the guess be true, certain consequences must follow from it, and we appeal to the law and testimony of experiment whether the thing is so. Thus is the circuit of thought completed—from without inward, from multiplicity to unity, and from within outward, from unity to multiplicity.—TYNDALL *Fragments of Science*, ch. 11, p. 282. (A., 1897.)

2189. MIND, AN OBJECT OF SCIENTIFIC STUDY—*Improved Treatment of Insanity—Intelligent Investigation of Nervous Disease.*—The habit of viewing mind as an intangible entity or incorporeal essence, which science inherited from theology, prevented men from subjecting its phenomena to the same method of investigation as other natural phenomena: its disorders were thought to be an incomprehensible affliction and, in accordance with the theological notion, due to the presence of an evil spirit in the sufferer, or to the enslavement of the soul by sin, or to anything but their true cause—bodily disease. Consequently, the treatment of the insane was not in the hands of intelligent physicians, who aimed to apply the resources of medicine to the alleviation or cure of bodily illness, but was given up to coarse and ignorant jailers, whose savage cruelties will for all time to come be a great and ugly blot upon the enlightenment of the age which tolerated them. Matters are happily changed now. On all hands it is admitted that the manifestations of mind take place through the nervous system, and that its derangements are the result of nervous disease, amenable to the same method of investigation as other nervous diseases. Insanity has accordingly become a strictly medical study, and its treatment a branch of medical practise. Still, it is all too true that, notwithstanding we know much and are day by day learning more of the physiology of the nervous system, we are only on the threshold of the study of it as an instrument subserving mental function.—MAUDSLEY *Body and Mind*, lect. 1, p. 12. (A., 1898.)

2190. MIND A PART OF NATURE—*Mental Laws Are also Natural Laws.*—If the mind is so spoken of and represented as to suggest the idea of something apart from the general system of Nature, and if its laws of thought are looked upon as "forms" or molds into which, by some artificial arrangement or by some mechanical necessity, everything from outside must be squeezed and made to fit, then it will naturally occur to us to doubt whether conceptions cut out and manufactured under such conditions can be any trustworthy representation of the truth. Such, unfortunately, has been the mode of representation adopted by many philosophers, and such, accordingly, has been the result of their teaching. This is the great source of error in every form of the idealistic philosophy, but it is a source of error which can be perfectly eliminated, leaving untouched and undoubted the large body of truths which has made that philosophy attractive to so many powerful minds.—ARGYLL *Unity of Nature*, ch. 4, p. 89. (Burt.)

2191. MIND CONSCIOUS OF ITS OWN LIMITATIONS—*Limits of Opportunity Rather than of Power—Appetite Can Be Satisfied, but Mind or Spirit Cannot.*—Nothing, certainly, in the human mind is more wonderful than this—that it is conscious of its own limitations. For it is to be observed that such consciousness would be impossible if these limitations were in their nature absolute. The bars which we feel so much, and against which we so often beat in vain, are bars which could not be felt at all unless there were something in us which seeks a wider scope. It is as if these bars were a limit of opportunity rather than a boundary of power. No absolute limitation of mental faculty ever is, or ever could be, felt by the creatures whom it affects. Of this we have abundant evidence in the lower animals, and in those lower faculties of our own nature which are of like kind to theirs. Our bodily appetites can seek nothing beyond or beside the objects of their desire. To the attainment of these objects that desire is limited, and with this attainment it is satisfied. Moreover, when a bodily appetite is satisfied, it for the time ceases to exist, and may even be converted into nausea and disgust towards that which had been the object of pursuit. This is the necessary effect of a limitation which is absolute. But the case is very different with the appetites of the mind, and still more with the cravings of the spirit. Even in the purest physical investigations we are perpetually encountering some mental barrier through which we cannot break and over which we cannot see. And yet we know it and feel it to be a barrier and nothing more. We stop in front of it not because we are satisfied, but because it bars our way.—ARGYLL *Unity of Nature*, ch. 4, p. 76. (Burt.)

2192. MIND CONTROLLING BODY—*Confident Belief an Aid to Recovery.*—Perhaps we do not, as physicians, consider sufficiently the influence of mental states in the production of disease, and their importance as symptoms, or take all the advantage which we might take of them in our efforts to cure it. Quackery seems to have here got hold of a truth which legitimate

medicine fails to appreciate and use adequately. Assuredly the most successful physician is he who, inspiring the greatest confidence in his remedies, strengthens and exalts the imagination of his patient: if he orders a few drops of peppermint-water with the confident air of curing the disease, will he not really do more sometimes for the patient than one who treats him in the most approved scientific way, but without inspiring a conviction of recovery? Ceremonies, charms, gesticulations, amulets, and the like have in all ages and among all nations been greatly esteemed and largely used in the treatment of disease; and it may be speciously presumed that they have derived their power, not from any contract with the supernatural, but, as Bacon observes, by strengthening and exalting the imagination of him who used them. Entirely ignorant as we are, and probably ever shall be, of the nature of mind, groping feebly for the laws of its operation, we certainly cannot venture to set bounds to its power over those intimate and insensible molecular movements which are the basis of all our visible bodily functions, any more than we can justly venture to set bounds to its action in the vast and ever progressing evolution of Nature, of which all our thoughts and works are but a part.—MAUDSLEY *Body and Mind*, lect. 1, p. 38. (A., 1898.)

2193. MIND DOMINATED BY PRECONCEIVED IDEA—*Misreading of Words.*—A tendency to read a particular meaning into a word may lead to the misapprehension of the word. To give an illustration: I was lately reading the fifth volume of G. H. Lewes's "Problems of Life and Mind." In reading the first sentence of one of the sections, I again and again fell into the error of taking "The great Lagrange" for "The great Language." On glancing back I saw that the section was headed "On Language," and I at once recognized the cause of my error in the preexistence in my mind of the representative image of the word "language."—SULLY *Illusions*, ch. 9, p. 228. (A., 1897.)

2194. MIND INFINITELY VARIED—*Mental Qualities of Ants.*—Does it not seem as if Nature wants to play with our judgment by the variety and superiority of conceptions of which she offers an example, in the details as well as in the whole? We can only judge according to known facts, but Nature never imitates herself and has no need to imitate. The fecundity of understanding that has dictated these laws is not known to possess limits: each species has its habits, each individual its peculiar constitution. That is why we fall into errors without number, why our observations cause us to deviate in deciding which rules appear the most general. [This is observable in the case of] the ants, whose history furnishes so many examples of the insufficiency of our conjectures.—HUBER *Recherches sur les Mœurs des Fourmis indigènes*, p. 102. (Translated for *Scientific Side-Lights.*)

2195. MIND, IS IT LIMITED TO BRAIN?—*Intelligence in Reflex Movements.*—Is the brain the exclusive organ of mind? If it be so, to what category of functions shall we refer the reflex acts of the spinal cord, which take place independently of the brain, and which often achieve as definite an end, and seem to display as intelligent an aim, as any conscious act of volition?—MAUDSLEY *Body and Mind*, lect. 1, p. 15. (A., 1898.)

2196. MIND, LIMITATIONS OF—*Artistic and Scientific Genius Not Conjoined—Mastery in One Line Compatible with Ability in Many.*—A great mind may be great in many things, because the same kind of power may have numerous applications. The scientific mind of a high order is also the practical mind; it is the essence of reason in every mode of its manifestation—the true philosopher in conduct as well as in knowledge. On such a mind also a certain amount of artistic culture may be superinduced; its powers of acquisition may be extended so far. But the spontaneous, exuberant, imaginative flow, the artistic nature at the core, never was, cannot be, included in the same individual. Aristotle could not be also a tragic poet, nor Newton a third-rate portrait-painter. The cost of one of the two modes of intellectual greatness is all that can be borne by the most largely endowed personality; any appearances to the contrary are hollow and delusive.—BAIN app. to *Conservation of Energy* by STEWART, p. 431. (Hum., 1880.)

2197. MIND, LIMITS OF, UNKNOWN—*Worms Seeming to Exceed Ants in Intelligence.*—As worms are not guided by special instincts in each particular case, tho possessing a general instinct to plug up their burrows, and as chance is excluded, the next most probable conclusion seems to be that they try in many different ways to draw in objects, and at last succeed in some one way. But it is surprising that an animal so low in the scale as a worm should have the capacity for acting in this manner, as many higher animals have no such capacity. For instance, ants may be seen vainly trying to drag an object transversely to their course, which could be easily drawn longitudinally; tho after a time they generally act in a wiser manner.—DARWIN *Formation of Vegetable Mould*, ch. 2, p. 26. (Hum., 1887.)

2198. MIND, LITTLE DEVELOPMENT OF, WITHOUT SPEECH—*The Greatness of Mind Is Due to the Tongue.*—It is not too much to say that speech, if mental evolution is to come to anything or is to be worth anything, is a necessary condition. By it alone, in any degree worth naming, can the fruits of observation and experience of one generation be husbanded to form a new starting-point for a second, nor without it could there be any concerted action or social life. The greatness of the human mind,

after all, is due to the tongue, the material instrument of reason, and to language, the outward expression of the inner life.—DRUMMOND *Ascent of Man*, ch. 4, p. 152. (J. P., 1900.)

2199. MIND MUST BE TRAINED TO SOUND THINKING—*Science Cultivates Orderly Habits of Thought.*—The system of mind-gymnastics is one which is imperative on all ages and conditions. In no age can its advantages be more thoroughly understood than in this controversial epoch, when the oldest and most respected of ideas are ruthlessly deposed from their niches, and supplanted by new and advanced codes of opinion. To have our young trained to "think," and our elders to judiciously weigh and consider all the matters of life; to teach men and women how to use their reason; to enable them successfully to grapple with the great difficulties of trade and labor, of science and art, of morality and religion—such are the objects which this system of mind-training has in view. And the study of natural science accomplishes these great ends chiefly by inducing orderly habits of thought. The very essence of this study lies in the cultivation of the observant faculties, and in the true culture of the senses to appreciate, and, through appreciation, to understand and enjoy the objects which are set before the mind.—ANDREW WILSON *Science-Culture for the Masses*, p. 27. (Hum., 1888.)

2200. MIND, MYSTERIES OF, REVEALED IN MUSIC—It has always struck me as a mystery peculiarly interesting and wonderful that in the theory of music, in the physical and technical foundations of this art, which above all others seems to create in the mind the most immaterial, evanescent, and tender states of consciousness, incalculable and indescribable, that especially in this, the science of purest and strictest thought — mathematics — should prove itself preeminently productive. Thorough-bass is a kind of applied mathematics. As for musical intervals, divisions of time, and so forth, numerical fractions and even at times logarithms play a prominent part. Mathematics and music—the most glaring opposites possible in human thought! And yet they are connected, mutually sustained. It is as if they would demonstrate that hidden consensus of all activities of our mind which in the revelations of genius enables us to forefeel the unconscious utterances of an intelligence mysteriously active.—HELMHOLTZ *On the Physiological Causes of Harmony in Music (Popular Scientific Lectures*, p. 63.) (Translated for *Scientific Side-Lights.)*

2201. MIND NOT DEGRADED BY ASSOCIATION WITH THE ANIMAL BODY—*Electricity Not Materialized by Passing through Metal.*—So godlike a gift is intellect, so wondrous a thing is consciousness, that to link them with the animal world seems to trifle with the profoundest distinctions in the universe. Yet to associate these supersensuous things with the animal kingdom is not to identify them with the animal body. Electricity is linked with metal rods; it is not, therefore, metallic.—DRUMMOND *Ascent of Man*, ch. 4, p. 20. (J. P., 1900.)

2202. MIND OF MAN AND BEAST—*Resemblance in Action Indicates Mental Likeness—Monkeys and Children.*—At the Zoological Gardens one may sometimes see a handful of nuts divided between the monkeys inside the bars and the children outside, and it is instructive to notice how nearly both go through the same set of movements, looking, approaching, elbowing, grasping, cracking, munching, swallowing, holding out their hands for more. Up to this level the monkeys show all the mental likeness to man that their bodily likeness would lead us to expect. . . . The boy knows a nut by sight, wishes to renew the pleasant taste of former nuts, and directs his hands and mouth to grasp, crack, and eat. But here are complicated mental processes. Knowing a nut by sight, or having an idea of a nut, means that there are grouped together in the child's mind memories of a number of past sensations, which have so become connected by experience that a particular form and color, feel and weight, lead to the expectation of a particular flavor. Of what here takes place in the boy's mind we can judge, tho by no means clearly, from what we know about our own thoughts and what others have told us about theirs. What takes place in the monkeys' minds we can only guess by watching their actions, but these are so like the human as to be most readily explained by considering their brain-work also to be like the human, tho less clear and perfect. It seems as tho a beast's idea or thought of an object may be, as our own, a group of remembered sensations compacted into a whole.—TYLOR *Anthropology*, ch. 2, p. 48. (A., 1899.)

2203. MIND OF OBSERVER DETERMINES HIS VIEW OF NATURE—It may seem a rash attempt to endeavor to separate into its different elements the magic power exercised upon our minds by the physical world, since the character of the landscape and of every imposing scene in Nature depends so materially upon the mutual relation of the ideas and sentiments simultaneously excited in the mind of the observer. The powerful effect exercised by Nature springs, as it were, from the connection and unity of the impressions and emotions produced; and we can only trace their different sources by analyzing the individuality of objects and the diversity of forces. The richest and most varied elements for pursuing an analysis of this nature present themselves to the eyes of the traveler in the scenery of Southern Asia, in the Great Indian Archipelago, and more es-

pecially, too, in the New Continent, where the summits of the lofty Cordilleras penetrate the confines of the aerial ocean surrounding our globe, and where the same subterranean forces that once raised these mountain chains still shake them to their foundation and threaten their downfall.—HUMBOLDT *Cosmos*, vol. i, int., p. 27. (H., 1897.)

2204. MIND OVERWHELMED BY VAST PERIODS OF TIME—The chief cause of our natural unwillingness to admit that one species has given birth to other and distinct species is that we are always slow in admitting great changes of which we do not see the steps. The difficulty is the same as that felt by so many geologists, when Lyell first insisted that long lines of inland cliffs had been formed and great valleys excavated by the agencies which we still see at work. The mind cannot possibly grasp the full meaning of the term of even a million years; it cannot add up and perceive the full effects of many slight variations, accumulated during an almost infinite number of generations.—DARWIN *Origin of Species*, ch. 15, p. 497. (Burt.)

2205. MIND PREFERS CONCRETE TO ABSTRACT—I can consider the hand, the eye, the nose, each by itself abstracted or separated from the rest of the body. But then, whatever hand or eye I imagine, it must have some particular shape and color. Likewise the idea of man that I frame to myself must be either of a white, or a black, or a tawny, a straight, or a crooked, a tall, or a low, or a middle-sized man. I cannot by any effort of thought conceive the abstract idea above described. And it is equally impossible for me to form the abstract idea of motion distinct from the body moving, and which is neither swift nor slow, curvilinear nor rectilinear; and the like may be said of all other abstract general ideas whatsoever.—BERKELEY *Principles of Human Knowledge*, int., p. 178. (L., 1874.)

2206. MIND READILY REPRODUCES FAMILIAR IMPRESSIONS—*In Artist's Few Lines Spectator Sees the Face—Hence Ready Illusion.*—Another great fact that has come to light in the investigation of these illusions is that oft-recurring and familiar types of experience leave permanent dispositions in the mind. What has been frequently perceived is perceived more and more readily. It follows from this that the mind will be habitually disposed to form the corresponding mental images, and to interpret impressions by help of these. The range of artistic suggestion depends on this. A clever draftsman can indicate a face by a few rough touches, and this is due to the fact that the spectator's mind is so familiarized, through recurring experience and special interest, with the object, that it is ready to construct the requisite mental image at the slightest external suggestion. And hence the risk of hasty and illusory interpretation.—SULLY *Illusions*, ch. 5, p. 91. (A., 1897.)

2207. MIND REVEALED THROUGH MATTER—*Care of Body Important—Oxygen Ministers to Mental and Spiritual Life.*—Mind, like force, is known to us only through matter. Take, then, what hypothesis you will—consider matter as an instrument through which the insulated mind exercises its powers, or consider both as so inextricably mixed that they stand or fall together; from both points of view the care of the body is equally important. The morality of clean blood ought to be one of the best lessons taught us by our pastors and masters. The physical is the substratum of the spiritual, and this fact ought to give to the food we eat and to the air we breathe a transcendental significance. Boldly and truly writes Mr. Ruskin, "Whenever you throw your window wide open in the morning, you let in Athena, as wisdom and fresh air at the same instant; and whenever you draw a pure, long, full breath of right heaven, you take Athena into your heart, through your blood, and with the blood into thoughts of the brain." No higher value than this could be assigned to atmospheric oxygen.—TYNDALL *Hours of Exercise in the Alps*, ch. 25, p. 301. (A., 1898.)

2208. MIND, THE EVOLUTION OF—*Illustrated in a Savage—An Incalculable Creature to Civilized Man.*—No one should pronounce upon the evolution of mind till he has seen a savage. By this is not meant the show savage of an Australian town, or the quay Kafir of a South-African port, or the Reservation Indian of a Western State; but the savage as he is in reality, and as he may be seen to-day by any who care to look upon so weird a spectacle. No study from the life can compare with this in interest or in pathos, nor stir so many strange emotions in the mind of a thoughtful man. To sit with this incalculable creature in the heart of the great forest; to live with him in his natural home as the guest of Nature, to watch his ways and moods and try to resolve the ceaseless mystery of his thoughts—this, whether the existing savage represents the primitive savage or not, is to open one of the workshops of creation and behold the half-finished product from which humanity has been evolved.—DRUMMOND *Ascent of Man*, p. 142. (J. P., 1900.)

2209. MIND, THE MECHANICAL THEORY OF—*Ideas Like Bricks of the Structure.*—An influential school of psychology, seeking to avoid haziness of outline, has tried to make things appear more exact and scientific by making the analysis more sharp. The various fields of consciousness, according to this school, result from a definite number of perfectly definite elementary mental states, mechanically associated into a mosaic or chemically combined. According to some thinkers—Spencer, for example,

or Taine—these resolve themselves at last into little elementary psychic particles or atoms of "mind-stuff," out of which all the more immediately known mental states are said to be built up. Locke introduced this theory in a somewhat vague form. Simple "ideas" of sensation and reflection, as he called them, were for him the bricks of which our mental architecture is built up. . . . Whether it be true or false, it is at any rate only conjectural; and, for practical purposes, the more unpretending conception of the stream of consciousness, with its total waves or fields incessantly changing, will amply suffice.—JAMES *Talks to Teachers*, ch. 2, p. 19. (H. H. & Co., 1900.)

2210. MIND UNLIKE THE HUMAN UNKNOWN TO THE HUMAN—If it can be said with truth that "the universal mind is essentially other than the human mind," so that no recognizable relations can exist between them, then that universal mind is to us as if it were not.—ARGYLL *Reign of Law*, ch. 2, p. 63. (Burt.)

2211. MIND, UNTRAINED, PREFERS THE MARVELOUS TO THE TRUE—*Wonderful and Terrible Agencies Excite Superstition.*—It is not difficult to understand how false notions on the subject of volcanic action have come to be so generally prevalent. In the earlier stages of its development, the human mind is much more congenially employed in drinking in that which is marvelous than in searching for that which is true. It must be admitted, too, that the grand and striking phenomena displayed by volcanoes are especially calculated to inspire terror and to excite superstition, and such feelings must operate in preventing those close and accurate observations which alone can form the basis of scientific reasoning.—JUDD *Volcanoes*, ch. 1, p. 2. (A., 1899.)

2212. MIND WELL FURNISHED IS CAPABLE OF SUSTAINED ATTENTION—We can see why it is that what is called sustained attention is the easier, the richer in acquisitions and the fresher and more original the mind. In such minds, subjects bud and sprout and grow. At every moment, they please by a new consequence and rivet the attention afresh. But an intellect unfurnished with materials, stagnant, unoriginal, will hardly be likely to consider any subject long. A glance exhausts its possibilities of interest. Geniuses are commonly believed to excel other men in their power of sustained attention. In most of them, it is to be feared, the so-called "power" is of the passive sort. Their ideas coruscate, every subject branches infinitely before their fertile minds, and so for hours they may be rapt.—JAMES *Psychology*, vol. i, ch. 11, p. 423. (H. H. & Co., 1899.)

2213. MINERALS HELD INVISIBLE IN WATER—*Calcareous Substances Deposited by Boiling—Opposite Results of a Single Process.*—Spring-water and river-water that have passed through or over considerable distances in calcareous districts suffer change in boiling. The origin and nature of this change may be shown by an experiment as follows: Buy a pennyworth of lime-water from a druggist and procure a small glass tube of about quill size, or the stem of a fresh tobacco-pipe may be used. Half fill a small wine-glass with the lime-water, and blow through it by means of the tube or tobacco-pipe. Presently it will become turbid. Continue the blowing, and the turbidity will increase up to a certain degree of milkiness. Go on blowing with "commendable perseverance," and an inversion of effect will follow; the turbidity diminishes, and at last the water becomes clear again.

The chemistry of this is simple enough. From the lungs a mixture of nitrogen, oxygen, and carbonic acid is exhaled. The carbonic acid combines with the soluble lime, and forms a carbonate of lime, which is insoluble in mere water. But this carbonate of lime is to a certain extent soluble in water saturated with carbonic acid, and such saturation is effected by the continuation of blowing.

Take some lime-water that has been thus treated, place it in a clean glass flask, and boil it. After a short time the flask will be found incrusted with a thin film of something. This is the carbonate of lime which has been thrown down again by the action of boiling, which has driven off its solvent, the carbonic acid. This crust will effervesce if a little acid is added to it.—WILLIAMS *Chemistry of Cookery*, ch. 2, p. 10. (A., 1900.)

2214. MINERALS OF VESUVIUS—A great variety of minerals are found in the lavas of Vesuvius and Somma: augite, leucite, feldspar, mica, olivin, and sulfur are most abundant. It is an extraordinary fact that in an area of three square miles round Vesuvius a greater number of simple minerals have been found than in any spot of the same dimensions on the surface of the globe. Haüy enumerated only 380 species of simple minerals as known to him; and no less than eighty-two had been found on Vesuvius and in the tuffs on the flanks of Somma before the end of the year 1828. Many of these are peculiar to that locality. Some mineralogists have conjectured that the greater part of these were not of Vesuvian origin, but thrown up in fragments from some older formation, through which the gaseous explosions burst. But none of the older rocks in Italy or elsewhere contain such an assemblage of mineral products; and the hypothesis seems to have been prompted by a disinclination to admit that, in times so recent in the earth's history, the laboratory of Nature could have been so prolific in the creation of new and rare compounds. Had Vesuvius been a volcano of high antiquity, formed when Nature

> **Wanton'd as in her prime, and play'd at will**
> **Her virgin fancies,**

it would have been readily admitted that these, or a much greater variety of substances, had been sublimed in the crevices of lava, just as several new earthy and metallic compounds are known to have been produced by fumaroles, since the eruption of 1822.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 385. (A., 1854.)

2215. MINES, ANCIENT—*Trees of Great Age Growing on Excavated Earth.*—[A group of mining-works of very great antiquity] appears to have been first discovered in 1847 by Mr. Knapp, the agent of the Minnesota Mining Company. His observations have "brought to light ancient excavations of great extent, frequently from twenty-five to thirty feet deep, and scattered over an area of several miles. He counted three hundred and ninety-five annular rings on a hemlock-tree which grew on one of the mounds of earth thrown out of an ancient mine. Mr. Foster also notes the great size and age of a pine stump, which must have grown, flourished, and died since the works were deserted; and Mr. C. Whittesley not only refers to living trees upwards of three hundred years old, now flourishing in the gathered soil of the abandoned trenches, but adds, 'On the same spot there are the decayed trunks of a preceding generation or generations of trees that have arrived at maturity and fallen down from old age.'"—AVEBURY *Prehistoric Times*, ch. 8, p. 247. (A., 1900.)

2216. MINUTENESS INCONCEIVABLE—*Dimensions of Waves of Light—Microscopic Infinity.*—Whether, however, there are such things as waves of ether or not, there is something concerned in the phenomena of light which has definite dimensions, that have been measured with as much accuracy as the dimensions of astronomy, altho they are at the opposite extreme of the scale of magnitude. We represent these dimensions to our imagination as wave-lengths, that is, as the distances from crest to crest of our assumed ether-waves, and we shall find it difficult to think clearly upon the subject without the aid of this wave theory, and every student of physics will bear me out in the statement that, tho our theory may be a fantom of our scientific dreaming, these magnitudes must be the dimensions of something. Here they are:

Dimensions of Light-waves.

COLORS.	Number of waves in one inch.	Number of oscillations in one second.
Red	39,000	477,000,000,000,000
Orange	42,000	506,000,000,000,000
Yellow	44,000	535,000,000,000,000
Green	47,000	577,000,000,000,000
Blue	51,000	622,000,000,000,000
Indigo	54,000	658,000,000,000,000
Violet	57,000	689,000,000,000,000

. . . These values always create a smile with a popular audience, which makes it evident that, by those unfamiliar with the subject, they are looked upon as unreal, if not absurd. But this is a prejudice. In our universe the very small is as real as the very great; and if science in astronomy can measure distances so great that this same swift messenger, light, traveling 192,000 miles a second, requires years to cross them, we need not be surprised that, at the other end of the scale, it can measure magnitudes like these.—COOKE *New Chemistry*, lect. 1, p. 15. (A., 1899.)

2217. MIRACLE AN EXERCISE OF SUPERHUMAN POWER—Locke [in his "Discourse on Miracles"] recognizes the great truth that we can never know what is above Nature unless we know all that is within Nature. But he misses another truth, quite as important, that a miracle would still be a miracle even tho we did know the laws through which it was accomplished, provided those laws, tho not beyond human knowledge, were beyond human control. We might know the conditions necessary to the performance of a miracle, altho utterly unable to bring those conditions about. Yet a work performed by the bringing about of conditions which are out of human reach would certainly be a work attesting superhuman power.—ARGYLL *Reign of Law*, ch. 1, p. 15. (Burt.)

2218. MIRACLE, DIVINE AGENCY WITHOUT—*God Working in and through Natural Law.*—"These see the works of the Lord and his wonders in the deep. For he commandeth and raiseth the stormy wind which lifteth up the waves thereof" (Ps. cvii, 24-25).

He raises the tempest, not without the wind, but by the wind. In the one way it would have been a miracle, in the other way it is alike effectual, but without any change in the properties or laws of visible Nature—without what we commonly understand by a miracle.—CHALMERS *Astronomical Discourses*, suppl. disc. 2, p. 243. (R. Ct., 1848.)

2219. MIRAGE AMONG ICE-FLOES—*Cities and Towers of Cloudland.*—The truly wonderful scenery of Glacier Bay appeals most forcibly to the imagination during the lengthened twilights of summer. The latitude corresponds with that of the extreme north of Scotland. In summer the sun declines but a few degrees below the northern horizon, and the nights are sufficiently light to reveal the white-robed mountains in half-tones of the most delicate beauty. At such times the thousands of bergs and the broad ice-floes are transformed by the tricks of the mirage into shapes of the most remarkable description. Vast cities, with colonnades and ruined temples, towers and battlements, appear with marvelous realism where only a few moments before there was but a glassy plain of water studded with fragments of floating ice. Sheaf-like fountains and monumental shafts appear with such faithful imagery that one is more than half inclined

to yield to the delusion and believe that the apparitions are real. The weird beauty of the expanse of ice-freighted waters and the cold, stern, snow-covered mountains, as well as the lively anticipation of what is to come, make a sail on those northern waters, in brilliant weather, an event that thrills the fancy and leaves an indelible picture on the memory.—RUSSELL *Glaciers of North America*, ch. 6, p. 81. (G. & Co., 1897.)

2220. "MISCHIEF" IN CHILDREN— *Result of Constructive Instinct.*—Constructiveness is as genuine and irresistible an instinct in man as in the bee or the beaver. Whatever things are plastic to his hands, those things he must remodel into shapes of his own, and the result of the remodeling, however useless it may be, gives him more pleasure than the original thing. The mania of young children for breaking and pulling apart whatever is given them is more often the expression of a rudimentary constructive impulse than of a destructive one. "Blocks" are the playthings of which they are least apt to tire. Clothes, weapons, tools, habitations, and works of art are the result of the discoveries to which the plastic instinct leads, each individual starting where his forerunners left off, and tradition preserving all that once is gained.—JAMES *Psychology*, vol. ii, ch. 24, p. 426. (H. H. & Co., 1899.)

2221. MISER A LUNATIC — *Typical Hoard of Miser in Boston.*—In every lunatic asylum we find the collecting instinct developing itself in an equally absurd way. Certain patients will spend all their time picking pins from the floor and hoarding them. Others collect bits of thread, buttons, or rags, and prize them exceedingly. Now, "the miser" *par excellence* of the popular imagination and of melodrama, the monster of squalor and misanthropy, is simply one of these mentally deranged persons. . . . Even as I write, the morning paper gives an account of the emptying of a miser's den in Boston by the City Board of Health. What the owner hoarded is thus described:

"He gathered old newspapers, wrapping-paper, incapacitated umbrellas, canes, pieces of common wire, cast-off clothing, empty barrels, pieces of iron, old bones, battered tinware, fractured pots, and bushels of such miscellany as is to be found only at the city 'dump.' The empty barrels were filled, shelves were filled, every hole and corner was filled, and in order to make more storage-room, 'the hermit' covered his storeroom with a network of ropes, and hung the ropes as full as they could hold of his curious collections. There was nothing one could think of that wasn't in that room. As a wood-sawyer the old man had never thrown away a saw-blade or a wood-buck. The bucks were rheumatic and couldn't stand up, and the saw-blades were worn down to almost nothing in the middle. Some had been actually worn in two, but the ends were carefully saved and stored away. As a coal-heaver the old man had never cast off a worn-out basket, and there were dozens of the remains of the old things, patched up with canvas and rope-yarns, in the storeroom. There were at least two dozen old hats, fur, cloth, silk, and straw," etc.—JAMES *Psychology*, vol. ii, ch. 24, p. 424. (H. H. & Co., 1899.)

2222. MISINTERPRETATION, POPULAR, OF SCIENTIFIC PHENOMENON— I found an opinion prevalent among the sailors of the Spanish ships of the Pacific, that the age of the moon might be determined before the first quarter by looking at it through a piece of silk and counting the multiplied images. Here we have a phenomenon of diffraction observed through fine slits.—HUMBOLDT *Cosmos*, vol. iii, p. 129. (H., 1897.)

2223. MISSILES, METEORIC—*Air as Armor—A Soft but Sure Defense—The Ceaseless Rain of Meteors Shed Harmlessly Away.*—How, then, is it, it may be asked, that we never hear of even an accident from ordinary meteors, tho accidents from aerolites have not been altogether unknown? Here is this great vessel, the earth, sailing through space, and saluted every twenty-four hours by 400 millions of missiles, each flying towards her with many times the velocity of the swiftest cannon-ball. This goes on by day and by night, when living creatures are far from shelter as well as when they are protected in their various abodes; and yet the inhabitants of earth are perfectly safe from all danger. It is not merely that they have been so far fortunate as to escape hitherto, but that they really are as safe as tho the earth were protected by those three-feet armor-plates which will one day, we are told, defend our floating batteries.

The real protection of the earth is the air which surrounds her. Soft as the air is, the resistance it opposes to swift motion is very great. The swifter the motion the more effective is the resistance. In the case of the meteoric missiles falling on the earth the resistance is so great, owing to their enormous velocity, that they are consumed and presently vaporized in their rush through the upper parts of the air. Thus the air forms a perfect protection to our earth.—PROCTOR *Expanse of Heaven*, p. 164. (L. G. & Co., 1897.)

2224. ——— *Unseen Dangers—We Live Safely under an Annual Rain of One Hundred and Fifty Thousand Millions of Meteors.*—It is perhaps sufficiently startling to be told at the outset that nearly all shooting stars—nine hundred and ninety-nine out of every thousand, certainly—are missiles which rush towards the earth with a velocity far exceeding that of the swiftest cannon-ball. They are not missiles which miss their mark. They do not, as was once thought, merely graze our atmosphere. They come straight towards the earth, and many among them must make straight towards

living creatures on the earth. And tho they are for the most part small, they are by no means so small as to be unable to destroy life. Their swift motions make up for their smallness, and the actual momentum of some of the tiniest of these bodies is equivalent to the momentum of a cannon-ball. . . .

It has been estimated by Professor Simon Newcomb, of America, on grounds which are perfectly reliable, that including telescopic meteors (that is, meteors so small as only to be visible when they happen to pass across the field of view of a telescope) no less than 146,000 millions of meteoric bodies fall each year upon the earth. If one in a thousand struck a human being the inhabitants of the earth would be decimated in a single year.—PROCTOR *Expanse of Heaven*, p. 163. (L. G. & Co., 1897.)

2225. MISSILES OF DESTRUCTION —*Treasure Lavished for Defense—Expense of Modern Steel Guns.*—There are great steel rifles now in place on our coasts, with a bore of twelve inches, that will fire a shot twelve miles, and no steel armor used for ship protection could withstand such a shot. These guns are mounted on disappearing carriages. They are loaded and aimed behind the earthworks and then elevated and fired, after which they immediately disappear to a place of safety. The gunners are not exposed to the direct fire of the enemy, and the gun itself only for a short time. We are told that the United States has now under construction a still larger gun that will shoot still farther, and one shot well aimed will be sufficient to disable the strongest battle-ship that floats. This gun will weigh 140 tons when completed, and will have a bore of sixteen inches in diameter. Each shot will cost the government $1,000, but it will be much more economical to fire $1,000 shots than $500 shots if the former sinks a $2,000,000 ship each time it strikes the target, while the latter only makes an indentation in the armor, without piercing it. The present 12-inch-bore guns require 520 pounds of powder to fire them.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 31, p. 242. (F. H. & H., 1900.)

2226. MISSILES, USE OF, BY MONKEY—He [a brown capuchin monkey] became very angry and threw at her [a stranger who had laughed at him] everything he could lay his hands on; first the nut, then the hammer, then a coffee-pot which he seized out of the grate, and, lastly, all his own shawls. He throws things with great force and precision by holding them in both hands, and extending his long arms well back over his head before projecting the missile, standing erect the while.

There is continual war between him and Sharp [a small terrier], but they both seem to have a certain mutual respect for each other. The dog makes snatches at nuts, etc., and runs away with them beyond the reach of his chain, and the monkey catches at the dog, but seems afraid to hold him or hurt him. He, however, pelts him with nuts or bits of carrot, and chatters at him.

[At a later date:] When he throws things at people now he first runs up the bars of the clothes-horse; he seems to have found out that people do not much care for having things thrown at their feet, and he is not strong enough to throw such heavy objects as a poker or a hammer at people's heads; he therefore mounts to a level with his enemy's head, and thus succeeds in sending his missile to a greater height and also to a greater distance.—ROMANES *Animal Intelligence (extracts from diary of author's sister)*, ch. 17, pp. 485, 490. (A., 1899.)

2227. MISTLETOE AS A PARASITE —*Idle Appropriation of Stores Gathered by Another Organism.*—I have before me a piece of an apple-tree's branch. It has been cut through dexterously enough, and the relations of a sprig of mistletoe which has attached itself to the bough are rendered clear and distinct. The mistletoe is not merely a lodger on the apple; it is a boarder likewise. Like certain dissatisfied tenants nowadays, it insists on holding to its landlord, while it declines to pay rent in any shape or form. Into the substance of the apple-tree the parasite has dipped its sucking roots, and a whole array of these roots is seen in my section, serving to drink up into the mistletoe-plant the sap which the apple-tree has made and elaborated for its own use. There is no intermingling here of parasite and prey. It is an attachment pure and simple for purposes of lodgment and food.—WILSON *Glimpses of Nature*, ch. 21, p. 69. (Hum., 1892.)

2228. MIXTURE VS. UNION, DIFFERENCE ILLUSTRATED—*Expansive Force of Gunpowder—Air Not Necessary for Explosion.*—Gunpowder before it is burned is simply a mixture; when it is burned the carbon unites with the oxygen of the niter, creating carbon dioxid as well as setting free a large amount of nitrogen gas. One cubic inch of gunpowder will produce 207 cubic inches of gas at ordinary atmospheric pressure and when the temperature is only 60° F. Of course when the gunpowder is burned in a confined space the gases are intensely heated and will therefore occupy a much larger space than at a lower temperature. By keeping the fact in mind that powder, in its gaseous state, occupies so much more room than it does in the solid state, the reader can readily understand where the gunpowder gets its energy when it is burned. Its gases must expand instantly and enormously. Gunpowder does not require air to explode it, because the niter that is in the mixture is very rich in oxygen, so that when it is heated to the point of ignition there is an instantaneous union between the carbon of the charcoal and the oxygen

of the niter, producing a gas.—ELISHA GRAY *Nature's Miracles,* vol. ii, ch. 27, p. 221. (F. H. & H., 1900.)

2229. MOBILITY OF ATTENTION IN CHILDHOOD—*Lack of Organized Activities—Preoccupation by Immediate Sensation.*—Sensitiveness to immediately exciting sensorial stimuli characterizes the attention of childhood and youth. In mature age we have generally selected those stimuli which are connected with one or more so-called permanent interests, and our attention has grown irresponsive to the rest. But childhood is characterized by great active energy, and has few organized interests by which to meet new impressions and decide whether they are worthy of notice or not, and the consequence is that extreme mobility of the attention with which we are all familiar in children, and which makes their first lessons such rough affairs. Any strong sensation whatever produces accommodation of the organs which perceive it, and absolute oblivion, for the time being, of the task in hand. This reflex and passive character of the attention, which, as a French writer says, makes the child seem to belong less to himself than to every object which happens to catch his notice, is the first thing which the teacher must overcome. It never is overcome in some people, whose work, to the end of life, gets done in the interstices of their mind-wandering.—JAMES *Psychology,* vol. i, ch. 11, p. 417. (H. H. & Co., 1899.)

2230. MODIFICATION OF ANIMAL STRUCTURES—*Adaptation to New Conditions—Changes of Form in Ocean Depths.*—The abysmal fauna is not, in fact, remarkable for possessing a large number of primitive or archaic forms. It is mainly composed of a number of species belonging to the families and genera of our shallow-water fauna that have, from time to time, migrated into greater depths and become modified in their structure in accordance with the extraordinary conditions of their new habitat. There is very good reason to believe that this migration has been going on from time immemorial, and consequently we find a few forms typical of the bygone times, left to struggle for existence with the more recent immigrants from shallow waters.—HICKSON *Fauna of the Deep Sea,* ch. 5, p. 87. (A., 1894.)

2231. MODIFICATION OF PARTS IN ORCHIDS—*Evidence of Gradual Change—Adaptation by Alteration of Function.*—It is interesting to look at one of the magnificent exotic species [of orchids] or, indeed, at one of our humblest forms, and observe how profoundly it has been modified, as compared with all ordinary flowers, with its great labellum, formed of one petal and two petaloid stamens—with its singular pollen-masses . . . —with its column formed of seven cohering organs, of which three alone perform their proper function, namely, one anther and two generally confluent stigmas—with the third stigma modified into the rostellum and incapable of being fertilized—and with three of the anthers no longer functionally active, but serving either to protect the pollen of the fertile anther, or to strengthen the column, or existing as mere rudiments, or entirely suppressed. What an amount of modification, cohesion, abortion, and change of function do we here see! Yet hidden in that column, with its surrounding petals and sepals, we know that there are fifteen groups of vessels, arranged three within three, in alternate order, which probably have been preserved to the present time from being developed at a very early period of growth, before the shape or existence of any part of the flower is of importance for the well-being of the plant.—DARWIN *Fertilization of Orchids,* ch. 8, p. 245. (A., 1898.)

2232. MODIFICATIONS WROUGHT BY MAN ON THE EARTH—*Limits of Human Power.*—The modifications in the system of which man is the instrument do not, perhaps, constitute so great a deviation from previous analogy as we usually imagine; we often, for example, form an exaggerated estimate of the extent of our power in extirpating some of the inferior animals, and causing others to multiply, a power which is circumscribed within certain limits, and which, in all likelihood, is by no means exclusively exerted by our species. The growth of human population cannot take place without diminishing the numbers or causing the entire destruction of many animals. The larger beasts of prey, in particular, give way before us; but other quadrupeds of smaller size, and innumerable birds, insects, and plants, which are inimical to our interests, increase in spite of us, some attacking our food, others our raiment and persons, and others interfering with our agricultural and horticultural labors. We behold the rich harvest which we have raised by the sweat of our brow devoured by myriads of insects, and are often as incapable of arresting their depredations as of staying the shock of an earthquake or the course of a stream of lava.—LYELL *Principles of Geology,* bk. i, ch. 9, p. 150.

2233. MOLECULES OF GASES—*Distance and Size Infinitely Small—Molecular Theory—Infinite Minuteness Overwhelms the Mind.*—The very remarkable properties of gases, their apparently unlimited elasticity and indefinite powers of expansion, were very difficult to explain on any theory of their molecules being subject to such attractive and repulsive forces as seem to exist in other states of matter. A consideration of these properties, together with the power of diffusion by which gases of very different densities form a perfect mixture when in contact, and the fact that by the application of heat almost all liquids and

many solids can be changed into gases, led to the conception that they owed their peculiar properties to their molecules being in a state of intensely rapid motion in all directions. On this theory the molecules are very far apart in proportion to their size, and are continually coming in contact with each other. Owing to their perfect elasticity they rebound without loss of motion or energy, and their continual impact against the sides of the vessel containing them is what gives to gases their great expansibility. From a study of these various properties it has been calculated that at ordinary temperatures there are some hundreds of trillions of molecules in a cubic inch of gas, and that these collide with each other eight thousand millions of times in a second. The average length of the path between two collisions of a molecule is less than the two-hundred-thousandth of an inch, yet this small length is supposed to be at least a hundred times as great as the diameter of each molecule.—WALLACE *The Wonderful Century*, ch. 7, p. 54. (D. M. & Co., 1899.)

2234. MOLECULES OF IRON MAGNETIC—*Magnetism an Inherent Property—Ampère's Theory.*—Iron and steel have a peculiar property called magnetism. It is an attraction in many ways unlike the attraction of cohesion or the attraction of gravitation. It is very certain that magnetism is an inherent property of the molecules of iron and steel, and, to a small degree, other forms of matter. That is to say, the molecules are little natural magnets of themselves. It is as unnecessary to inquire why they are magnets as it is to inquire why the molecules of all ordinary substances possess the attraction of cohesion. The one is as easy to explain as the other. People of all ages have insisted upon making a greater mystery of all electrical and magnetic phenomena than they do of other natural forces. Ampère's theory is that electric currents are flowing around the molecules which render them magnetic; but it is just as easy to suppose that magnetism is an inherent quality of the molecule. (The word "molecule" is here used as referring to the smallest particle of iron.)

These little molecular magnets, so small that 100,000 million million million of them can be put into a cubic inch of space, have their attractions satisfied by forming into little molecular rings, with their unlike poles together, so that when the iron is in a natural or unmagnetized condition it does not attract other iron.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 4, p. 25. (F. H. & H., 1900.)

2235. MONKEY TRAINED TO GATHER NUTS—*Limited Intelligence—Unwilling Obedience.*—The orang-outan, indeed, which for its resemblance in form to man, and apparently for no other good reason, has been assumed by Lamarck to be the most perfect of the inferior animals has been tamed by the savages of Borneo and made to climb lofty trees, and to bring down the fruit. But he is said to yield to his masters an unwilling obedience, and to be held in subjection only by severe discipline. We know nothing of the faculties of this animal which can suggest the idea that it rivals the elephant in intelligence, much less anything which can countenance the dreams of those who have fancied that it might have been transmuted into the "dominant race." One of the baboons of Sumatra *(Simia carpolegus)* appears to be more docile, and is frequently trained by the inhabitants to ascend trees for the purpose of gathering coconuts, a service in which the animal is very expert. He selects, says Sir Stamford Raffles, the ripe nuts with great judgment, and pulls no more than he is ordered. The capuchin and cacajao monkeys are, according to Humboldt, taught to ascend trees in the same manner, and to throw down fruit, on the banks of the lower Orinoco.—LYELL *Principles of Geology*, bk. iii, ch. 35, p. 599. (A., 1854.)

2236. MONOTONY OF SOUTH-AMERICAN PLAINS—*Birds Subdued by Nature's Silence.*—The general aspect of the plain is monotonous, and in spite of the unobstructed view and the unfailing verdure and sunshine, somewhat melancholy, altho never somber; and doubtless the depressed and melancholy feeling the pampa inspires in those who are unfamiliar with it is due in a great measure to the paucity of life and to the profound silence. The wind, as may well be imagined on that extensive level area, is seldom at rest; there, as in the forest, it is a "bard of many breathings," and the strings it breathes upon give out an endless variety of sorrowful sounds, from the sharp, fitful sibilations of the dry, wiry grasses on the barren places to the long, mysterious moans that swell and die in the tall, polished rushes of the marsh. It is also curious to note that, with a few exceptions, the resident birds are comparatively very silent, even those belonging to groups which elsewhere are highly loquacious. . . . As a rule, their voices are strangely subdued; Nature's silence has infected them, and they have become silent by habit.—HUDSON *Naturalist in La Plata*, ch. 1, p. 8. (C. & H., 1895.)

2237. MONSTERS OF SENTIMENTALITY—*Woman Weeping in Theater—Coachman Freezing Outside—Resolute Doing to Keep Character Real (Matt. vii, 24-29).*—All goods are disguised by the vulgarity of their concomitants in this workaday world; but woe to him who can only recognize them when he thinks them in their pure and abstract form! The habit of excessive novel-reading and theatergoing will produce true monsters in this line. The weeping of a Russian lady over the fictitious personages in the play, while her coachman is freezing to death on his seat outside, is the

sort of thing that everywhere happens on a less glaring scale. Even the habit of excessive indulgence in music, for those who are neither performers themselves nor musically gifted enough to take it in a purely intellectual way, has probably a relaxing effect upon the character. One becomes filled with emotions which habitually pass without prompting to any deed, and so the inertly sentimental condition is kept up. The remedy would be never to suffer one's self to have an emotion at a concert without expressing it afterwards in some active way. Let the expression be the least thing in the world—speaking genially to one's aunt, or giving up one's seat in a horse-car, if nothing more heroic offers—but let it not fail to take place.—JAMES *Psychology*, vol. ii, ch. 4, p. 125. (H. H. & Co., 1899.)

2238. MONUMENTS CONFIRMING HISTORIAN'S ACCURACY—*Herodotus and Persian Impostor.*—The way in which modern discoveries have come in to confirm his [Herodotus's] statements justifies us in relying on ancient historians when, like him, they are careful to distinguish mere legend or hearsay from what they have themselves inquired into. Thus Herodotus tells the strange story of the impostor who passed himself off as Smerdis, and sat on the throne of Persia till he was detected by his cropped ears, and Darius slew him. When, a few years ago, the cuneiform characters of the inscription sculptured in a high wall of rock near Behistan in Persia were deciphered, it proved to be the very record set up by Darius the king in the three languages of the land, and it matches the account given by Herodotus closely enough to show what a real grasp he had of the course of events in Persia a century before his time.—TYLOR *Anthropology*, ch. 15, p. 386. (A., 1899.)

2239. MOON, PHASES OF, THE BASIS OF THE CALENDAR—"*He Appointeth the Moon for Seasons*" (*Ps. civ, 19*).—The proper motion of the moon from west to east, and the succession of phases, may be considered as the most ancient facts of observation of the sky, and as the first basis of measurement of time and of the calendar.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 1, p. 95. (A.)

2240. MOON, SUPPOSED PERNICIOUS EFFECT OF—*Blindness Ascribed to Moonbeams—The Chill of Celestial Space.*—My face [when attempting to sleep at night on the Weisshorn] was turned towards the moon until it became so chilled that I was forced to protect it by a light handkerchief. The power of blinding the eyes is ascribed to the moonbeams, but the real mischief is that produced by radiation from the eyes into clear space, and the inflammation consequent upon the chill.—TYNDALL *Hours of Exercise in the Alps*, ch. 9, p. 96. (A., 1898.)

2241. MORALITY AND SCIENCE—*Evolution as Prophecy—Progress in Future as in Past.*—The doctrine of evolution presents its greatest attractiveness when viewed, not merely in its scientific aspect, as the highest form of the intellectual interpretation of Nature, but in its moral bearings, as one which leads man ever onwards and upwards, and encourages his brightest anticipations of the ultimate triumph of truth over error, of knowledge over ignorance, of right over wrong, of good over evil, thus claiming the earnest advocacy of every one who accepts it as scientifically true.—CARPENTER *Nature and Man*, lect. 14, p. 408. (A., 1889.)

2242. MORALITY DEMANDS ACTION IN LINE OF GREATEST RESISTANCE—*Ease of Following Propensities—A Struggle for Ideals.*—When outer forces impinge upon a body, we say that the resultant motion is in the line of least resistance, or of greatest traction. But it is a curious fact that our spontaneous language never speaks of volition with effort in this way. . . . He who under the surgeon's knife represses cries of pain, or he who exposes himself to social obloquy for duty's sake, feels as if he were following the line of greatest temporary resistance. He speaks of conquering and overcoming his impulses and temptations.

But the sluggard, the drunkard, the coward, never talk of their conduct in that way or say they resist their energy, overcome their sobriety, conquer their courage, and so forth. If in general we class all springs of action as propensities on the one hand and ideals on the other, the sensualist never says of his behavior that it results from a victory over his ideals, but the moralist always speaks of his as a victory over his propensities. The sensualist uses terms of inactivity, says he forgets his ideals, is deaf to duty, and so forth: which terms seem to imply that the ideal motives *per se* can be annulled without energy or effort, and that the strongest mere traction lies in the line of the propensities. . . . And if a brief definition of ideal or moral action were required, none could be given which would better fit the appearances than this: It is action in the line of the greatest resistance. —JAMES *Psychology*, vol. ii, ch. 26, p. 548. (H. H. & Co., 1899.)

2243. MORALITY DISTINCTIVE—*Contrasted with Habit and Expediency.*—The difference between the *habitual*, the *prudential*, and the *moral* aspects of the very same action may be made apparent by a very simple illustration: We will suppose that a man has been accustomed to take a ride every day at a particular hour; his whole nature so accommodates itself to the habit that he feels both mentally and physically uncomfortable at any interruption to the usual rhythm. But suppose that, just as the appointed hour comes round, the sky

becomes overcast, threatening the rider with a drenching if he perseveres in his intention; his decision will then be founded on a prudential consideration of the relative probabilities of his escaping or of his being exposed to the shower, and of how far the enjoyment he may derive from his ride is likely to be replaced by the discomfort of a thorough wetting. But suppose, further, that instead of taking a mere pleasure ride, a medical man is about to set forth on a professional visit to a patient whose condition requires his aid; a new motive is thus introduced, which alters the condition of the whole question, making it no longer one of prudence only, but one of morality.—CARPENTER *Mental Physiology*, ch. 9, p. 416. (A., 1900.)

2244. MORALITY, ELEMENTAL, OF LOWER ANIMALS—*"Man the God of the Dog."*—Of these elementary moral feelings, those of the lower animals which associate most closely with man are obviously capable. The sense of duty towards a being of a higher nature, which shows itself in the actions of the young child towards its parent or nurse, long before any ideational comprehension of it can have been attained, is exactly paralleled by that of the dog or the horse towards its master. "Man," as Burns truly says, "is the god of the dog."—CARPENTER *Mental Physiology*, bk. i, ch. 5, § 190, p. 212. (A., 1900.)

2245. MORALITY INDEPENDENT OF REWARD OR PUNISHMENT—It is true, indeed, that these rightful authorities, which are enthroned in Nature, are fortified by power to enforce their commands, and to punish violations of the duty of obedience. It is true, therefore, that from the first moments of our existence the sense of obligation is reenforced by the fear of punishment. And yet we know, both as a matter of internal consciousness, and as a matter of familiar observation in others, that this sense of obligation is not only separable from the fear of punishment, but is even sharply contradistinguished from it. Not only is the sense of obligation powerful in cases where the fear of punishment is impossible, but in direct proportion as the fear of punishment mixes or prevails, the moral character of an act otherwise good is diminished or destroyed. The fear of punishment and the hope of reward are, indeed, auxiliary forces which cannot be dispensed with in society. But we feel that complete goodness and perfect virtue would dispense with them altogether.—ARGYLL *Unity of Nature*, ch. 9, p. 211. (Burt.)

2246. MORALITY IN INTENTION—There can be no moral character in any action, so far as the individual actor is concerned, apart from the meaning and intention of the actor. The very same deed may be good or, on the contrary, devilishly bad, according to the inspiring motive of him who does it. The giving of a cup of cold water to assuage suffering, and the giving it to prolong life in order that greater suffering may be endured, are the same outward deeds, but are exactly opposite in moral character.—ARGYLL *Unity of Nature*, ch. 9, p. 197. (Burt.)

2247. MORALITY NOT A MATTER OF SEX—*Pugnacity of Men and Women.*—Tho the female sex is often said to have less pugnacity than the male, the difference seems connected more with the extent of the motor consequences of the impulse than with its frequency. Women take offense and get angry, if anything, more easily than men, but their anger is inhibited by fear and other principles of their nature from expressing itself in blows.—JAMES *Psychology*, vol. ii, ch. 24, p. 415. (H. H. & Co., 1899.)

2248. MORALS, FOUNDATION OF—*Imaginary Laws of Nature—Rousseau—The French Revolution.*—M. Comte was right in affirming that the prevailing schools of moral and political speculation, when not theological, have been metaphysical. They affirmed that moral rules, and even political institutions, were not means to an end, the general good, but corollaries evolved from the conception of natural rights. This was especially the case in all the countries in which the ideas of publicists were the offspring of the Roman law. The legislators of opinion on these subjects, when not theologians, were lawyers: and the Continental lawyers followed the Roman jurists, who followed the Greek metaphysicians, in acknowledging as the ultimate source of right and wrong in morals, and consequently in institutions, the imaginary law of the imaginary being Nature. The first systematizers of morals in Christian Europe, on any other than a purely theological basis, the writers on international law, reasoned wholly from these premises, and transmitted them to a long line of successors. This mode of thought reached its culmination in Rousseau, in whose hands it became as powerful an instrument for destroying the past as it was impotent for directing the future. The complete victory which this philosophy gained in speculation over the old doctrines was temporarily followed by an equally complete practical triumph, the French Revolution; when, having had, for the first time, a full opportunity of developing its tendencies, and showing what it could not do, it failed so conspicuously as to determine a partial reaction to the doctrines of feudalism and Catholicism.—MILL *Positive Philosophy of Auguste Comte*, p. 64. (H. H. & Co., 1887.)

2249. MOTH ASSUMES INSTANT INVISIBILITY—*Protective Mimicry.*—It was in the beautiful Riviera, where insect life continues much more active at that season than it can be anywhere in the north of Europe. But even there, altho bees are busy during the greater part of winter, and some of our own *Sylviadæ* find an abundant living

throughout the season, the order of the *Lepidoptera* are generally dormant. I was surprised, therefore, late in the month of November, to see a large insect of this order come from above the olive-trees overhead with the wild, dashing flight of the larger moths. Attracted apparently by a sheltered and sunny recess in which scarlet geraniums and bignonias were in full flower, the moth darted downwards, and, after a little hovering, settled suddenly on the bare ground underneath a geranium-plant. I then saw that it was a very handsome species, with an elaborate pattern of light and dark chocolate browns. But the margins of the upper or anterior wings, which were deeply waved in outline, had a lustrous yellow color, like a brilliant gleam of light. In this position the moth was a conspicuous object. After resting for a few seconds, apparently enjoying the sun, it seemed to notice some movement which gave it alarm. It then turned slightly round, gave a violent jerk to its wings, and instantly became invisible. If it had subsided into a hole in the ground, it could not have more completely disappeared. As, however, my eyes were fixed upon the spot, I soon observed that all the interstices among the little clods around were full of withered and crumpled leaves of a deep blackish brown. I then further noticed that the spot where the moth had sat was apparently occupied by one of these, and it then flashed upon me in a moment that I had before me one of the great wonders and mysteries of Nature.—ARGYLL *Unity of Nature*, ch. 3, p. 52. (Burt.)

2250. MOTH TRUSTING ITS INVISIBILITY—*Protective Mimicry a Source of Confidence.*—And now I tried an experiment to test another feature in the wonderful instincts which are involved in all these operations. That feature is the implicit confidence in its success which is innate in all creatures furnished with any apparatus of concealment. I advanced in the full sunlight close up to the moth—so close that I could see the prominent "beaded eyes," with the watchful look, and the roughened outlines of the thorax, which served to complete the illusion. So perfect was the deception that I really could not feel absolutely confident that the black spot I was examining was what I believed it to be. Only one little circumstance reassured me. There was a small hole in the outer covering through which a mere point of the inner brilliant margin could be seen shining like a star. Certain now as to the identity of the moth, I advanced still nearer, and finally I found that it was not till the point of a stick was used to touch and shake the earth on which it lay that the creature could believe that it was detected and in danger. Then in an instant, by movements so rapid as to escape the power of vision, the dried and crumpled leaf became a living moth, with energies of flight defying all attempts at capture. [See MIMICRY, PROTECTIVE.]—ARGYLL *Unity of Nature*, ch. 3, p. 52. (Burt.)

2251. MOTHERHOOD, THE EVOLUTION OF—*Elementary Animals Orphans.*—Crossing into the animal kingdom we observe the same motherless beginning [as among the plants]. All elementary animals are orphans; they know neither home nor care; the earth is their only mother or the inhospitable sea; they waken to isolation, to apathy, to the attentions only of those who seek their doom. But as we draw nearer the apex of the animal kingdom, the spectacle of a protective maternity looms into view. At what precise point it begins it is difficult to say. But that it does not begin at once—that there is a long and gradual evolution of maternity—is clear.—DRUMMOND *Ascent of Man*, ch. 8, p. 269. (J. P., 1900.)

2252. MOTHERHOOD THE MOST STUPENDOUS TASK OF EVOLUTION—The evolution of a mother, in spite of its half-humorous, half-sacrilegious sound, is a serious study in biology. Even on its physical side this was the most stupendous task evolution ever undertook. It began when the first bud burst from the first plant-cell, and was only completed when the last and most elaborately wrought pinnacle of the temple of Nature crowned the animal creation.—DRUMMOND *Ascent of Man*, ch. 8, p. 267. (J. P., 1900.)

2253. MOTHERHOOD, TRAINING FOR—*Care of Dolls an Inadequate Preparation.*—You present a little girl in her cradle with a doll, and let her play with it until she grows older. Then you add a doll's house and furnish it with every appurtenance you can find. Why? Because you want to prepare the child in her play for the activities of her future calling as a woman, because you desire to awaken the sensibilities of womanhood and direct them to the usages of the nursery. Very good! But after that there comes a great vacuum. The doll is relegated to a corner. The entire world appears to the maiden in disguise, veiled. Not until she faces her own child is the young mother placed before the real object. Do you not perceive that we have here a great error, the greatest that society makes? Do you not see that it is a sin to entrust a living child to a mother whose training for the earnest duty she now faces was received in a doll's house? And that, too, to a mother in such complicated circumstances as those of the society of our day, with all of its distractions, its quixotic fashions, its dislocated and superstitious traditions?—VIRCHOW *(a Lecture)*. (Translated for *Scientific Side-Lights.)*

2254. MOTION, APPARENT, OF THE SUN AMONG THE STARS—If we observe, night after night, the exact hour and minute at which a star passes any point by its

diurnal revolution, we shall find that passage to occur some four minutes earlier every evening than it did the evening before. The starry sphere therefore revolves, not in 24 hours, but in 23 hours 56 minutes. In consequence, if we note its position at the same hour night after night, we shall find it to be farther and farther to the west. Let us take, for example, the brightest star in the constellation Leo, . . . and commonly known as Regulus. If we watch it on the 22d of March, we shall find that it passes the meridian at ten o'clock in the evening. On April 22d it passes at eight o'clock, and at ten it is two hours west of the meridian. On the same day of May it passes at six, before sunset, so that it cannot be seen on the meridian at all. When it first becomes visible in the evening twilight, it will be an hour or more west of the meridian. In June it will be three hours west, and by the end of July it will set during twilight, and will soon be entirely lost in the rays of the sun. This shows that during the months in question the sun has been approaching the star from the west, and in August has got so near it that it is no longer visible. Carrying forward our computation, we find that on August 21st the star crosses the meridian at noon, and therefore at nearly the same time with the sun. In September it crosses at ten in the morning, while the sun is on the eastern side. The sun has therefore passed from the west to the east of the star, and the latter can be seen rising in the morning twilight before the sun. It constantly rises earlier and earlier, and therefore farther from the sun, until February, when it rises at sunset and sets at sunrise, and is therefore directly opposite the sun. In March the star would cross the meridian at ten o'clock once more, showing that in the course of a year the sun and star had resumed their first position. But, while the sun has risen and set 365 times, the star has risen and set 366 times, the sun having lost an entire revolution by the slow backward motion we have described. . . . The path which the sun describes among the stars in his annual revolution is called the ecliptic. . . . A belt of the heavens, extending a few degrees on each side of the ecliptic, is called the zodiac.—NEWCOMB *Popular Astronomy*, ch. 1, p. 14. (H., 1899.)

2255. MOTION AS ESSENTIAL IN THE SIDEREAL WORLD AS IN THE ORGANIC—If, . . . , we imagine the acuteness of our senses preternaturally heightened to the extreme limits of telescopic vision, bringing together events separated by wide intervals of time, the apparent repose which reigns in space will suddenly vanish. Countless stars will be seen moving in groups in various directions; nebulæ wandering, condensing, and dissolving like cosmical clouds; the Milky Way breaking up in parts and its veil rent asunder. In every point of the celestial vault we should recognize the dominion of progressive movement just as on the surface of the earth, where vegetation is constantly putting forth leaves and buds and unfolding into blossoms. The celebrated Spanish botanist, Cavanilles, first conceived the possibility of seeing grass grow by placing the horizontal micrometer wire of a telescope with a high magnifying power at one time on the point of a bamboo shoot, at another on the rapidly unfolding flowering stem of an American aloe, precisely as the astronomer places the cross of wires on a culminating star. Throughout the whole life of physical nature in the organic, as in the sidereal world, existence, preservation, production, and development, are alike associated with motion as their essential condition.—HUMBOLDT *Cosmos*, vol. i, p. 139. (Translated for *Scientific Side-Lights.*)

2256. MOTION, ATOMIC, NOT CONVERTIBLE INTO CONSCIOUSNESS—In his celebrated "Address to the Congress of German Naturforscher," delivered at Leipsic [in 1872] Du Bois-Reymond speaks thus: "What conceivable connection subsists between definite movements of definite atoms in my brain, on the one hand, and on the other hand such primordial, indefinable, undeniable facts as these: I feel pain or pleasure; I experience a sweet taste, or smell a rose, or hear an organ, or see something red. It is absolutely and forever inconceivable that a number of carbon, hydrogen, nitrogen, and oxygen atoms should be otherwise than indifferent as to their own position and motion, past, present, or future. It is utterly inconceivable how consciousness should result from their joint action."—TYNDALL *Fragments of Science*, vol. ii, ch. 11, p. 226. (A., 1900.)

2257. MOTION, CEASELESS, OF LUMINIFEROUS ETHER—We on the earth's surface live night and day in the midst of ethereal commotion. The medium is never still. The cloud canopy above us may be thick enough to shut out the light of the stars, but this canopy is itself a warm body, which radiates its thermal motion through the ether. The earth also is warm, and sends its heat-pulses incessantly forth. It is the waste of its molecular motion in space that chills the earth upon a clear night; it is the return of thermal motion from the clouds which prevents the earth's temperature on a cloudy night from falling so low. To the conception of space being filled we must, therefore, add the conception of its being in a state of incessant tremor.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 8. (A., 1897.)

2258. MOTION CONVERTED INTO HEAT—*Iron Made Hot by Hammering.*—Robert Boyle appears to have seen as clearly as we do to-day that when heat is generated by mechanical means, new heat is called into existence. In describing one of his experi-

ments he uses the following remarkable language: "It will be convenient to begin with an instance or two of the production of heat, wherein there appears not to intervene anything on the part of the agent or patient but local motion and the natural effects of it. When, for example, a smith does hastily hammer a nail or such like piece of iron the hammered metal will grow exceedingly hot; and yet there appears not anything to make it so, save the forcible motion of the hammer, which impresses a vehement and variously determined agitation of the small parts of the iron, which, being a cold body before, by that superinduced commotion of its small parts, becomes in divers senses hot; first, in a more lax acceptation of the word in reference to some other bodies, in respect of whom it was cold before, and then sensibly hot: because this newly gained agitation surpasses that of the parts of our fingers.—TYNDALL *Heat a Mode of Motion*, lect. 1, p. 34. (A., 1900.)

2259. MOTION CREATING HEAT—*Fire Kindled by Friction.*—Taking an elastic stick about eighteen inches long, he [the Guacho on the pampas] presses one end on his breast and the other (pointed) end into a hole in a piece of wood, and then rapidly turns the curved part, like a carpenter's center-bit.—DARWIN *Naturalist's Voyage around the World*, ch. 18, p. 409. (A., 1898.)

2260. MOTION ESSENTIAL TO LIFE—*Air and Water Made Habitable by Movement.*—It is not enough that we have the air in which we live and move, with all of its properties, as we have described: something more is needed which is absolutely essential both to animal and vegetable life, and this essential is motion. If the air remained perfectly still, with no lateral movement or upward and downward currents of any kind, we should have a perfectly constant condition of things, subjected only to such gradual changes as the advancing and receding seasons would produce owing to the change in the angle of the sun's rays. No cloud would ever form, no rain would ever fall, and no wind would ever blow. It is of the highest importance not only that the wind shall blow, but that comparatively sudden changes of temperature take place in the atmosphere, in order that vegetation as well as animal life may exist upon the surface of the globe. The only place where animal life could exist would be in the great bodies of water, and it is even doubtful if water could remain habitable unless there were means provided for constant circulation—motion.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 6, p. 45. (F. H. & H., 1900.)

2261. MOTION, HEAT LONG KNOWN AS—*Locke Foreshadows Molecular Theory.*—In his "Essay on the Human Understanding" Locke frequently refers to heat as being a kind of motion. But the very remarkable utterance which of late years has been most widely circulated is the following: "Heat," says Locke, "is a very brisk agitation of the insensible parts of the object, which produces in us that sensation from whence we denominate the object hot; so what in our sensation is heat, in the object is nothing but motion. This appears by the way heat is produced; for we see that the rubbing of a brass nail upon a board will make it very hot, and the axletrees of carts and coaches are often hot, and sometimes to a degree that it sets them on fire, by the rubbing of the naves of the wheels upon them. On the other side, the utmost degree of cold is the cessation of that motion of the insensible particles, which to our touch is heat."—LOCKE *Works*, vol. iv, p. 597, ed. of 1768, quoted by TYNDALL in *Heat a Mode of Motion*, lect. 2, p. 37. (A., 1900.)

2262. MOTION MAGNIFIED EQUALS TIME EXTENDED—*The Telescope Gives the Astronomer a Record of Ten Thousand Years.*—The magnifying power of the telescope in reality acts to magnify any effects of star motion. So that if a magnifying power of 100 is used, the astronomer could detect in one year any motion which, to the naked eye, would only be discernible in one hundred years.

Very few motions are discernible to ordinary vision (aided, of course, by an instrumental index devised to determine a star's place) in so short a time as one hundred years. But notice that in twenty or thirty years a telescopist, using the very moderate power named, would be able to detect a motion which ordinary vision would be able to recognize [only] after the lapse of two thousand or three thousand years. And our astronomers are not limited to twenty or thirty years. They can compare their observations with those made by such observers as Bradley and his contemporaries nearly a century and a half ago. This amounts, with moderate telescopic power, to the observation of effects equivalent to those which would be presented to the naked eye in the course of more than ten thousand years.—PROCTOR *Expanse of Heaven*, p. 281. (L. G. & Co., 1897.)

2263. MOTION NOT TO BE TRANSMUTED INTO SENSATION—*Thought Cannot Be Expressed in Terms of Chemistry.*—We can prove that bile arises in the liver by chemical processes which we are able, in part at least, to follow out in detail. We can show, too, that movement is produced in muscles by definite processes, which are again the immediate result of chemical transformation. But cerebral processes give us no shadow of indication as to how our mental life comes into being. For the two series of phenomena are not comparable. We can conceive how one motion may be transformed into another, perhaps also how

one sensation or feeling is transformed into a second. But no system of cosmic mechanics can make plain to us how a motion can pass over into a sensation or feeling.—WUNDT *Psychology,* lect. 1, p. 6. (Son. & Co., 1896.)

2264. MOTION OF STARS AND WORLDS HARMONIOUS—*A Shower of Stars—Pettiness of Merely Personal and Selfish Life.*—Thus perpetual motion bears the world along! The sun moves through space; the earth moves round him, letting herself be carried along in his flight; the moon moves, circulating round us, while we gravitate round the radiant hearth which precipitates itself into the eternal void. Like a shower of stars the worlds whirl, borne along by the winds of heaven, and are carried down through immensity; suns, earths, satellites, comets, shooting stars, humanities, cradles, graves, atoms of the infinite, seconds of eternity, perpetually transform beings and things; all move on, all wing their flight under the breath divine—while trade goes on, or the investor counts his gold and piles it up, believing that he holds the entire universe in his casket. O folly of terrestrial manikins! folly of busy merchants, folly of the miser, folly of the suitor, folly of the pilgrim to Mecca or to Lourdes, folly of the blind! When shall the inhabitant of the earth open his eyes to see where he is, to live the life of the mind, and to base his happiness on intellectual contemplations? When shall he throw off the old man, the animal cover, to free himself from the fetters of the flesh and soar in the heights of knowledge?—FLAMMARION *Popular Astronomy,* bk. ii, ch. 3, p. 109. (A.)

2265. MOTION OF STARS DETERMINED—*Spectroscopic Evidence of Approach or Recession.*—If the star is approaching or receding, the motion is reflected in the spectrum in a singular way. Let us suppose that it approaches. The lengths of the waves, which give rise to the diversity of colors, diminish, and the refrangibility of each color increases. If, then, we observe with a spectroscope two luminous sources, the one fixed (the electric tube), the other moving (the star), both giving, for example, the line ("D") so characteristic of sodium, we see in the two superposed spectra the rays of this metal, which will not coincide. The line D shown by the spectrum of the star will deviate from the line D shown by the tube, and the displacement will be towards the violet end if the star is approaching the earth, and towards the red end if it is receding. The difference will serve not only to ascertain whether the star is approaching or receding, but even to determine the velocity.—FLAMMARION *Popular Astronomy,* bk. vi, ch. 9, p. 648. (A.)

2266 MOTION PRODUCED BY HEAT—*Reconverted into Heat—Steam the Medium of Change.*—Those who have walked through the workshops of Woolwich, or through any of our great factories where machinery is extensively employed, will have been sufficiently impressed with the aid which the mighty power of heat renders to man. Let it be remembered that every wheel which revolves, every chisel, and plane, and punch, which passes through solid iron as if it were so much cheese, derives its moving energy from the clashing atoms in the furnace. The motion of these atoms is communicated to the boiler, thence to the water, whose molecules are shaken asunder, flying from each other with a repellent energy commensurate with the heat communicated. The steam is simply the apparatus, through the intermediation of which the atomic motion is converted into mechanical motion. And the motion thus generated always, in the long run, reproduces its parent. Look at the planing-tools and boring-instruments—streams of water gush over them to keep them cool. Take up the curled iron shavings which the planing-tool has pared off; you cannot hold them in your hand, they are so hot. Here the moving force is restored to its first form; the energy of the machine has been consumed in reproducing the power from which that energy was derived.—TYNDALL *Heat a Mode of Motion,* lect. 6, p. 165. (A., 1900.)

2267. MOTION TRANSFORMED INTO HEAT—*Heat Is Molecular Motion—Constancy of Force.*—In firing a ball against a target the projectile, after collision, is often found hot. Mr. Fairbairn informs me that in the experiments at Shoeburyness it is a common thing to see a flash, even in broad daylight, when the ball strikes the target. And if our lead weight be examined after it has fallen from a height it is also found heated. . . . When a violin bow is drawn across a string, the sound produced is due to motion imparted to the air, and to produce that motion muscular force has been expended. We may here correctly say that the mechanical force of the arm is converted into music. In a similar way we say that the arrested motion of our descending weight, or of the cannon-ball, is converted into heat. The mode of motion changes, but motion still continues; the motion of the mass is converted into a motion of the atoms of the mass; and these small motions, communicated to the nerves, produce the sensation we call heat.—TYNDALL *Fragments of Science,* vol. i, ch. 16, p. 371. (A., 1897.)

2268. MOTION, VIBRATION, AND HARMONY PERVADE ALL NATURE—*Correspondence of Music and Color.*—A universal motion bears along the stars, atoms of the infinite. The moon gravitates round the earth, the earth gravitates round the sun, the sun carries along all its planets and their satellites towards the constellation Hercules; and these motions are executed according to determined laws, like the hand of a watch which turns round its center, and like the circular undulations which are de-

veloped on the surface of still water when a point has been struck. This is a universal harmony which the physical ear cannot hear, as Pythagoras supposed, but which the intellectual ear can understand. And is it not music itself which vaguely lulls us on its seraphic wings, and so easily transports our minds into those ethereal regions of the ideal where we forget the fetters of matter? Do not the sonorous modulations of the organ, the sweet quiverings of the bow on the violin, the nervous languors of the cithara, or the still more captivating charm of the human voice, unite the raptures of life with the warm colors of harmony? What is it except an undulatory motion of the air contrived to reach the mind in the depths of the brain and to impress it with emotions of a special order? When the martial tones of the spirited "Marseillaise" are borne in the heat of the conflict to the excited battalions, or when, under the Gothic vault, the sad "Stabat" pours out its mournful notes, it is the vibration which affects us by speaking a mysterious language. Now, all in Nature is motion, vibration, and harmony. The flowers of the garden sing, and the effect which they produce depends on the number and agreement of their vibrations relatively to those which emanate from surrounding Nature. In violet light the atoms of the ether oscillate with the unheard-of rapidity of 740 billions of vibrations per second; red light, slower, is produced by undulations vibrating still at the rate of 380 billions per second. The violet color is, in the case of light, what the highest notes are in the case of sound, and the red color represents the lowest tones. As we see an object floating in the water obeying with docility the waves which come from different sides, so the atom of the ether undulates under the influence of light and heat, the atom of air undulates under the influence of sound, and the planet and satellite circulate under the influence of gravitation.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 1, p. 221. (A.)

2269. MOTION WITHIN THE WALLS OF PLANTS—*Varied and Intense Activity.*—Without entering on the difficult question of spontaneous motion, or, in other words, on the difference between vegetable and animal life, we would remark that if Nature had endowed us with microscopic powers of vision, and the integuments of plants had been rendered perfectly transparent to our eyes, the vegetable world would present a very different aspect from the apparent immobility and repose in which it is now manifested to our senses. The interior portion of the cellular structure of their organs is incessantly animated by the most varied currents, . . . rotating, ascending and descending, ramifying, and ever changing their direction. . . . If to these manifold currents and gyratory movements we add the phenomena of endosmosis, nutrition, and growth, we shall have some idea of those forces which are ever active amid the apparent repose of vegetable life.—HUMBOLDT *Cosmos*, vol. i, p. 341. (H., 1897.)

2270. MOTIVE AND VOLITION NOT MECHANICALLY CONNECTED—*Character Determines Decision.*—The uncertainty of the connection of motive and volition is due, and due only, to the existence of the personal factor. In consequence of this, all motives are seen to be insufficient for the complete explanation of a voluntary action; they can never be constraining causes, but remain as partial determinants. And the motives of volition are insufficient for its explanation, simply because the nature of the personal factor itself and the manner of its cooperation with external factors are wholly unknown. At the same time the fact that an ineffectual motive leaves no trace upon the completed volition points towards the inference that external motive and internal factor do not cooperate as does a plurality of causes in Nature, but that personality is the only immediate cause of action, *i. e.*, that the only direct effect of a motive is exerted upon the personality. Properly speaking, therefore, we may not talk of a "personal factor," since that expression implies the simultaneous cooperation of other factors. Rather, since all the immediate causes of voluntary action proceed from personality, we must look for the origin of volition in the inmost nature of personality—in character.—WUNDT *Human and Animal Psychology*, lect. 29, p. 433. (Son. & Co., 1896.)

2271. MOUND-BUILDERS' STRUCTURES—*Artistic Earthworks—The "Animal Mounds."*—Not the least remarkable of the American antiquities are the so-called "animal mounds," which are principally, tho not exclusively, found in Wisconsin. In this district "thousands of examples occur of gigantic basso-relievos of men, beasts, birds, and reptiles, all wrought with persevering labor on the surface of the soil," while enclosures and works of defense are almost entirely wanting. — AVEBURY *Prehistoric Times*, ch. 8, p. 253. (A., 1900.)

2272. ——— ——— *Silent Evidence of Dense Agricultural Population — A Race without a Record.*—No proof of a knowledge of letters, no trace of a burnt brick, have yet been discovered; and so far as we may judge from their arms, ornaments, and pottery, the mound-builders closely resembled the more advanced of the recent Indian tribes, and the earthworks agree in form with, if they differ in magnitude from, those still, or until lately, in use. Yet this very magnitude is sufficient to show that, at some early period, the great river valleys of the United States must have been more densely populated than they were when first discovered by Europeans. . . . The Newark constructions; the mound near Florence in Alabama, which is forty-five feet in height by four hundred and forty feet in circumfer-

ence at the base, with a level area at the summit of one hundred and fifty feet in circumference; . . . these works, and many others which might have been quoted, indicate a population both large and stationary; for which hunting cannot have supplied enough food, as it has been estimated that in a forest country each hunter requires an area of not less than 50,000 acres for his support; and which must, therefore, have derived its support, in a great measure, from agriculture.—AVEBURY *Prehistoric Times*, ch. 8, p. 259. (A., 1900.)

2273. MOUNTAIN ENGULFED IN EARTH—*Earthquake in Java—Truncation of a Lofty Cone.*—In the year 1772, Papandayang, formerly one of the loftiest volcanoes in the island of Java, was in eruption. Before all the inhabitants on the declivities of the mountain could save themselves by flight, the ground began to give way, and a great part of the volcano fell in and disappeared. It is estimated that an extent of ground of the mountain itself and its immediate environs, fifteen miles long and full six broad, was by this commotion swallowed up in the bowels of the earth. Forty villages were destroyed, some being engulfed, and some covered by the substances thrown out on this occasion, and 2,957 of the inhabitants perished. . . . This catastrophe appears to have resembled, tho on a grander scale, that of the ancient Vesuvius in the year 79.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 493. (A., 1854.)

2274. MOUNTAIN SLOWLY SINKING—*Wider Prospect from Neighboring Heights—Earth's Crust Changing Now.*—Two examples of rapid earth-movement are taken from Professor Rossi's "Meteorologia Endogena." Professor D. Seghetti, writing to Professor Rossi, says that a few lusters ago (one luster = twenty years) Mount S. Giovanni hid the towns Jenne and Subiaco from each other. From Subiaco the church at Jenne is now visible, which a few years ago was invisible. The people at Jenne also can see more than formerly. The supposition is that the side of Mount S. Giovanni is lowered. This fact corresponds to a fact stated by Professor Carina, who says that forty or fifty years ago from Granaiola you could not see either the church of S. Maria Assunta di Citrone or the church of S. Pietro di Corsena. Now you can see both.—MILNE *Earthquakes*, ch. 21, p. 351. [A. 1899.]

2275. MOUNTAIN-BUILDING A LONG AND COMPLICATED PROCESS—*Extends through Ages (Ps. xc, 2).*—Mountain chains may be regarded as cicatrized wounds in the earth's solid crust. A line of weakness first betrays itself at a certain part of the earth's surface by fissures, from which volcanic outbursts take place; and thus the position of the future mountain chain is determined. Next, subsidence during many millions of years permits of the accumulation of the raw materials out of which the mountain range is to be formed; subsequent earth-movements cause these raw materials to be elaborated into the hardest and most crystalline rock-masses, and place them in elevated and favorable positions; and lastly, denudation sculptures from these hardened rock-masses all the varied mountain forms. Thus the work of mountain-making is not, as was formerly supposed by geologists, the result of a simple upheaving force, but is the outcome of a long and complicated series of operations.—JUDD *Volcanoes*, ch. 10, p. 300. (A., 1899.)

2276. MOUNTAINS AS A DEFENSE AGAINST EARTHQUAKES—*Shocks Limited by Mountain Ranges.*—All earthquake disturbances have probably a tendency to radiate in a uniform manner from their source, and are only prevented from doing so by meeting with heavy mountainous districts, which by their mass and structure absorb the energy communicated to them. Much energy is also lost by emergence on the open flanks of a range of mountains. Rather than say that high mountains often bound the extension of an earthquake, or that earthquakes appear to run along the flanks of such mountains, we might say that earthquakes have boundaries parallel to the strike of the rocks in a given district, that such a direction is the one in which the propagation is the easier.—MILNE *Earthquakes*, ch. 12, p. 230. (A., 1899.)

2277. MOUNTAINS OF ETERNAL LIGHT—At the lunar poles (where, moreover, we see neither snow nor ice) there are mountains so strangely situated that their summits know no night; the sun never sets on them. They may be called the mountains of eternal light.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 4, p. 123. (A.)

2278. MOUNTAINS PILED BY VOLCANIC ERUPTIONS—*Caverns Hollowed beneath the Earth—Earthquakes Due to Collapse of Caverns.*—By the ejection of ashes and lava from volcanic vents an extensive evisceration of the neighboring ground might be expected. When we look at a volcano like Fujiyama, nearly 13,000 feet in height, and at least fifty miles in circumference, and remember that the mass of cinders and slag of which it is composed came from beneath the area on which it rests, the point to be wondered at is that earthquakes, consequent on the collapse of subterranean hollows, are not more frequent than they are. At the time of a single eruption of a volcano the quantity of lava ejected amounts to many thousand millions of cubic feet. In 1783 the quantity of lava ejected from Skaptar Jokul, in Iceland, was estimated as surpassing "in magnitude the bulk of Mont Blanc." . . . Beneath a volcano it is probable that viscous material immediately takes the place of that which is ejected, and that hollows are not formed as in the case of chemical degradation. If

a cavern becomes too large it eventually collapses.—MILNE *Earthquakes,* ch. 17, p. 285. (A., 1899.)

2279. MOUNTAINS SHATTERED—*Mountainsides Denuded—Rivers Checked—Fish Taken on Land.*—The Blue, and other of the highest mountains [in Jamaica, in the earthquake of 1692], are declared to have been strangely torn and rent. They appeared shattered and half naked, no longer affording a fine green prospect, as before, but stripped of their woods and natural verdure. The rivers on these mountains first ceased to flow for about twenty-four hours, and then brought down into the sea, at Port Royal and other places, several hundred thousand tons of timber, which looked like floating islands on the ocean. The trees were in general barked, most of their branches having been torn off in the descent. It is particularly remarked in this as in the narratives of so many earthquakes, that fish were taken in great numbers on the coast during the shocks. The correspondents of Sir Hans Sloane, who collected with care the accounts of eye-witnesses of the catastrophe, refer constantly to subsidences, and some supposed the whole of Jamaica to have sunk down.—LYELL *Principles of Geology,* bk. ii, ch. 29, p. 505. (A., 1854.)

2280. MOUNTAINS SNOW-CLAD—*Meaning of "Perpetual Snow"—Perpetual Change and Renewal.*—The term "perpetual snow" should not lead any one to suppose that there is any elevation at which snow, after falling, remains absolutely unchanged. All the snow that falls on the mountains, however high, is destined to disappear in course of time. It may gradually be forced down by the weight of new accumulations to levels at which it melts and runs away as water; it may be blown down to lower and warmer levels, and in this way great quantities of snow are removed by every high wind on snow-clad mountains: it may be melted by the heat of the sun far above the snow-line, or it may evaporate or disappear insensibly in the form of invisible vapor. . . .

It is not, then, because the snow that falls on the tops of mountains remains always the same, that there is a limit of perpetual snow on the highest mountains, even in the tropics. But this limit is that at which snow never altogether disappears before fresh snow has fallen to take its place. It is for that reason that it is not temperature alone that determines the height of the snow-line.—CHISHOLM *Nature-Studies,* p. 33. (Hum., 1888.)

2281. MOVEMENT, MOLECULAR, CONTAINS NO SUGGESTION OF CONSCIOUSNESS—The consensus of scientific opinion here is extraordinary. "I know nothing," says Huxley, in the name of biology, "and never hope to know anything, of the steps by which the passage from molecular movement to states of consciousness is effected." "The two things," emphasizes the physicist, "are on two utterly different platforms: the physical facts go along by themselves, and the mental facts go along by themselves." "It is all through and forever inconceivable," protests the German physiologist [Du Bois-Reymond], "that a number of atoms of carbon, hydrogen, nitrogen, oxygen, and so on, shall be other than indifferent as to how they are disposed and how they move, how they were disposed and how they moved, how they will be disposed and how they will be moved. It is utterly inconceivable how consciousness shall arise from their joint action." [Compare MOTION, ATOMIC, 2256.]—DRUMMOND *Ascent of Man,* ch. 4, p. 124. (J. P., 1900.)

2282. MOVEMENT OF A DAY CHANGES FACE OF THE EARTH—*Lava-stream Forming Lake—Plastic Current Hardens to Rock.*—A lava-stream may cross a valley so as to obstruct its drainage and cause a lake to form above it, in much the same way as glaciers dam lateral valleys. A large lake was formed in this manner, probably in Pleistocene times, on the Yukon River, Alaska, where it is joined by Pelly River. A series of lava-flows there filled the river valley from side to side to a depth of several hundred feet, and formed a dam which retained the waters of the Yukon, and gave origin to a broad water body known as Lake Yukon. The obstruction has since been cut through along the southern margin of the old channel, leaving a series of basaltic precipices on the right bank of the river.—RUSSELL *Lakes of North America,* ch. 1, p. 17. (G. & Co., 1895.)

2283. MOVEMENT OF ENTIRE SOLAR SYSTEM THROUGH SPACE—*Swiftness of the Motion—We Are Part of a Universal System.*—Sir W. Herschel first, and afterwards several other astronomers, have, by the careful study of the stars' movements, ascertained, with what amounts practically to absolute certainty, that our sun, with his whole family of planets, is moving towards the part of the heavens occupied by the constellation Hercules. Every investigation of the evidence has led to the same general result in this respect. . . . It has been said that the sun is traveling at the rate of three or four miles in every second of time. But when one examines the evidence one finds that this conclusion depends on assumptions as to the average real magnitude of the stars of various orders of apparent brightness. I was long since led to conclude that such assumptions were unsafe, and also to infer from certain evidence which I had collected that our sun moves much more swiftly than had been supposed.—PROCTOR *Expanse of Heaven,* p. 289. (L. G. & Co., 1897.)

2284. MOVEMENT OF MUTILATED ANIMAL—*Reflex Action Becomes Purely Mechanical.*—Surely the reasoning is bad which argues that because a given movement goes

on after the animal has been mutilated, this movement must therefore continue to possess all the same elements of character which accompanied it when the animal was complete. And not only is the reasoning bad, but as a matter of fact the conclusion has been proved to be erroneous. Farther investigations have shown that when the cerebral hemispheres have been removed the "reflex action" in a frog's leg acquires a new character. It becomes a mere result of physical causation, and is consequently as certain and inevitable as the action of a coiled spring. Accordingly, it can be predicted and foreseen with certainty. In short, the mental element has been eliminated along with that part of the machinery which is the organ of consciousness and will. But when that part of the machinery remains untouched, then "reflex action" loses its character of necessity as the result of mere mechanical causation. It cannot be predicted with certainty, because altho the "stimulus" may be the same, and the animal impulse may be the same, there is a controlling apparatus to which has been given the free and incalculable power of resisting both stimulus and impulse. Both parts of the apparatus are equally machinery. But the one has a mental function, and the other has a function purely physical.—ARGYLL *Unity of Nature*, ch. 3, p. 65. (Burt.)

2285. MOVEMENT, SUSTAINED, WITH SLIGHT EXERTION—*The Condor's Flight.*—When the condors are wheeling in a flock round and round any spot, their flight is beautiful. Except when rising from the ground I do not recollect ever having seen one of these birds flap its wings. Near Lima I watched several for nearly half an hour without once taking off my eyes: they moved in large curves, sweeping in circles, descending and ascending without giving a single flap. As they glided close over my head I intently watched from an oblique position the outlines of the separate and great terminal feathers of each wing: and these separate feathers, if there had been the least vibratory movement, would have appeared as if blended together; but they were seen distinct against the blue sky. The head and neck were moved frequently and apparently with force; and the extended wings seemed to form the fulcrum on which the movements of the neck, body, and tail acted. If the bird wished to descend, the wings were for a moment collapsed; and when again expanded with an altered inclination the momentum gained by the rapid descent seemed to urge the bird upwards with the even and steady movement of a paper kite. In the case of any bird soaring, its motion must be sufficiently rapid so that the action of the inclined surface of its body on the atmosphere may counterbalance its gravity. The force to keep up the momentum of a body moving in a horizontal plane in the air (in which there is so little friction) cannot be great, and this force is all that is wanted. The movement of the neck and body of the condor, we must suppose, is sufficient for this. However this may be, it is truly wonderful and beautiful to see so great a bird, hour after hour, without any apparent exertion, wheeling and gliding over mountain and river.—DARWIN *Naturalist's Voyage around the World*, ch. 9, p. 186. (A., 1898.)

2286. MOVEMENT UNIVERSAL IN PLANTS—*Generally Spiral in Character—Circumnutation.*—The most widely prevalent movement is essentially of the same nature as that of the stem of a climbing plant, which bends successively to all points of the compass, so that the tip revolves. This movement has been called by Sachs "revolving nutation"; but we have found it much more convenient to use the terms *circumnutation* and *circumnutate.* As we shall have to say much about this movement, it will be useful here briefly to describe its nature. If we observe a circumnutating stem, which happens at the time to be bent, we will say, towards the north, it will be found gradually to bend more and more easterly, until it faces the east; and so onwards to the south, then to the west, and back again to the north. If the movement had been quite regular the apex would have described a circle, or rather, as the stem is always growing upwards, a circular spiral. But it generally describes irregular elliptical or oval figures; for the apex, after pointing in any one direction, commonly moves back to the opposite side, not, however, returning along the same line. Afterwards other irregular ellipses or ovals are successively described, with their longer axes directed to different points of the compass. Whilst describing such figures the apex often travels in a zigzag line, or makes small subordinate loops or triangles. In the case of leaves the ellipses are generally narrow.—DARWIN *Power of Movement in Plants*, ch. 1, p. 1. (A., 1900.)

2287. ———— ———— *New Results Reached by Ceaseless Striving—Effects of Circumnutation.*—Apparently every growing part of every plant is continually circumnutating [see 2286], tho often on a small scale. Even the stems of seedlings before they have broken through the ground, as well as their buried radicles, circumnutate, as far as the pressure of the surrounding earth permits. In this universally present movement we have the basis or groundwork for the acquirement, according to the requirements of the plant, of the most diversified movements. Thus, the great sweeps made by the stems of twining plants, and by the tendrils of other climbers, result from a mere increase in the amplitude of the ordinary movement of circumnutation. The position which young leaves and other organs ultimately assume is acquired by the

circumnutating movement being increased in some one direction. The leaves of various plants are said to sleep at night, and it will be seen that their blades then assume a vertical position through modified circumnutation, in order to protect their upper surfaces from being chilled through radiation. The movements of various organs to the light, which are so general throughout the vegetable kingdom, and occasionally from the light, or transversely with respect to it, are all modified forms of circumnutation, as again are the equally prevalent movements of stems, etc., towards the zenith, and of roots towards the center of the earth.—DARWIN *Power of Movement in Plants*, ch. 1, p. 3. (A., 1900.)

2288. MOVEMENTS, AUTOMATIC—*Education Makes Reflex Action Habitual and Easy—Superfluous Activity Eliminated.*—In our first attempts to write, to cipher, to play on an instrument, to speak, or in any other work of mechanical skill, the inward sense of labor and difficulty is corresponded to by the number of awkward and irrelevant gesticulations. On the other hand, in the last stage of consummated facility and routine, the consciousness is almost nothing; and the general quietude of the body demonstrates that the course of power has now become narrowed to the one channel necessary for the exact movements required. This is a sort of educated imitation of the primitive reflex movement adduced at the outset; the comparison is so striking as to suggest to physiologists the designation of secondary reflex or automatic for the habitual movements. A man at a signal-post, after long habit, is subjected to little or no nervous influence, except in the single thread of connection between a certain figure depicted on the eye and a certain movement of the hand; the collaterals of the primitive wave have died away, and the accompanying consciousness has fallen to a barely discernible trace.—BAIN *Mind and Body*, ch. 4, p. 14. (Hum., 1880.)

2289. ——— ——— *Mental Association Tends to Repeat Itself—Greek Verbs Learned by Hearing Recitation.*—A series of movements repeated in a certain order tend to unroll themselves with peculiar ease in that order forever afterward. Number one awakens number two, and that awakens number three, and so on, till the last is produced. A habit of this kind once become inveterate may go on automatically. And so it is with the objects with which our thinking is concerned. With some persons each note of a melody, heard but once, will accurately revive in its proper sequence. Small boys at school learn the inflections of many a Greek noun, adjective, or verb from the reiterated recitations of the upper classes falling on their ear as they sit at their desks. All this happens with no voluntary effort on their part, and with no thought of the spelling of the words.—JAMES *Psychology*, vol. i, ch. 14, p. 554. (H. H. & Co., 1899.)

2290. ——— ——— *Muscular Activities Repressed or Reenforced by Volition—Fatigue Requires Exertion of the Will.*—Each individual movement [in walking] suggests the succeeding one, and the repetition continues until, the attention having been recalled, the automatic impulse is superseded by the control of the will. Further, the direction of the movement is given by the sense of sight, which so guides the motions of our legs that we do not jostle our fellow-passengers or run up against lamp-posts; and the same sense directs also their general course along the line that habit has rendered most familiar, altho at the commencement of our walk we may have intended to take some other. Suppose our walk to be so prolonged, however, that the sense of fatigue comes on before we have reached its appointed conclusion. This calls off our attention from what is going on in the mind to the condition of the body; and in order to sustain the movements of locomotion a distinct exertion of the will comes to be requisite for each. With the increasing sense of fatigue an increased effort becomes necessary, and at last even the most determined volition may find itself unable to evoke a respondent movement from the exhausted muscles.—CARPENTER *Mental Physiology*, bk. i, ch. 1, § 16, p. 18. (A., 1900.)

2291. ——— ——— *Voluntary and Involuntary Activity Combined—Walking, Running, Writing, Etc., Done Chiefly by Reflex Action—Volition May Become a Hindrance.*—Reflex acts performed under the influence of the reflecting power of the spinal cord are essentially independent of the brain, and may be performed perfectly when the brain is separated from the cord. [It may be affirmed] that these include a much larger number of the natural and purposive movements of the lower animals than of the warm-blooded animals and man; and that over nearly all of them the mind may exercise, through the higher nerve-centers, some control, determining, directing, hindering, or modifying them, either by direct action, or by its power over associated muscles.

To these instances of spinal reflex action some add yet many more, including nearly all the acts which seem to be performed unconsciously, such as those of walking, running, writing, and the like, for these are really involuntary acts. It is true that at their first performances they are voluntary, that they require education for their perfection, and are at all times so constantly performed in obedience to a mandate of the will that it is difficult to believe in their essentially involuntary nature. But the will really has only a controlling power over their performance; it can hasten or stay them, but it has little or nothing to

do with the actual carrying out of the effect. And this is proved by the circumstance that these acts can be performed with complete mental abstraction; and, more than this, that the endeavor to carry them out entirely by the exercise of the will is not only not beneficial, but positively interferes with their harmonious and perfect performance. Any one may convince himself of this fact by trying to take each step as a voluntary act in walking down-stairs, or to form each letter or word in writing by a distinct exercise of the will.—BAKER *Handbook of Physiology,* vol. ii, ch. 18, p. 102. (W. W., 1885.)

2292. MOVEMENTS OF EARTH'S CRUST—*"Terra Firma" a Delusion.*—The folds and corrugations of the strata and the numerous dislocations by which rocks of all kinds are traversed clearly demonstrate that movements of the solid crust have taken place. Such crustal disturbances are probably in chief measure due to the fact that the earth is a cooling body. As the solid crust sinks down upon the cooling and contracting nucleus, it must occupy less superficial space. Hence its rocky framework becomes subjected to enormous tangential squeezing and compression, to which it yields by bending and folding, by fracture and displacement.—GEIKIE *Earth Sculpture,* ch. 1, p. 13. (G. P. P., 1898.)

2293. MOVEMENTS OF FLYING-FISH—*A True Flight—Fear Drives the Fish into Alien Element of Air.*—I have had frequent occasions to observe the flying-fishes attentively. I am confident not only that they change the direction of their flight, but that they raise or lower their line of movement repeatedly, without returning to the water. I avoid the word "falling" designedly, for all the acts of these fishes during their flight seem to me completely voluntary. They raise themselves from the surface of the water by rapidly repeated blows with the tail, and more than once have I seen them descend again to the surface of the water in order to repeat this movement; thus renewing the impulse and enabling themselves to continue for a longer time their passage through the air. Their changes of direction, either to the right and left or in rising and descending, are not due to the beating of the wings, that is to say, of the great pectoral fins, but simply to an inflection of the whole surface, in one or the other direction, by the contraction of the muscles controlling the action of the fin-rays, their pressure against the air determining the movement. The flying-fish is in fact a living shuttlecock, capable of directing its own course by the bending of its large fins. It probably maintains itself in the air until the necessity of breathing compels it to return to the water. The motive of its flight seems to me to be fear; for it is always in the immediate neighborhood and in front of the vessel that they are seen to rise; or perhaps at a distance when they are pursued by some large fish.—AGASSIZ *Journey in Brazil,* ch. 2, app., p. 522. (H. M. & Co., 1896.)

2294. MOVEMENTS OF MUSCLES ASSIGNED TO CENTERS IN THE BRAIN—Dr. R. W. Amidon in 1880 [succeeded in localizing] the heat produced [in the brain] by voluntary muscular contractions. Applying a number of delicate surface-thermometers simultaneously against the scalp, he found that when different muscles of the body were made to contract vigorously for ten minutes or more, different regions of the scalp rose in temperature, that the regions were well localized, and that the rise of temperature was often considerably over a Fahrenheit degree. As a result of his investigations he gives a diagram in which numbered regions represent the centers of highest temperature for the various special movements which were investigated. To a large extent they correspond to the centers for the same movements assigned by Ferrier and others on other grounds; only they cover more of the skull.—JAMES *Psychology,* vol. i, ch. 3, p. 100. (H. H. & Co., 1899.)

2295. MOVEMENTS WITH REFERENCE TO ENDS—*A Faculty of Plants as Well as of Animals—Venus's Fly-trap—Climbing Tendril.*—The faculty of making movements in reference to ends, affirmed of animals, was long denied to plants. . . . To show the breaking-down of the distinction, it would suffice to contrast the rooted fixity and vegetative growth of very many lower animals with the free locomotion of most microscopic aquatic plants and of the germs of those not microscopic. Is there not an independent movement, in response to an external impression, and in reference to an end, when the two sides of the trap of *Dionæa* [or Venus's fly-trap] suddenly enclose an alighted fly, cross their fringe of marginal bristles over the only avenue of escape, remain quiescent in this position long enough to give a small fly full opportunity to crawl out, soon open if this happens, but after due interval shut down firmly upon one of greater size which cannot get out, then pour out digestive juices, and in due time reabsorb the whole? So, . . . when a free revolving tendril avoids winding up itself uselessly around the stem it belongs to . . . by changing from the horizontal to the vertical position until it passes by it, and then rapidly resumes its horizontal sweep, to result in reaching a distant support—is it possible to think that these are not movements in reference to ends?—ASA GRAY *Natural Science and Religion,* lect. 1, p. 22. (S., 1891.)

2296. MULTIPLICATION BY DIVISION AMONG BACTERIA—Division, or fission, is the commonest method of reproduction [of bacteria]. It occurs transversely. A small indentation occurs in the capsule, which appears to make its way slowly through the whole body of the bacillus or micrococcus

until the two parts are separate, and each contained in its own capsule.—NEWMAN *Bacteria*, ch. 1, p. 16. (G. P. P., 1899.)

2297. MULTIPLICATION, INCONCEIVABLY RAPID, OF BACTERIA—Simple fission requires but a short period of time to be complete. Hence multiplication is very rapid, for within half an hour a new adult individual can be produced. It has been estimated that at this rate one bacillus will in twenty-four hours produce 17,000,000 similar individuals; or, expressed in another way, Cohn calculated that in three days, under favorable circumstances, this rate of increase would form a mass of living organisms weighing 7,300 tons, and numbering about 4,772 billions. Favorable conditions do not occur, fortunately, to allow of such increase, which, of course, can only be roughly estimated. But the above figures illustrate the enormous fertility of micro-organic life. When we remember that in some species it requires 10,000 or 15,000 fully grown bacilli placed end to end to stretch the length of an inch, we see also how exceedingly small are the individuals composing these unseen hosts.—NEWMAN *Bacteria*, ch. 1, p. 16. (G. P. P., 1899.)

2298. MULTIPLICATION OF PESTS—*Unintended Results of Commerce.*—Sometimes we unintentionally promote the multiplication of inimical species, as when we introduced the rat, which was not indigenous in the New World, into all parts of America. They have been conveyed over in ships, and now infest a great multitude of islands and parts of that continent. In like manner the Norway rat *(Mus decumanus)* has been imported into England, where it plunders our property in ships and houses. —LYELL *Geology*, ch. 39, p. 663. (A., 1854.)

2299. MULTITUDE OF BIRDS BY NIGHT IN UPPER AIR—*Telescope Reveals Them against the Moon.*—Some idea may be formed of the multitude of birds which throng the upper air on favorable nights, during their migration, by using a telescope. One having a two-inch object-glass will answer the purpose. It should be focused on the moon when the birds in passing are silhouetted against the glowing background. At the proper focal distance they appear with startling distinctness. In some cases each wing-beat can be detected, and with a large glass it is even possible to occasionally recognize the kind of bird. — CHAPMAN *Bird-Life*, ch. 4, p. 56. (A., 1900.)

2300. MUSEUM, ANCIENT, OF NATURAL CURIOSITIES — *Cooperation of Conqueror and Philosopher—Alexander Aids Aristotle—The Lykeum at Athens.*—In the spring of B. C. 334, Alexander of Macedon crossed the Hellespont and began the famous campaign which left him master of all the countries between the Danube and the Ganges. At about the same time Aristotle, who had been his preceptor, established a school at the Lykeum at Athens, and began to gather collections of plants, animals, and minerals, wherewith he illustrated his lectures, delivered while walking up and down the leafy paths which wound through the adjacent gardens. In this undertaking he found in his powerful disciple a most willing ally; for Alexander not only contributed a vast sum of money for the purchase of rare objects, but employed thousands of men to collect and transport to Athens all that was strange to the Greeks in the distant countries which had yielded to his arms.

To the gathering of this stupendous mass of material may be traced three results of the highest import: first, the acquisition of the multitudinous physical facts which fill the Aristotelian treatises on natural sciences; second, the foreshadowing of the inductive method of reasoning; third, the production by Theophrastus, the Lesbian, of a history of stones, probably based directly upon the study of Aristotle's collections.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 2, p. 38. (J. W., 1898.)

2301. MUSIC, NATURAL INSTRUMENTS OF—*The Wood-cricket of Brazil (the Tananá)—Contrivance as of Violin and Bow.*—A strange kind of wood-cricket is found in this neighborhood, the males of which produce a very loud and not unmusical noise by rubbing together the overlapping edges of their wing-cases. The notes are certainly the loudest and most extraordinary that I ever heard produced by an orthopterous insect. The natives call it the *Tananá*, in allusion to its music, which is a sharp, resonant stridulation resembling the syllables "ta-na-ná, ta-na-ná," succeeding each other with little intermission. It seems to be rare in the neighborhood. When the natives capture one they keep it in a wicker-work cage for the sake of hearing it sing. A friend of mine kept one six days. It was lively only for two or three, and then its loud note could be heard from one end of the village to the other. When it died he gave me the specimen, the only one I was able to procure. It is a member of the family *Locustidæ*, a group intermediate between the crickets *(Achetidæ)* and the grasshoppers *(Acridiidæ)*. The total length of the body is two inches and a quarter; when the wings are closed the insect has an inflated vesicular or bladder-like shape, owing to the great convexity of the thin but firm parchmenty wing-cases, and the color is wholly pale green. The instrument by which the tananá produces its music is curiously contrived out of the ordinary nervures of the wing-cases. In each wing-case the inner edge, near its origin, has a horny expansion or lobe: on one wing this lobe has sharp raised margins; on the other the strong nervure which traverses the lobe on the other side is crossed by a number of fine sharp furrows like those of a file. When

the insect rapidly moves its wings the file of the one lobe is scraped sharply across the horny margin of the other, thus producing the sounds, the parchmenty wing-cases and the hollow drumlike space which they enclose assisting to give resonance to the tones.—BATES *The Naturalist on the River Amazon*, ch. 6, p. 672. (Hum., 1880.)

2302. MUSIC OF PRIMITIVE WOMAN —*Domestic and Maternal Type Controls.*—It was with genuine pleasure that the author heard Mr. Cushing say that the women of Zuñi, tho they never play upon any of the musical instruments of the tribe, sing songs of their own, which are invariably associated with domestic and industrial pursuits. As they nurse their children they croon a lullaby, and more novel than that are the little melodies which they chant as they plant the corn or beans or melons to encourage their growth. The theory of the Zuñi woman seems to be that there is some mysterious connection between the voices or sounds of things and their increase. When she kneels by her stone bread-making trough she sings a song which has many little imitations of the mealing-stone. The theory in her mind is that the implement will do far better work under those circumstances. It is the same when she sings to her baby. Her boy she calls her little man, and speaks of all she hopes he may become, believing that these are necessary to his growth. This serious intent goes through all her music.—MASON *Woman's Share in Primitive Culture*, ch. 8, p. 176. (A., 1894.)

2303. MUSIC, PLAINTIVE—*Melancholy Appeals to the Common People.*—Even on joyous occasions the lower classes love melodies that are mournful, and their music in general tends to plaintive feelings and melancholy.—FLACH *Der Tanz bei den Griechen (a Lecture)*. (Translated for *Scientific Side-Lights.*)

2304. MYRIADS OF SUNS—*One Hundred Million Stars.*—We find for the total of stars down to the 14th magnitude inclusive the number, already difficult to imagine, of *forty-four millions.*

But these are not *all* the stars. Already even the powerful telescopes constructed in recent years have penetrated the depths of immensity so far as to discover stars of the 15th magnitude, and the stellar statistics have now risen to *one hundred millions!* Celestial photography penetrates further still, and the numbers become so enormous that we are overwhelmed by their weight without understanding them.

One hundred millions of stars! This gives 17,000 stars for each of those which we see with the naked eye—seventeen times more than we can count in both hemispheres. We shall shortly estimate the distances which separate them, and the incomparable space over which their empire extends.

One hundred millions of suns similar to ours, and surrounded by worlds counted by thousands of millions! These are, unquestionably, very amazing numbers, and it would not be surprising if they should not be at once realized in their prodigious magnitude by our brains, unaccustomed to such enormous figures. We may remark, however, in passing, that a number well understood tells more than the finest phrases.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 4, p. 587. (A.)

2305. MYSTERIES OF ARCHEOLOGY —*A Race Vanished without a Record.*—When, why, or by whom [the mounds of North America] were erected as yet we know not. The Indian tribes, tho they look upon them with reverence, have thrown no light upon their origin. Nor do the contents of the mounds themselves assist us in this inquiry. Several of them have been opened, and in making the streets of Milwaukee many of the mounds have been entirely removed; but the only result has been to show that they are not sepulchral, and that, excepting by accident, they contain no implements or ornaments. *

Under these circumstances speculation would be useless; we can but wait, and hope that time and perseverance may solve the problem, and explain the nature of these remarkable and mysterious monuments.—AVEBURY *Prehistoric Times*, ch. 8, p. 257. (A., 1900.)

2306. MYSTERY AMID THE MOUNTAINS—*Lake without Tributary or Outlet—Crater Lake—A Mountain Peak Obliterated.* —Crater Lake has been described by C. E. Dutton, and is considered by him as worthy of a high rank among the wonders of the world. It is situated in the Cascade Mountains, in northwestern Oregon, thirty miles north of Klamath Lake, at an elevation of 6,239 feet above the sea. It is nearly circular, without bays or promontories, . . . and is from five to six miles in diameter. The cliffs of dark basaltic rock encircling it rise precipitously to heights varying from 900 to 2,200 feet, and nowhere offer an easy means of access to the basin within. They plunge at once into deep water, without leaving even a platform at the water's edge wide enough for one to walk on. There are no streams tributary to the lake, and no visible outlet. The waters probably escape by percolation, as the precipitation of the region is in excess of evaporation, and if an escape were not furnished the basin would be filled to overflowing. . . .

The sounding-line has shown that Crater Lake has a maximum depth of 2,000 feet and is the deepest lake now known in North America, its nearest rival being Lake Tahoe. The full depth of the basin, measured from the crest of the enclosing cliffs, is from 2,900 to 4,200 feet. . . .

More remarkable, however, than the unique scenic features of Crater Lake is the story of its origin. The site of the great depression was once occupied by a volcanic

mountain which reached far above the highest point on the cliffs now enclosing it, and was probably as conspicuous a member of the sisterhood of mountains of which it formed a part as any of the neighboring peaks, but the once prominent pile has been removed so as to leave the profound gulf that now fascinates and startles the observer. The character of the sculpturing on the outer slope of the truncated mountain shows that it was eroded, both by streams and by glaciers, before the catastrophe that carried away its summit and left only a hollow stump to mark the site of the ice-crowned peak that formerly gleamed in the sky.—RUSSELL *Lakes of North America*, ch. 1, p. 20. (G. & Co., 1895.)

2307. MYSTERY AS TO CONSTITUTION OF THE EARTH—*An Unsolved Problem—No Dogmatism upon the Unknown.*—From this summary of the speculative views which have been entertained upon the subject of the physical condition of the earth's interior, it will be clear that at present we have not sufficient evidence for arriving at anything like a definite solution of the problem. The conditions of temperature and pressure which exist in the interior of a globe of such vast dimensions as our earth are so far removed from those which we can imitate in our experimental inquiries, and it is so unsafe to push the application of laws arrived at by the latter to the extreme limits required by the former, that we shall do well to pause before attempting to dogmatize on such a difficult question.—JUDD *Volcanoes*, ch. 11, p. 329. (A., 1899.)

2308. MYSTERY AWAITING SOLUTION—*Science Ever Looks toward the Future.*—It is believed that we understand how the more compact and stonelike variety of tuff was deposited, since similar accumulations are formed where waters saturated with calcium carbonate deposit that salt on account of the loss of carbonic acid. The dendritic tuff may also have been precipitated in a similar manner, or perhaps through the agency of low forms of plant life. The mode of origin of the tuff with well-defined crystals, however, is still unknown, altho both geologists and chemists have sought diligently to discover the secret of its formation. The open cellular structure of the crystals, as well as their forms, suggest that they are pseudomorphs: that is, having a false form, or a form not assumed by calcium carbonate on crystallizing, but resulting from the alteration or replacement of some other mineral. This suggestion only removes the difficulty one step farther, however, since the nature of the original mineral is still unknown.—RUSSELL *Lakes of North America*, ch. 6, p. 111. (G. & Co., 1895.)

2309. MYSTERY BEHIND EVOLUTION—*Cause Carried Further Back in Time.*—It [the evolutionary hypothesis] does not solve—it does not profess to solve—the ultimate mystery of this universe. It leaves, in fact, that mystery untouched. For, granting the nebula and its potential life, the question whence they came would still remain to baffle and bewilder us. At bottom the hypothesis does nothing more than "transport the conception of life's origin to an indefinitely distant past."—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 133. (A., 1897.)

2310. MYSTERY EXPLAINED—*The Sinking of Great Stones through the Action of Worms.*—Farmers in England are well aware that objects of all kinds, left on the surface of pasture-land, after a time disappear, or, as they say, work themselves downwards. How powdered lime, cinders, and heavy stones can work down, and at the same rate, through the matted roots of a grass-covered surface, is a question which has probably never occurred to them. . . . When a stone of large size and of irregular shape is left on the surface of the ground, it rests, of course, on the more protuberant parts; but worms soon fill up with their castings all the hollow spaces on the lower side; for, as Hensen remarks, they like the shelter of stones. As soon as the hollows are filled up the worms eject the earth which they have swallowed beyond the circumference of the stones, and thus the surface of the ground is raised all round the stone. As the burrows excavated directly beneath the stone after a time collapse, the stone sinks a little. Hence it is that boulders which at some ancient period have rolled down from a rocky mountain or cliff on to a meadow at its base, are always somewhat embedded in the soil: and, when removed, leave an exact impression of their lower surfaces in the underlying fine mold. If, however, a boulder is of such huge dimensions that the earth beneath is kept dry, such earth will not be inhabited by worms, and the boulder will not sink into the ground.—DARWIN *Formation of Vegetable Mould*, ch. 3, p. 42. (Hum., 1887.)

2311. MYSTERY LIES BEHIND EVERY THEORY—*Limitations of Human Mind.*—It is very frequently said, in opposition to the transmutation theory [or development hypothesis], that it does indeed fully explain those phenomena by inheritance and adaptation, but that it does not at the same time explain these properties of organic matter, and that therefore we do not arrive at first causes. This objection is quite correct, but it applies equally to all explanations of phenomena. We nowhere arrive at a knowledge of first causes. The origin of every simple salt-crystal, which we obtain by evaporating its mother-liquor, is no less mysterious to us, as far as concerns its first cause, and in itself no less incomprehensible than the origin of every animal which is developed out of a simple cell. In explaining the most simple physical or chemical phenomena, as the falling of a

stone, or the formation of a chemical combination, we arrive, by discovering and establishing the active causes—for example, the gravitation or the chemical affinity—at other remoter phenomena, which in themselves are mysterious. This arises from the limitation or relativity of our powers of understanding. We must not forget that human knowledge is absolutely limited, and possesses only a relative extension. It is, in its essence, limited by the very nature of our senses and of our brains.—HAECKEL *History of Creation*, vol. i, ch. 2, p. 31. (K. P. & Co., 1899.)

2312. MYSTERY OF CHEMICAL ACTION — *Force Apparently Inoperative or Lost—Faith in Law Leads to New Discoveries.*—It is perfectly true that we cannot always trace a force by its actions, tho we admit its conservation. Oxygen and hydrogen may remain mixed for years without showing any signs of chemical activity; they may be made at any given instant to exhibit active results, and then assume a new state, in which again they appear as passive bodies. Now, tho we cannot clearly explain what the chemical force is doing, that is to say, what are its effects during the three periods before, at, and after the active combination, and only by very vague assumption can approach to a feeble conception of its respective states, yet we do not suppose the creation of a new portion of force for the active moment of time, or the less believe that the forces belonging to the oxygen and hydrogen exist unchanged in their amount at all these periods, tho varying in their results. A part may at the active moment be thrown off as mechanical force, a part as radiant force, a part disposed of we know not how; but believing, by the principle of conservation, that it is not increased or destroyed, our thoughts are directed to search out what at all and every period it is doing, and how it is to be recognized and measured. A problem, founded on the physical truth of Nature, is stated, and, being stated, is on the way to its solution.—FARADAY *The Conservation of Force* (in *Correlation and Conservation of Forces*), p. 380. (A., 1898.)

2313. MYSTERY OF CONSCIOUSNESS—*Memory Admits of No Explanation.*—A word, in closing, about the metaphysics involved in remembering. According to the assumptions of this book, thoughts accompany the brain's workings, and those thoughts are cognitive of realities. The whole relation is one which we can only write down empirically, confessing that no glimmer of explanation of it is yet in sight. That brains should give rise to a knowing consciousness at all, this is the one mystery which returns, no matter of what sort the consciousness and of what sort the knowledge may be.—JAMES *Psychology*, vol. i, ch. 16, p. 687. (H. H. & Co., 1899.)

2314. ——— ——— *Molecular Motion Cannot Explain Thought and Feeling—Two Incomprehensibles.*—Four years ago I wrote thus: "Do states of consciousness enter as links into the chain of antecedence and sequence which gives rise to bodily actions? Speaking for myself it is certain that I have no power of imagining such states interposed between the molecules of the brain and influencing the transference of motion among the molecules. The thing "eludes all mental presentation." Hence an iron strength seems to belong to the logic which claims for the brain an automatic action uninfluenced by consciousness. But it is, I believe, admitted by those who hold the automaton theory that states of consciousness are produced by the motion of the molecules of the brain; and this production of consciousness by molecular motion is to me quite as unpresentable to the mental vision as the production of molecular motion by consciousness. If I reject one result I must reject both. *I, however, reject neither,* and thus stand in the presence of two Incomprehensibles instead of one Incomprehensible." Here I secede from the automaton theory, tho maintained by friends who have all my esteem, and fall back upon the avowal which occurs with such wearisome iteration throughout the foregoing pages; namely, my own utter incapacity to grasp the problem.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 407. (A., 1900.)

2315. ——— ——— *The All-embracing Problem—Explanations that Do Not Explain.*—Why not "pool" our mysteries into one great mystery, the mystery that brain-processes occasion knowledge at all? It is surely no different mystery to feel myself by means of one brain-process writing at this table now, and by means of a different brain-process a year hence to remember myself writing. All that psychology can do is to seek to determine what the several brain-processes are. . . . But of "images reproduced," and "claiming to represent," and "put together by a unifying *actus,*" I have been silent because such expressions either signify nothing or they are only roundabout ways of simply saying that the past is known when certain brain conditions are fulfilled, and it seems to me that the straightest and shortest way of saying that is the best.—JAMES *Psychology*, vol. i, ch. 16, p. 689. (H. H. & Co., 1899.)

2316. MYSTERY OF EVIL—*Optimism of Leibnitz—Limitation of the Divine Power—Plato Finds Matter the Source of All Evil.*—Leibnitz, in his famous theory of optimism, argued that a perfect world is in the nature of things impossible, but that the world in which we live is the best of possible worlds. The limitation of the Creator's power is made somewhat more explicitly by Plato, who regarded the world as the imperfect realization of a divine idea that in itself is perfect. It is owing to the in-

tractableness and vileness of matter that the divine idea finds itself so imperfectly realized. Thus the Creator's power is limited by the nature of the material out of which he makes the world. In other words, the world in which we live is the best the Creator could make out of the wretched material at his disposal. Matter is endowed with a diabolical character of its own.—FISKE *Through Nature to God*, pt. i, ch. 3, p. 13. (H. M. & Co., 1900.)

2317. MYSTERY OF EVOLUTION —*Is Part of the Mystery of Life—Problems Unanswered.*—The process of organic evolution is far from being fully understood. We can only suppose that as there are devised by human beings many puzzles apparently unanswerable till the answer is given, and many necromantic tricks which seem impossible till the mode of performance is shown; so there are apparently incomprehensible results which are really achieved by natural processes. Or, otherwise, we must conclude that since life itself proves to be in its ultimate nature inconceivable, there is probably an inconceivable element in its ultimate workings.—SPENCER *Biology*, pt. iii, ch. 14A, p. 574. (A., 1900.)

2318. MYSTERY OF EXTENDED CONSCIOUSNESS—*Feeling through Tools and Implements.*—With the point of a cane we can trace letters in the air or on a wall just as with the finger-tip, and in so doing feel the size and shape of the path described by the cane's tip just as immediately as, without a cane, we should feel the path described by the tip of our finger. Similarly the draftsman's immediate perception seems to be of the point of his pencil, the surgeon's of the end of his knife, the duelist's of the tip of his rapier as it plunges through his enemy's skin. When on the middle of a vibrating ladder, we feel not only our feet on the round, but the ladder's feet against the ground far below. If we shake a locked iron gate we feel the middle, on which our hands rest, move, but we equally feel the stability of the ends where the hinges and the lock are, and we seem to feel all three at once. And yet the place where the contact is received is in all these cases the skin, whose sensations accordingly are sometimes interpreted as objects on the surface, and at other times as objects a long distance off.—JAMES *Psychology*, vol. ii, ch. 17, p. 37. (H. H. & Co., 1899.)

2319. MYSTERY OF FLIGHT—*Seeming Defiance of Gravitation.*—"The way of an eagle in the air" was one of the things of which Solomon said that "he knew it not." No wonder that the wise king reckoned it among the great mysteries of Nature! The force of gravitation, tho its exact measure was not ascertained till the days of Newton, has been the most familiar of all forces in all ages of mankind. How, then, in violation of its known effects could heavy bodies be supported upon the thin air, and be gifted with the power of sustaining and directing movements more easy, more rapid, and more certain than the movements of other animals upon the firm and solid earth? No animal motion in Nature is so striking or so beautiful as the

> Scythe-like sweep of wings, that dare
> The headlong plunge through eddying gulfs of air.
> —LONGFELLOW, *Wayside Inn.*

Nor will the wonder cease when, so far as the mechanical problem is concerned, the mystery of flight is solved. If we wish to see how material laws can be bent to purpose, we shall study this problem.—ARGYLL *Reign of Law*, ch. 3, p. 77. (Burt.)

2320. MYSTERY OF GEOLOGY—*Lake of Unexplained Origin—We Find It Amid the Mountains—Lake Basin Once the Bed of a Glacier.*—The sounding-line has shown that Lake Chelan is over eleven hundred feet deep, but its full depth remains to be determined. In several soundings made by the writer in its central and western portions, no bottom was reached at the depth indicated. The surface of the lake is but 950 feet above the sea, so that the bottom of the trough is below sea-level. . . .

How the great gash in the mountain, fully one hundred miles long, and now filled for more than a thousand feet in depth by the lake, was formed is not easy to explain. Previous to the birth of the present lake the valley was occupied by a large glacier which flowed through it and joined another great ice-stream in the cañon of the Columbia. The ice smoothed the precipices of rock and piled up moraines on the more gentle slopes at the east end of the valley, but that the main depression existed before the glacial invasion is evident and is in harmony with the histories of many other valleys in the Cordilleran region. The valley has a still more ancient history, and in Tertiary, or in part perhaps in pre-Tertiary times, was excavated in the hard granite, now seen in its enclosing walls by the slow wear of streams. It is a stream-cut channel, but where the stream rose that did the work, or whence it flowed, remains to be determined by a careful study of all the facts bearing on the problem.—RUSSELL *Lakes of North America*, ch. 4, p. 66. (G. & Co., 1895.)

2321. MYSTERY OF GLACIAL EPOCH—We have as yet no clue to the source of this great and sudden change of climate [that produced the Glacial epoch]. Various suggestions have been made, among others that formerly the inclination of the earth's axis was greater, or that a submersion of the continents under water might have produced a decided increase of cold; but none of these explanations are satisfactory, and science has yet to find any cause which accounts for all the phenomena connected with it. It seems, however, unquestionable that since the opening of the Tertiary Age a cosmic summer and winter have succeeded each other, during which a

tropical heat and an arctic cold have alternately prevailed over a great portion of the present temperate zone.—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 210. (H. M. & Co., 1896.)

2322. ——— ——— The different explanations of this wide-spread refrigeration [of the Glacial epoch] are stated and briefly discussed. To account for it seems to me, in the present state of our knowledge, the most perplexing of all the problems which this epoch presents. — BONNEY *Ice-work, Present and Past*, pref., p. 9. (A., 1896.)

2323. MYSTERY OF HEREDITY—In the case of self-division, where the whole organism falls into two halves, in the formation of buds, where a considerable portion of the whole body, already more or less developed, separates from the producing individual, we easily understand that the forms and vital phenomena should be the same in the producing and produced organism. It is much more difficult to understand in the formation of germ-buds, and more difficult still in the formation of germ-cells, how this very small, quite undeveloped portion of the body, this group of cells, or this single cell, not only directly takes with it certain parental qualities into its independent existence, but also after its separation from the parental individual develops into a many-celled body, and in this repeats the forms and vital phenomena of the original producing organism.—HAECKEL *History of Creation*, vol. i, ch. 8, p. 199. (K. P. & Co., 1899.)

2324. MYSTERY OF INTERACTION OF MIND AND BRAIN—*Incorporation of the Two Impossible—Succession in Time—Interchange of Subject and Object.*—When, therefore, we talk of incorporating mind with brain we must be held as speaking under an important reserve or qualification. Asserting the union in the strongest manner, we must yet deprive it of the almost invincible association of union in place. An extended organism is the condition of our passing into a state where there is no extension. A human being is an extended and material mass, attached to which is the power of becoming alive to feeling and thought, the extreme remove from all that is material; a condition of trance wherein, while it lasts, the material drops out of view—so much so that we have not the power to represent the two extremes as lying side by side, as container and contained, or in any other mode of local conjunction. The condition of our existing thoroughly in the one is the momentary eclipse or extinction of the other.—BAIN *Mind and Body*, ch. 6, p. 34. (Hum., 1880.)

2325. MYSTERY OF LIFE—*Scientific Explanation Often Mere Restatement.*—Not to speak of the connection of the body and the mind, not to speak of the nature of life, or still more of the nature of death, the simplest questions connected with our own organization are unanswered and unanswerable. Science gives us no help, because the explanations which to it are ultimate are not ultimate at all to the faculties which seek for more light concerning them. The very language of science is, in this respect, often more deceptive than helpful, inasmuch as it is the fashion of scientific men to pass off as explanations the mere restatement of facts concealed under words derived from the dead languages. Perhaps it is all that they can do; but at least the poverty of the device should be seen and known. The "atoms" and the "molecules," the "cells" and the "differentiated structures," are these the builders, or are they only the bricks and stones? And the forces and the energies which work in these and upon these, what are they? And if these are undying and inexhaustible, how are all the forms in which they are embodied so fugitive and evanescent?—ARGYLL *Unity of Nature*, ch. 4, p. 77. (Burt.)

2326. MYSTERY OF LIGHT—*Its Motion Incomprehensible.*—What is the essential nature of light? How do we see the universe? How does a luminous body radiate, and by what vehicle do its rays reach our eyes? What are even these rays? Man has discussed this great problem for thousands of years. The ancients believed that the rays might be shot forth from our eyes to lay hold of objects far away; Newton thought, on the contrary, that objects emitted luminous particles which pass through space and strike our retina; Young and Fresnel have since shown that luminous bodies do not emit any material particle, but cause the surrounding fluid to vibrate, as a bell makes the air vibrate. This has led us to imagine as indispensable to the propagation of light a certain fluid named ether, which is extremely light, and disseminated through the whole of space.

Just as we see the circular waves of a piece of water succeed each other round the point where the water has been struck, as air condenses and dilates in spherical waves round the resounding tuning-fork, so the ethereal fluid which fills space gives birth to a series of spherical waves, succeeding each other all round a luminous body. The waves of water are transmitted so slowly that the eye easily follows their motion; those of air fly with the velocity of 1,100 feet per second, varying with the temperature and the density of the atmosphere; those of the ether pass through immensity with the dizzy velocity of 186,000 miles per second. The most marvelous fact is that every star, every sun in space, is the center of constant undulations, which thus perpetually cross each other through immensity, without ever being confused or mutually mingled. I confess, for my part, that this fact appears to me absolutely incomprehensible. — FLAMMARION *Popular Astronomy*, bk. iii, ch. 7, p. 316. (A.)

2327. MYSTERY OF ROENTGEN RAYS—*Their Nature Unexplained—Defy Refraction or Reflection.*—What is it that constitutes the difference between the Roentgen rays and rays of ordinary light in consequence of which the one are not refracted, or only in an infinitesimal degree, while the other are freely refracted? . . . How is it that light travels more slowly through refracting medium than through vacuum? There are different conjectures which have been advanced. One is that the ether within refracting media is more dense than the ether in free space. Another is that while the density is the same the elasticity is less. Then, there have been speculations as to the ether being loaded with particles of matter. —G. G. STOKES, quoted by BARKER in *Roentgen Rays*, essay 4, p. 58. (H., 1899.)

2328. MYSTERY OF SLEEP—*Awe-inspiring Contrast to Waking Life.*—There is the mystery of sleep, which quietly shuts all the avenues of sense and so isolates the mind from contact with the world outside. To gaze at the motionless face of a sleeper temporarily rapt from the life of sight, sound, and movement—which, being common to all, binds us together in mutual recognition and social action—has always something awe-inspiring. This external inaction, this torpor of sense and muscle, how unlike to the familiar waking life, with its quick responsiveness and its overflowing energy!—SULLY *Illusions*, ch. 7, p. 127. (A., 1897.)

2329. MYSTERY OF THE SEAT OF THE SOUL—*Relation of Consciousness to Space.*—This is the problem known in the history of philosophy as the question of the seat of the soul. It has given rise to much literature, but we must ourselves treat it very briefly. Everything depends on what we conceive the soul to be, an extended or an inextended entity. . . .

The truth is that if the thinking principle is extended we neither know its form nor its seat, whilst if unextended it is absurd to speak of its having any space-relations at all.—JAMES *Psychology*, vol. i, ch. 8, p. 214. (H. H. & Co., 1890.)

2330. MYSTERY OF THE SUN'S CORONA—*Spectroscope Fails to Solve—Finds There a Yet Unknown Gas.*—The spectroscope informs us that, in great part at least, the elements which exist in the lower regions of the solar atmosphere in the state of vapor are metals we are familiar with upon the earth, while it shows the chromosphere and prominences to consist mainly of hydrogen and helium, and makes it possible to observe them even when the sun is not hidden by the moon. The secret of the corona it fails to unlock as yet, tho it informs us of the presence in it of an unknown gas of inconceivable tenuity.—YOUNG *The Sun*, int., p. 8. (A., 1898.)

2331. MYSTERY OF THE SUN'S UPLIFTING POWER—*Plants Built Up in Defiance of Gravitation.*—Did the reader ever consider that next to the mystery of gravitation, which draws all things on the earth's surface down, comes that mystery—not seen to be one because so familiar—of the occult force in the sunbeams which lifts things up? The incomprehensible energy of the sunbeam brought the carbon out of the air, put it together in the weed or the plant, and lifted each tree-trunk above the soil. The soil did not lift it, any more than the soil in Broadway lifted the spire of Trinity. Men brought stones there in wagons to build the church, and the sun brought the materials in its own way, and built up alike the slender shaft that sustains the grass-blade and the column of the pine. If the tree or the spire fell it would require a certain amount of work of men or horses or engines to set it up again. So much actual work, at least, the sun did in the original building, and if we consider the number of trees in the forest we see that this alone is something great.—LANGLEY *New Astronomy*, ch. 3, p. 72. (H. M. & Co., 1896.)

2332. MYSTERY OF THE UNIVERSE—*One or Many Systems?*—Is the visible universe organized in one or in several systems? . . . A problem so vast as this is still far from receiving even an approximate solution. From whatever point of view we consider it we find ourselves face to face with the infinite in space and time. The present aspect of the universe immediately brings into question its past and its future state, and then the whole of united human learning supplies us in this great research with but a pale light scarcely illuminating the first steps of the dark and unknown road on which we are traveling.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 10, p. 652. (A.)

2333. MYSTERY OF VOLCANO AND EARTHQUAKE—*Boundary of Darkness around Circle of Light.*—I shall endeavor to point out . . . that the general tendency of subterranean movements, when their effects are considered for a sufficient lapse of ages, is eminently beneficial, and that they constitute an essential part of that mechanism by which the integrity of the habitable surface is preserved, and the very existence and perpetuation of dry land secured. Why the working of this same machinery should be attended with so much evil is a mystery far beyond the reach of our philosophy, and must probably remain so until we are permitted to investigate, not our planet alone and its inhabitants, but other parts of the moral and material universe with which they may be connected. Could our survey embrace other worlds, and the events, not of a few centuries only, but of periods as indefinite as those with which geology renders us familiar, some apparent contradictions might be reconciled, and some difficulties would doubtless be cleared up. But even then, as our capacities are finite,

while the scheme of the universe may be infinite, both in time and space, it is presumptuous to suppose that all sources of doubt and perplexity would ever be removed. On the contrary, they might, perhaps, go on augmenting in number, altho our confidence in the wisdom of the plan of Nature should increase at the same time; for it has been justly said that the greater the circle of light the greater the boundary of darkness by which it is surrounded.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 493. (A., 1854.)

2334. MYSTERY REMAINS EVEN TO THE MONIST—*The Riddle of the Universe Unread.*—We grant at once that the innermost character of Nature is just as little understood by us as it was by Anaximander and Empedocles twenty-four hundred years ago, by Spinoza and Newton two hundred years ago, and by Kant and Goethe one hundred years ago. We must even grant that this essence of substance becomes more mysterious and enigmatic the deeper we penetrate into the knowledge of its attributes, matter and energy, and the more thoroughly we study its countless phenomenal forms and their evolution. We do not know the "thing in itself" that lies behind these knowable phenomena.—HAECKEL *Riddle of the Universe*, concl., p. 380. (H., 1900.)

2335. MYSTERY, SCIENTIFIC — *A Zone of Darkness—The Unknown Everywhere Surrounds the Known.*—Lest this proclamation of mystery should seem alarming, let us add that this mystery also is scientific. The one subject on which all scientific men are agreed, the one theme on which all alike become eloquent, the one strain of pathos in all their writing and speaking and thinking, concerns that final uncertainty, that utter blackness of darkness bounding their work on every side. If the light of Nature is to illuminate for us the spiritual sphere, there may well be a black unknown, corresponding, at least at some points, to this zone of darkness round the natural world.—DRUMMOND *Natural Law in the Spiritual World*, int., p. 25. (H. Al.)

2336. MYSTERY SOLVED — *Comets' Tails Not Ethereal, but Subject to Ordinary Laws of Matter.*—The mystery of comets' tails has been to some extent penetrated; so far, at least, that by making certain assumptions strongly recommended by the facts of the case their forms can be, with very approximate precision, calculated beforehand. We have, then, the assurance that these extraordinary appendages are composed of no ethereal or supersensual stuff, but of matter such as we know it, and subject to the ordinary laws of motion, tho in a state of extreme tenuity. This is unquestionably one of the most remarkable discoveries of our time.—CLERKE *History of Astronomy*, pt. ii, ch. 11, p. 417. (Bl., 1893.)

2337. ——— ——— *Electric Repulsion the Producing Cause of Comets' Tails—Conflict of Forces.*—It is perfectly well ascertained that the energy of the push or pull produced by electricity depends (other things being the same) upon the *surface* of the body acted on; that of gravity upon its *mass*. The efficacy of solar electrical repulsion relatively to solar gravitational attraction grows, consequently, as the size of the particle diminishes. Make this small enough, and it will virtually cease to gravitate, and will unconditionally obey the impulse to recession. This principle Zöllner was the first to realize in its application to comets. It gives the key to their constitution. Admitting (as we seem bound to do) that the sun and they are similarly electrified, their more substantially aggregated parts will still follow the solicitations of his gravity, while the finely divided particles escaping from them will, simply by reason of their minuteness, fall under the sway of his repellent electric power. They will, in other words, form "tails." Nor is any extravagant assumption called for as to the intensity of the electrical charge concerned in producing these effects. Zöllner, in fact, showed that it need not be higher than that attributed by the best authorities to the terrestrial surface.—CLERKE *History of Astronomy*, pt. ii, ch. 11, p. 418. (Bl., 1893.)

2338. ——— ——— *Hospitals No Longer Charnel-houses—Exclusion of Bacteria Helps Surgeon and Patient.*—It was these organisms [bacteria] acting in wound and abscess which so frequently converted our hospitals into charnel-houses, and it is their destruction by the antiseptic system that now renders justifiable operations which no surgeon would have attempted a few years ago. The gain is immense to the practising surgeon as well as to the patient practised upon. Contrast the anxiety of never feeling sure whether the most brilliant operation might not be rendered nugatory by the access of a few particles of unseen hospital-dust, with the comfort derived from the knowledge that all power of mischief on the part of such dust has been surely and certainly annihilated.—TYNDALL *Floating Matter of the Air*, essay 5, p. 287. (A., 1895.)

2339. MYSTERY SURROUNDS FACTS OF SCIENCE—*The Great Ice Age Unexplained.*—It follows [from previous explanations] that the low temperature which undoubtedly prevailed during the Glacial Epoch has not yet received any satisfactory explanation. Each one that has been proposed is either inadequate or attended by grave difficulties. It is therefore probable that some factor which is essential for the complete solution of the problem is as yet undiscovered, or, at any rate, the importance of one which is already known has

not been duly recognized.—BONNEY *Ice-work, Present and Past*, pt. iii, ch. 2, p. 260. (A., 1896.)

2340. MYSTERY UNEXPLAINED—*Darwin's Conjecture Unfounded—The Eucalyptus on South-American Pampas.*—Scientists have not yet been able to explain why the pampas, with a humid climate and a soil exceedingly rich, have produced nothing but grass, while the dry, sterile territories on their north, west, and south borders have an arborescent vegetation. Darwin's conjecture that the extreme violence of the pampero, or southwest wind, prevented trees from growing, is now proved to have been ill-founded since the introduction of the *Eucalyptus globulus;* for this noble tree attains to an extraordinary height on the pampas, and exhibits there a luxuriance of foliage never seen in Australia.—HUDSON *Naturalist in La Plata*, ch. 1, p. 4. (C. & H., 1895.)

2341. MYSTERY UNFATHOMABLE—*Distances of Few Stars Known—Most Forever Unknown.*—Even the mighty instruments of our own day, wielded with all the skill and acumen which a long experience has generated, have not sufficed to enable us to measure the distances of more than about a dozen stars. Nor probably will it ever be possible for man to count by the hundred the number of stars whose distances are known. Of all the millions of stars revealed by the telescope, not the ten-thousandth part will have their true position in space assigned to them, however roughly. The real architecture of the stellar system must remain forever unknown to us, except as respects a relatively minute portion lying within certain limits of distance from the earth.—PROCTOR *Our Place among Infinities*, p. 188. (L. G. & Co., 1897.)

2342. MYTHOLOGY APPROPRIATED ANCIENT VOLCANOES—*The Forge of Vulcan.*—The ancients were acquainted only with the four or five active volcanoes in the Mediterranean area, the term "volcano" being the name of one of these (Vulcano, or Volcano, in the Lipari Islands), which has come to be applied to all similar phenomena. It is only in comparatively modern times that it has become a known fact that many hundreds of volcanoes exist upon the globe, and are scattered over almost every part of its surface. Classical mythology appropriated Vulcano as the forge of Hephæstus, and his Roman representative Vulcan, while Etna was regarded as formed by the mountains under which the vengeful deity had buried the rebellious Typhon; it may be imagined, therefore, that any endeavor to more closely investigate the phenomena displayed at these localities would be regarded not simply as an act of temerity, but as one of actual impiety.—JUDD *Volcanoes*, ch. 1, p. 3. (A., 1899.)

2343. MYTHOLOGY OF GREEKS—*The Simplicity of Nature Spoiled—Sense of Natural Beauty Fitfully Expressed.*—The Greek regarded the vegetable world as standing in a manifold and mythical relation to heroes and to the gods, who were supposed to avenge every injury inflicted on the trees and plants sacred to them. Imagination animated vegetable forms with life, but the types of poetry to which the peculiar direction of mental activity among the ancient Greeks limited them gave only a partial development to the descriptions of natural scenery. Occasionally, however, even in the writings of their tragic poets, a deep sense of the beauty of Nature breaks forth in animated descriptions of scenery in the midst of the most excited passions or the deepest tones of sadness. Thus, when Œdipus is approaching the grove of the Eumenides, the chorus sings, "the noble resting-place of the illustrious Colonos, where the melodious nightingale loves to tarry and pour forth its clear but plaintive note." Again it sings, "the verdant gloom of the thickly mantling ivy, the narcissus steeped in heavenly dew, the golden-beaming crocus, and the hardy and ever fresh-sprouting olive-tree." Sophocles strives to extol his native Colonos by placing the lofty form of the fated and royal wanderer by the brink of the sleepless waters of Cephisus, surrounded by soft and bright scenery. The repose of Nature heightens the impression of pain called forth by the image of the noble form of the blind sufferer, the victim of mysterious and fatal passion. Euripides also delights in picturesque descriptions of "the pastures of Messenia and Laconia, which, under an ever-mild sky, are refreshed by a thousand fountains and by the waters of the beautiful Pamisos."—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 25. (H., 1897.)

2344. MYTHS, DISAPPEARANCE OF, NO LOSS—*Science Makes Nature Not Less Grand—A Higher Poetry and a Mightier Philosophy.*—To a right-thinking and right-feeling mind, the beauty, the grandeur, the mystery of Nature are augmented, not lessened, by each new glimpse into the secret recesses of her operations. The sun going forth from its chamber in the east to run its course is not less glorious in majesty because we have discovered the law of gravitation, and are able by spectral analysis to detect the metals which enter into its composition—because it is no longer Helios driving his golden chariot through the pathless spaces of the heavens. The mountains are not less imposing in their grandeur because the oreads have deserted them, nor the groves less attractive nor the streams more desolate because science has banished the dryads and the naiads. No, science has not destroyed poetry, nor expelled the divine from Nature, but has furnished the materials and given the presages of a higher poetry and a mightier philosophy than the world has yet seen. The grave of each superstition which it slays is the womb of a better birth. And if it come

to pass in its onward march—as it may well be it will come to pass—that other superstitions shall be dethroned as the sun-god has been dethroned, we may rest assured that this also will be a step in human progress and in the beneficent evolution of the Power which ruleth alike the courses of the stars and the ways of men.—MAUDSLEY *Body and Mind*, lect. 3, p. 96. (A., 1898.)

2345. MYTHS, MODERN, MATCHING ANCIENT—*The Odyssey Finds Parallel in New Zealand.*—The Tahitians tell tales of their sea-god Hiro, whose followers were sailing on the ocean while he was lulled to sleep in a cavern in the depths below; then the wind-god raised a furious storm to destroy the canoe, but the sailors cried to Hiro, till, rising to the surface, he quelled the storm, and his votaries came safe to port. So in Homer, Poseidon the sea-god, dweller in caves of ocean, sets on the winds to toss the frail bark of Odysseus among the thundering waves, till Ino comes to his rescue and bids him strip and swim for the Phaiakian shore. Both tales are word-pictures of the stormy sea told in the language of nature-myths, only with different turns. The New Zealanders have a story of Maui imprisoning the winds, all but the wild west wind, whom he cannot catch to shut into its cavern by a great stone rolled against its mouth; all he can do is to chase it home sometimes, and then it hides in the cavern and for a while dies away. All this is a mythic description of the weather, meaning that other winds are occasional, but the west wind prevalent and strong. These New Zealanders had never heard of the classic myth of Æolus and the cave of the winds, yet how nearly they had come to the same mythic fancy, that it is from such blowholes in the hillsides that the winds come forth.—TYLOR *Anthropology*, ch. 15, p. 392. (A., 1899.)

2346. MYTHS OF ZOOLOGY—*Hairworms—Toads in Rock—Barnacle Geese—Popular Credulity Unlimited.*—When the country swain, loitering along some lane, comes to a standstill to contemplate, with awe and wonder, the spectacle of a mass of the familiar "hair-eels" or "hairworms" wriggling about in a pool, he plods on his way firmly convinced that, as he has been taught to believe, he has just witnessed the results of the transformation of some horse's hairs into living creatures. So familiar is this belief to people of professedly higher culture than the countryman, that the transformation just alluded to has to all, save a few thinking persons and zoologists, become a matter of the most commonplace kind. When some quarrymen, engaged in splitting up the rocks, have succeeded in dislodging some huge mass of stone, there may sometimes be seen to hop from among the débris a lively toad or frog, which comes to be regarded by the excavators with feelings akin to those of superstitious wonder and amazement. The animal may or may not be captured; but the fact is duly chronicled in the local newspapers, and people wonder for a season over the phenomenon of a veritable Rip Van Winkle of a frog, which, to all appearance, has lived for "thousands of years in the solid rock." Nor do the hairworm and the frog stand alone in respect of their marvelous origin. Popular zoology is full of such marvels. We find unicorns, mermaids, and mermen; geese developed from the shell-fish known as "barnacles"; we are told that crocodiles may weep, and that sirens can sing—in short, there is nothing so wonderful to be told of animals that people will not believe the tale.—ANDREW WILSON *Facts and Fictions of Zoology*, p. 1. (Hum., 1882.)

2347. ——— ——— *Ludicrous Fiction about the Skunk.*—In that not always trustworthy book, "The Natural History of Chili," Molina tells us how they deal with the animal in the transandine regions. "When one appears," he says, "some of the company begin by caressing it, until an opportunity offers for one of them to seize it by the tail. In this position the muscles become contracted, the animal is unable to eject its fluid, and is quickly despatched." One might just as well talk of caressing a cobra de capello; yet this laughable fiction finds believers all over South and North America. Professor Baird gravely introduces it into his great work on the mammalia. . . . The Indians are grave jokers, they seldom smile; and this old traditional skunk-joke, which has run the length of a continent, finding its way into many wise books, is their revenge on a superior race.—HUDSON *Naturalist in La Plata*, ch. 6, p. 118. (C. & H., 1895.)

2348. ——— ——— *Romantic Tales of the Gorilla—Inventions to Amuse Children.*—Mr. Ford discredits the house-building and elephant-driving stories [viz.: that the gorillas build houses to live in, and that bands of them unite, arm themselves with clubs, and drive elephants through the forest], and says that no well-informed natives believe them. They are tales told to children.—HUXLEY *Man's Place in Nature*, p. 212. (Hum.)

2349. ——— ——— *South-American Legend of a Tree-creeper's Nest.*—One species, *Erythrothorax*, in Yucatan, makes so large a nest of sticks, that the natives do not believe that so small a bird can be the builder. They say that when the *tzapatan* begins to sing, all the birds in the forest repair to it, each one carrying a stick to add to the structure; only one, a tyrant-bird, brings two sticks, one for itself and one for the *urubû* or vulture, that bird being considered too large, heavy, and ignorant of architecture to assist personally in the work.—HUDSON *Naturalist in La Plata*, ch. 18, p. 245. (C. & H., 1895.)

2350. MYTHS, ORIGIN OF—*Imagination among Barbarians—Supposed Remains of Giants.*—We know how strong our own desire is to account for everything. This desire is as strong among barbarians, and accordingly they devise such explanations as satisfy their minds. But they are apt to go a stage further, and their explanations turn into the form of stories with names of places and persons, thus becoming full-made myths. Educated men do not now consider it honest to make fictitious history in this way, but people of untrained mind, in what is called the myth-making stage, which has lasted on from the savage period and has not quite disappeared among ourselves, have no such scruples about converting their guesses at what may have happened into the most lifelike stories of what they say did happen. Thus, when comparative anatomy was hardly known, the finding of huge fossil bones in the ground led people to think they were the remains of huge beasts and enormous men, or giants, who formerly lived on the earth. Modern science decides that they were right as to the beasts, which were ancient species of elephant, rhinoceros, etc., but wrong as to the giants, none of the great bones really belonging to any creature like man. But while the belief lasted that they were bones of giants, men's imagination worked in making stories about these giants and their terrific doings, stories which are told still in all quarters of the globe as tho they were traditions of real events.—TYLOR *Anthropology*, ch. 15, p. 388. (A., 1899.)

2351. ——— ——— *Observer Held To Be Ruler of the Winds—Æolus Made a God.*—In the Lipari Islands there has prevailed a belief, from the very earliest period of history, that the feeble eruptions of Stromboli are in some way dependent upon the condition of the atmosphere. These islands were known to the ancients as the Æolian Isles, from the fact that they were once ruled over by a king of the name of Æolus. It seems not improbable that Æolus was gifted with natural powers of observation and reasoning far in advance of those of his contemporaries. A careful study of the vapor-cloud which covers Stromboli would certainly afford him information concerning the hygrometric condition of the atmosphere; the form and position assumed by this vapor-cloud would be a no less perfect index of the direction and force of the wind; and, if the popular belief be well founded, the frequence and violence of the explosions taking place from the crater would indicate the barometric pressure. From these data an acute observer would be able to issue "storm-warnings" and weather prognostics of considerable value. In the vulgar mind, the idea of the prediction of natural events is closely bound up with that of their production; and the shrewd weather-prophet of Lipari was after his death raised to the rank of a god, and invested with the sovereignty of the winds.—JUDD *Volcanoes*, ch. 2, p. 34. (A., 1899.)

2352. NAME, IMPORTANCE OF—*Science and Morality Unite—Redemption of the Drunkard.*—The hackneyed example of moral deliberation is the case of an habitual drunkard under temptation. He has made a resolve to reform, but he is now solicited again by the bottle. His moral triumph or failure literally consists in his finding the right name for the case. If he says that it is a case of not wasting good liquor already poured out, or a case of not being churlish and unsociable when in the midst of friends, or a case of learning something at last about a brand of whisky which he never met before, or a case of celebrating a public holiday, or a case of stimulating himself to a more energetic resolve in favor of abstinence than any he has ever yet made, then he is lost. His choice of the wrong name seals his doom. But if, in spite of all the plausible good names with which his thirsty fancy so copiously furnishes him, he unwaveringly clings to the truer bad name, and apperceives the case as that of "being a drunkard, being a drunkard, being a drunkard," his feet are planted on the road to salvation. He saves himself by thinking rightly.—JAMES *Talks to Teachers*, ch. 15, p. 187. (H. H. & Co., 1900.)

2353. NARROWNESS OF SPECIALIST—*Specialty Disqualifies for Comprehensive Reasonings.*—Science has in the course of its growth become divided into a great number of small specialties, each pursued ardently by its own votaries. This is beneficial in one respect; for much more can be gained by men digging downward, each on his own vein of valuable ore, than by all merely scraping the surface. But the specialist, as he descends fathom after fathom into his own mine, however rich and rare the gems and metals he may discover, becomes more and more removed from the ordinary ways of men, and more and more regardless of the products of other veins as valuable as his own. The specialist, however profound he may become in the knowledge of his own limited subject, is on that very account less fitted to guide his fellow men in the pursuit of general truth. When he ventures to the boundaries between his own and other domains of truth, or when he conceives the idea that his own little mine is the sole deposit of all that requires to be known, he sometimes makes grave mistakes; and these pass current for a time as the dicta of high scientific authority.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 17. (A. B. P. S.)

2354. NATION GREATER THAN COUNTRY—*Power and Influence of the Danes.*—Denmark occupies a larger space in the history than on the map of Europe; the nation is greater than the country. With the growth of physical power in surrounding populations, she has lost much of her influ-

ence in political councils, and has been recently deprived of a great part of her ancient possessions, but the Danes of to-day are no unworthy representatives of their ancestors. Many a larger nation might envy them the position they hold in science and art, and few have contributed more to the progress of human knowledge. Copenhagen may well be proud both of her museums and of her professors, and I would especially point to the celebrated Museum of Northern Antiquities as being most characteristic and unique.—AVEBURY *Prehistoric Times,* ch. 7, p. 213. (A., 1900.)

2355. NATURALISTS HAD REASONS FOR DENYING DEEP-SEA LIFE—*Fact Contradicts Reasonable Theory.*—It is not surprising that the naturalists of the early part of the present century could not believe in the existence of a fauna at the bottom of the deep seas. The extraordinary conditions of such a region—the enormous pressure, the absolute darkness, the probable absence of any vegetable life from want of direct sunlight—might very well have been considered sufficient to form an impassable barrier to the animals migrating from the shallow waters and to prevent the development of a fauna peculiarly its own.—HICKSON *Fauna of the Deep Sea,* ch. 2, p. 17. (A., 1894.)

2356. NATURE A COSMOS—*The Study of Ages.*—He who can trace, through bygone times, the stream of our knowledge to its primitive source, will learn from history how, for thousands of years, man has labored, amid the ever-recurring changes of form, to recognize the invariability of natural laws; and has thus, by the force of mind, gradually subdued a great portion of the physical world to his dominion. In interrogating the history of the past, we trace the mysterious course of ideas yielding the first glimmering perception of the same image of a cosmos, or harmoniously ordered whole, which, dimly shadowed forth to the human mind in the primitive ages of the world, is now fully revealed to the maturer intellect of mankind as the result of long and laborious observation.—HUMBOLDT *Cosmos,* vol. i, int., p. 23. (H., 1897.)

2357. NATURE AIDS INDUSTRIES—*Native Copper Waiting for Primitive Man to Pick Up.*—In the neighborhood of Lake Superior, and in some other still more northern localities, copper is found native in large quantities, and the Indians had therefore nothing to do but to break off pieces and hammer them into the required shape. Hearne's celebrated journey to the mouth of the Coppermine River, under the auspices of the Hudson's Bay Company, was undertaken in order to examine the locality whence the natives of that district obtained the metal. In this case it occurred in lumps actually on the surface, and the Indians seem to have picked up what they could, without attempting anything that could be called mining.—AVEBURY *Prehistoric Times,* ch. 8, p. 243. (A., 1900.)

2358. NATURE AN ARMORY—*Invariable Law Admits of Varying Adjustment—Will, Contrivance, and Purpose Find Place.*—Nature is a great armory of weapons and implements for the service and the use of will. Many of them are too ponderous for man to wield. He can only look with awe on the tremendous forces which are everywhere seen yoked under the conditions of adjustment—on the smoothness of their motions—on the magnitude and the minuteness, on the silence and the perfection, of their work. But there are also many weapons hung upon the walls which lend themselves to human hands—lesser tools which man can use. He cannot alter or modify them in shape or pattern, in quality or in power. The fashion of them and the nature of them are fixed forever. These are, indeed, invariable. Only if we know how to use them, then that use is ours. Then also the lesser contrivances which we can set in motion are ever found to work in perfect harmony with the vaster mechanisms which are moving overhead. And as in the material world no effort gives so fully the sense of work achieved as the subjugation of some natural force under the command of will, so in the world of mind no triumphs of the spirit are happier than those by which some natural tendency of human character is led to the accomplishment of a purpose which is wise and good.—ARGYLL *Reign of Law,* ch. 7, p. 227. (Burt.)

2359. NATURE ANTICIPATES HUMAN INVENTION—*The Bees Invented Canning.*—With their honey-cells sealed airtight, into which some observers believe that a drop of formic acid is injected, the bee folk were actually the first in the world to found a canning factory.—GLOCK *Die Symbolik der Bienen,* p. 20. (Translated for *Scientific Side-Lights.)*

2360. "NATURE" A PSEUDONYM FOR GOD—*An Intelligent Creative Mind.*—An able writer of the agnostic school, in a popular lecture on coal, . . . apostrophizes "Nature" as the cunning contriver who stored up this buried sunlight by her strange and mysterious alchemy, kept it quietly to herself through all the long geological periods when reptiles and brute mammals were lords of creation, and through those centuries of barbarism when savage men roamed over the productive coal-districts in ignorance of their treasures, and then revealed her long-hidden stores of wealth and comfort to the admiring study of science and civilization, and for the benefit of the millions belonging to densely peopled and progressive nations. It is plain that "Nature" in such a connection represents either a poetical fiction, a superstitious fancy, or an intelligent creative mind. It is further evident that such creative mind

must be in harmony with that of man, tho vastly greater in its scope and grasp in time and space.—DAWSON *Facts and Fancies in Modern Science*, lect. 5, p. 182. (A. B. P. S.)

2361. NATURE, BEAUTY AND VARIETY OF—*Natural Selection Not an Explanation.*—Now, what explanation does the law of natural selection give—I will not say of the origin, but even of the continuance and preservation—of such specific varieties as these [of humming-birds]? None whatever. A crest of topaz is no better in the struggle for existence than a crest of sapphire. A frill ending in spangles of the emerald is no better in the battle of life than a frill ending in the spangles of the ruby. A tail is not affected for the purposes of flight, whether its marginal or its central feathers are decorated with white. It is impossible to bring such varieties into relation with any physical law known to us. It has relation, however, to a purpose, which stands in close analogy with our own knowledge of purpose in the works of man. Mere beauty and mere variety, for their own sake, are objects which we ourselves seek when we can make the forces of Nature subordinate to the attainment of them. There seems to be no conceivable reason why we should doubt or question that these are ends and aims also in the forms given to living organisms, when the facts correspond with this view, and with no other. In this sense we can trace a creative law; that is, we can see that these forms of life do fulfil a purpose and intention which we can appreciate and understand.—ARGYLL *Reign of Law*, ch. 5, p. 139. (Burt.)

2362. NATURE, CALM OF, DELUSIVE—*Quiet Intervals of Volcanoes.*—While the volcano Stromboli (Strongyle) has been incessantly active since the Homeric ages, and has served as a beacon-light to guide the mariner in the Tyrrhenian Sea, loftier volcanoes have been characterized by long intervals of quiet. Thus we see that a whole century often intervenes between the eruptions of most of the colossi which crown the summits of the Cordilleras of the Andes.—HUMBOLDT *Cosmos*, vol. i, p. 229. (H., 1897.)

2363. NATURE DOES NOT EXPLAIN MAN—A glance at our logical behavior demonstrates that we cannot find the clue to human nature by considering man from the standpoint of natural science alone. Man is more than merely a product of Nature. An inner principle, the spiritual norm, following special laws of their own, are also determining factors.—SCHWARZ *Psychologie des Willens (a Lecture)*. (Translated for *Scientific Side-Lights.)*

2364. NATURE, EXTERNAL—*Perception of, Depends upon Mind of Observer.*—External Nature may be opposed to the intellectual world, as if the latter were not comprised within the limits of the former, or Nature may be opposed to art when the latter is defined as a manifestation of the intellectual power of man; but these contrasts, which we find reflected in the most cultivated languages, must not lead us to separate the sphere of Nature from that of mind, since such a separation would reduce the physical science of the world to a mere aggregation of empirical specialties. Science does not present itself to man until mind conquers matter in striving to subject the result of experimental investigation to rational combinations. Science is the labor of mind applied to Nature, but the external world has no real existence for us beyond the image reflected within ourselves through the medium of the senses. As intelligence and forms of speech, thought and its verbal symbols, are united by secret and indissoluble links, so does the external world blend almost unconsciously to ourselves with our ideas and feelings.—HUMBOLDT *Cosmos*, vol. i, int., p. 70. (H., 1897.)

2365. NATURE, HUMAN, KNOWLEDGE OF—*How Wise Men Learn.*—Confucius said (like Socrates): "I am not wise. But if any man, of humble condition, comes for information to me, who am empty, I make of him an object of research from every point, and exhaust him, while I enrich my own knowledge of human nature."—HAUG *Confucius der Weise (an Address* in *Virchow und Holtzendorf's Sammlung wissenschaftlicher Vorträge)*. (Translated for *Scientific Side-Lights.)*

2366. NATURE IGNORES MAN'S DIVIDING LINES—*Fauna of One Region Overlaps That of Another.*—In the study of the geographical distribution of terrestrial animals one of the great difficulties met with is the impossibility of defining exactly the limits of the regions into which we divide the surface of the earth. In a general way we recognize that there is an Australian region, an Ethiopian region, etc.; but, when we come to discuss the exact position of the frontier lines that separate these regions from their neighbors, we find all kinds of difficulties to overcome and inconsistencies to meet.

For the sake of convenience it is useful to adopt certain arbitrary limits for these regions, notwithstanding these difficulties and inconsistencies, but we must recognize the fact that Nature recognizes no such limits, that every region overlaps its neighbors to a greater or less extent, and that there are many debatable grounds in the world where the fauna characteristic of one region is mixed with that characteristic of another.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 45. (A., 1894.)

2367. NATURE IGNORES THE EXISTENCE OF MAN—*Drought and Volcano Regard Him Not.*—If the barren soil around Sydney had at once become fertile upon the landing of our first settlers; if, like the

happy isles whereof the poets have given such glowing descriptions, those sandy tracts had begun to yield spontaneously an annual supply of grain, we might then, indeed, have fancied alterations still more remarkable in the economy of Nature to have attended the first coming of our species into the planet. Or if, when a volcanic island like Ischia was, for the first time, brought under cultivation by the enterprise and industry of a Greek colony, the internal fire had become dormant, and the earthquake had remitted its destructive violence, there would then have been some ground for speculating on the debilitation of the subterranean forces, when the earth was first placed under the dominion of man. But after a long interval of rest the volcano bursts forth again with renewed energy, annihilates one-half of the inhabitants, and compels the remainder to emigrate. The course of Nature remains evidently unchanged; and, in like manner, we may suppose the general condition of the globe immediately before and after the period when our species first began to exist to have been the same, with the exception only of man's presence.—LYELL *Principles of Geology*, bk. i, ch. 9, p. 150. (A., 1854.)

2368. NATURE, INCITEMENTS TO STUDY OF—*Early Impressions Determine Life-work.*—In the simple consideration of the incitements to a scientific study of Nature, I would not omit calling attention to the fact that impressions arising from apparently accidental circumstances often —as is repeatedly confirmed by experience —exercise so powerful an effect on the youthful mind as to determine the whole direction of a man's career through life. The child's pleasure in the form of countries, and of seas and lakes, as delineated in maps; the desire to behold southern stars, invisible in our hemisphere; the representation of palms and cedars of Lebanon as depicted in our illustrated Bibles, may all implant in the mind the first impulse to travel into distant countries. If I might be permitted to instance my own experience, and recall to mind the source from whence sprang my early and fixed desire to visit the land of the tropics, I should name George Forster's "Delineations of the South Sea Islands," the pictures of Hodge, which represented the shores of the Ganges, and which I first saw at the house of Warren Hastings, in London, and a colossal dragontree in an old tower of the Botanical Garden at Berlin.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 20. (H., 1897.)

2369. NATURE, MUNIFICENCE OF—*Power of Sun's Whole Radiance—Would Melt in One Instant an Ice-bridge That Reached to the Moon.*—Let us suppose that we could sweep up from the earth all the ice and snow on its surface, and, gathering in the accumulations which lie on its arctic and antarctic poles, commence building with it a tower greater than that of Babel, fiftee miles in diameter, and so high as to exhaus our store. Imagine that it could be pre served untouched by the sun's rays, whil we built on with the accumulations of suc cessive winters, until it stretched out 240,00 miles into space, and formed an ice-bridg to the moon, and that then we concentrate on it the sun's whole radiation, neithe more nor less than that which goes on ever moment. In one second the whole woul be gone, melted, boiled, and dissipated i vapor. And this is the rate at which th solar heat is being (to human apprehension wasted!—LANGLEY *New Astronomy*, ch. 4 p. 96. (H. M. & Co., 1896.)

2370. NATURE NAMED "MATTER—*Mystery Not the End of Inquiry—Aristotle on "the Divine."*—What is generall called Nature Professor Tyndall names mat ter—a peculiar nomenclature, requiring ne definitions (as he avers), inviting misun derstanding, and leaving the questions w are concerned with just where they were For it is still to ask: Whence this ricl endowment of matter? Whence comes tha of which all we see and know is the out come? That to which potency may in th last resort be ascribed, Professor Tyndall suspending further judgment, calls myster —using the word in one of its senses, name ly, something hidden from us which we ar not to seek to know. But there are als mysteries proper to be inquired into and t be reasoned about; and altho it may no be given unto us to *know* the mystery o causation, there can hardly be a more legiti mate subject of philosophical inquiry. Mos scientific men have thought themselves in tellectually authorized to have an opinio about it. "For, by the primitive and ver ancient men, it has been handed down i the form of myths, and thus left to late generations, that the *Divine* it is which hold together all Nature"; and this tradition, o which Aristotle, both naturalist and philosopher, thus nobly speaks—continued through succeeding ages, and illuminated by the light which has come into the world—may still express the worthiest thoughts of the modern scientific investigator and reasoner.—ASA GRAY *Darwiniana*, art. 13, p. 389. (A., 1889.)

2371. NATURE OF FORCE UNKNOWN—*Gravitation Ascribed to a Supreme Will.*—We know nothing of the ultimate nature or of the ultimate seat of force. Science, in the modern doctrine of the conservation of energy, and the convertibility of forces, is already getting something like a firm hold of the idea that all kinds of force are but forms or manifestations of some one central force issuing from some one fountainhead of power. Sir John Herschel has not hesitated to say that "it is but reasonable to regard the force of gravitation as the direct or indirect result of a consciousness or a will existing

somewhere." ["Outlines of Astronomy," 5th ed., p. 291.] And even if we cannot certainly identify force in all its forms with the direct energies of One Omnipresent and All-pervading Will, it is at least in the highest degree unphilosophical to assume the contrary—to speak or to think as if the forces of Nature were either independent of or even separate from the Creator's power.—ARGYLL *Reign of Law*, ch. 2, p. 73. (Burt.)

2372. NATURE PAINTED IN SHADOW—*Earth an Inferno or a Slaughter-house.*—The final result [of the doctrine of the struggle for life, as commonly stated] is a picture of Nature wholly painted in shadow—a picture so dark as to be a challenge to its Maker, an unanswered problem to philosophy, an abiding offense to the moral nature of man. The world has been held up to us as one great battle-field heaped with the slain, an inferno of infinite suffering, a slaughter-house resounding with the cries of a ceaseless agony.—DRUMMOND *Ascent of Man*, int., p. 19. (J. P., 1900.)

2373. NATURE, SECRETS OF, TO WHOM REVEALED—*Scientist Must Become as a Little Child.*—In the law-book of research on which natural science is based we read the same command as in the Scriptures: "Verily I say unto you, except ye become as little children ye shall not enter into the kingdom of heaven." Accordingly, we see the investigator everywhere striving to turn back to the standpoint of a child that forgets all sorrow whenever something that moves is given him to look at; it matters little whether a tin-plate set to spin, or a pussy in her play. Only, of course, between the manner in which the scientist marvels at these phenomena and that of a child there lies the chasm that separates the moral value of a human being ripened by experience from the innocence of a child.—DU BOIS-REYMOND *Tierische Bewegung (a Lecture).* (Translated for *Scientific Side-Lights.*)

2374. NATURE SEEN AT WORK—*Formation of Peat within a Human Lifetime.*—George, first Earl of Cromarty, seems . . . to have been a man of an eminently active and inquiring mind. He found leisure, in the course of a very busy life, to write several historical dissertations of great research. . . . His life was extended to extreme old age; and as his literary ardor remained undiminished till the last, some of his writings were produced at a period when most other men are sunk in the incurious indifferency and languor of old age. And among these later productions are his remarks on peat. He relates that when a very young man he had marked, in passing on a journey through the central Highlands of Ross-shire, a wood of very ancient trees, doddered and moss-grown, and evidently passing into a state of death through the last stages of decay. He had been led by business into the same district many years after, when in middle life, and found that the wood had entirely disappeared, and that the heathy hollow which it had covered was now occupied by a green, stagnant morass, unvaried in its tame and level extent by either bush or tree. In his old age he again visited the locality, and saw the green surface roughened with dingy-colored hollows, and several Highlanders engaged in it in cutting peat in a stratum several feet in depth. What he had once seen an aged forest had now become an extensive peat-moss.—MILLER *The Old Red Sandstone*, ch. 10, p. 173. (G. & L., 1851.)

2375. NATURE STIRS VARIED HUMAN EMOTIONS—The contemplation of the individual characteristics of the landscape, and of the conformation of the land in any definite region of the earth, gives rise to a different source of enjoyment. . . . At one time the heart is stirred by a sense of the grandeur of the face of Nature, by the strife of the elements, or, as in Northern Asia, by the aspect of the dreary barrenness of the far-stretching steppes; at another time softer emotions are excited by the contemplation of rich harvests wrested by the hand of man from the wild fertility of Nature, or by the sight of human habitations raised beside some wild and foaming torrent.—HUMBOLDT *Cosmos*, vol. i, int., p. 25. (H., 1897.)

2376. NATURE, STUDY OF, INTERESTS CHILDREN—*General Phenomena of Life Readily Learned—Lessons in Insects, Plants, or Shells.*—From pupils of ten or twelve years of age who have been properly instructed in the elements of biology, one may obtain a surprising accuracy in the answers given to both written and oral questions. The chief idea, however, to be borne in mind in teaching pupils of this early age is that the instruction must be limited to broad and general details, and, save in very exceptional cases, must not include attempts at specializing the science. The general phenomena of plant and animal life; the broad relations of the organic and inorganic worlds, and the general details of the structure and life history of the more familiar groups of animals and plants, present subjects which may be made, with sufficient means of illustration, to convey a great amount of solid information to the youngest pupil who is able to think for himself or herself. For example, I do not see that an intelligent teacher, with a good set of diagrams and a few specimens, should have the slightest difficulty in interesting a very youthful auditory in the structure and metamorphosis of insects, and in the general course of insect life. He would find in the details furnished by the common observation of his pupils a ready assent to and illustration of most of the facts he would

set before them; and he would send them back with renewed interest from his classroom to study the caterpillars in the garden, or the development of the silkworm's eggs, which formerly had been kept as mere playthings. A lecture on "Shells and their Inmates" would in like manner be readily illustrated; and with the aid of a few microscopes and some stagnant water the wonder and interest of the pupils might be excited over the description of lesser worlds than ours.—ANDREW WILSON *Biology in Education*, p. 17. (Hum., 1888.)

2377. NATURE SURPASSES HUMAN ESTIMATE—*A Hundred Feet of Iron Rods to Sound a Glacier.*—When I first began my investigations upon the glaciers, now more than twenty-five years ago, scarcely any measurements of their size or their motion had been made. One of my principal objects, therefore, was to ascertain the thickness of the mass of ice, generally supposed to be from eighty to a hundred feet, and even less. The first year I took with me a hundred feet of iron rods (no easy matter, where it had to be transported to the upper part of a glacier on men's backs), thinking to bore the glacier through and through. As well might I have tried to sound the ocean with a ten-fathom line. The following year I took two hundred feet of rods with me, and again I was foiled. Eventually I succeeded in carrying up a thousand feet of line, and satisfied myself, after many attempts, that this was about the average thickness of the glacier of the Aar, on which I was working.—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 294. (H. M. & Co., 1896.)

2378. NATURE SURPASSES MAN—*Natural Surpasses Human Selection.*—As man can produce and certainly has produced a great result by his methodical and unconscious means of selection, what may not natural selection effect? Man can act only on external and visible characters; Nature, if I may be allowed to personify the natural preservation or survival of the fittest, cares nothing for appearances, except in so far as they are useful to any being. She can act on every internal organ, on every shade of constitutional difference, on the whole machinery of life. Man selects only for his own good; Nature only for that of the being which she tends. . . . Under Nature the slightest differences of structure or consititution may well turn the nicely balanced scale in the struggle for life, and so be preserved. How fleeting are the wishes and efforts of man! How short his time, and consequently how poor will be his results, compared with those accumulated by Nature during whole geological periods! Can we wonder, then, that Nature's productions should be far "truer" in character than man's productions; that they should be infinitely better adapted to the most complex conditions of life, and should plainly bear the stamp of far higher workmanship?—DARWIN *Origin of Species*, ch. 4, p. 76. (Burt.)

2379. NATURE'S BOATS HAVE WATER-TIGHT COMPARTMENTS—*Seeds That Bide Their Time.*—In the driftwood may be found dry fruits of the bladdernut, brown and light, an inch and a half in diameter. See how tough they are; they seem to be perfectly tight, and, even if one happens to have a hole punched in its side, there are probably two cells that are still tight, for there are three in all. Within are a few seeds, hard and smooth. Why are they so hard? Will it not be difficult for such seeds to get moist enough and soft enough to enable them to germinate? The hard coats enable the seeds to remain uninjured for a long time in the water, in case one or two cells of the papery pods are broken open; and after the tough pod has decayed and the seeds have sunken to the moist earth among the sticks and dead leaves, they can have all the time they need for the slow decay of their armor. Sooner or later a tiny plant is likely to appear and produce a beautiful bush. . . . But this is not all. Many of the dry nuts hang on all winter, or for a part of it, rattling in the wind, as tho loath to leave. Some of them are torn loose, and in winter there will be a better chance than at any other time for the wind to do the seeds a favor, especially when there is snow on the ground, for then they will bound along before the breeze till something interrupts them.—BEAL *Seed Dispersal*, ch. 4, p. 22. (G. & Co., 1898.)

2380. NATURE'S CARVING—*Rocks Cut and Polished by Glacier.*—This Grimsel is a weird region—a monument carved with hieroglyphics more ancient and more grand than those of Nineveh or the Nile. It is a world disinterred by the sun from a sepulcher of ice. All around are evidences of the existence and the might of the glaciers which once held possession of the place. All around the rocks are carved, and fluted, and polished, and scored. Here and there angular pieces of quartz, held fast by the ice, inserted their edges into the rocks and scratched them like diamonds, the scratches varying in depth and width according to the magnitude of the cutting stone. Larger masses, held similarly captive, scooped longitudinal depressions in the rocks over which they passed, while in many cases the polishing must have been effected by the ice itself. A raindrop will wear a stone away; much more would an ice surface, squeezed into perfect contact by enormous pressure, rub away the asperities of the rocks over which for ages it was forced to slide. The rocks thus polished by the ice itself are so exceedingly smooth and slippery that it is impossible to stand on them where their inclination is at all considerable.—TYNDALL *Hours of Exercise in the Alps*, ch. 7, p. 75. (A., 1898.)

2381. NATURE'S CONFORMITY TO LAW, THE FASCINATION OF—The greatest instance of what the human mind can effect by means of a well-recognized law of natural phenomena is that afforded by modern astronomy. The one simple law of gravitation regulates the motions of the heavenly bodies not only of our own planetary system, but also of the far more distant double stars, from which even the ray of light, the quickest of all messengers, needs years to reach our eye; and just on account of this simple conformity with law the motions of the bodies in question can be accurately predicted and determined both for the past and for future years and centuries to a fraction of a minute.

On this exact conformity with law depends also the certainty with which we know how to tame the impetuous force of steam and to make it the obedient servant of our wants. On this conformity depends, moreover, the intellectual fascination which chains the physicist to his subjects.—HELMHOLTZ *On the Conservation of Force, Popular Scientific Lectures*, p. 318. (Translated for *Scientific Side-Lights.)*

2382. NATURE'S FURNACES—*Crater of Volcano Filled with Boiling Lava.*—No one can look down on the mass of seething material in violent agitation within the fissures at the bottom of the crater of Stromboli, without being forcibly reminded of the appearances presented by liquids in a state of boiling or ebullition. The glowing material seems to be agitated by two kinds of movements, the one whirling or rotatory, the other vertical or up-and-down in its direction. The fluid mass in this way appears to be gradually impelled upwards till it approaches the lips of the aperture, when vast bubbles are formed upon its surface, and to the sudden bursting of these the phenomena of the eruption are due.—JUDD *Volcanoes*, ch. 2, p. 19. (A., 1899.)

2383. NATURE'S GREAT RESOLVENT—Except in very rare cases Nature never makes use of any other acid than carbonic acid to bring about decompositions, transformations, or new formations.—TIRKEL *Die Umwandlungsprocesse im Mineralreich*, p. 30. (Translated for *Scientific Side-Lights.)*

2384. NATURE'S MANY HUES FROM THREE PRIMARY COLORS—Young, Helmholtz, and Maxwell reduce all differences of hue to combinations in different proportions of three primary colors. It is demonstrable by experiment that from the red, green, and violet all the other colors of the spectrum may be obtained.—TYNDALL *Light*, lect. 1, p. 40. (A., 1898.)

2385. NATURE'S MASTERPIECES OF LIFE—*Inheritance from Ancient Ages.*—Above all other [forms], we should protect and hold sacred those types, Nature's masterpieces, which are first singled out for destruction on account of their size, or splendor, or rarity, and that false detestable glory which is accorded to their most successful slayers. In ancient times the spirit of life shone brightest in these; and when others that shared the earth with them were taken by death they were left, being more worthy of perpetuation. Like immortal flowers they have drifted down to us on the ocean of time, and their strangeness and beauty bring to our imaginations a dream and a picture of that unknown world, immeasurably far removed, where man was not: and when they perish, something of gladness goes out from Nature, and the sunshine loses something of its brightness.—HUDSON *Naturalist in La Plata*, ch. 1, p. 29. (C. & H., 1895.)

2386. NATURE'S NON-CONDUCTING MEDIUM—*Experiment with Molten Iron.*—Mr. Nasmyth, the inventor of the steam-hammer, has lately illustrated, by a very striking experiment, the non-conductibility of a thin layer of dry sand and clay. Into a caldron of iron one-fourth of an inch thick, lined with sand and clay five-eighths of an inch thick, he poured eight tons of melted iron at a white heat. After the fused metal had been twenty minutes in the caldron the palm of the hand could be applied to the outside without inconvenience, and after forty minutes there was not heat enough to singe writing-paper. This fact may help us to explain how strata in contact with dikes, or beds of fused matter, have sometimes escaped without perceptible alteration by heat.—LYELL *Geology*, ch. 25, p. 413. (A., 1854.)

2387. NATURE'S PARADOX—*Water an Unyielding Substance—Bacon First Proved It Incompressible—"The Florentine Experiment" a Later Copy.*—Water yields so freely to the hand that you might suppose it to be easily squeezed into a smaller space. That this is not the case was proved more than two hundred and sixty years ago by Lord Bacon. He filled a hollow globe of lead with the liquid, and, soldering up the aperture, tried to flatten the globe by the blows of a heavy hammer. He continued hammering "till the water, impatient of further pressure, exuded through the solid lead like a fine dew." Water was thus proved to offer an immense resistance to compression. Nearly fifty years afterwards, a similar experiment, with the same result, was made by the members of the Academy Del Cimento in Florence. They, however, used a globe of silver instead of a globe of lead. This experiment is everywhere known as "the Florentine experiment"; but Ellis and Spedding, the eminent biographers of Bacon, have clearly shown that it ought to be called "the Baconian experiment."—TYNDALL *New Fragments*, p. 343. (A., 1897.)

2388. NATURE'S PICTURE-BOOK—*Wonders of Geology.*—We may turn over these wonderful leaves [strata] one after

one, like the leaves of a herbarium, and find the pictorial records of a former creation in every page. Scallops, and gryphites, and ammonites, of almost every variety peculiar to the formation, and at least some eight or ten varieties of belemnite; twigs of wood, leaves of plants, cones of an extinct species of pine, bits of charcoal, and the scales of fishes; and, as if to render their pictorial appearance more striking, tho the leaves of this interesting volume are of a deep black, most of the impressions are of a chalky whiteness. I was lost in admiration and astonishment, and found my very imagination paralyzed by an assemblage of wonders that seemed to outrival, in the fantastic and the extravagant, even its wildest conceptions. I passed on from ledge to ledge, like the traveler of the tale through the city of statues.—MILLER *The Old Red Sandstone*, ch. 1, p. 10. (G. & L., 1851.)

2389. NATURE'S PREMIUM ON GOOD MOTHERS—*The Survival of the Fittest Forces Altruism upon the World.*—A mother who did not care for her children would have feeble and sickly children. Their children's children would be feeble and sickly children. And the day of reckoning would come when they would be driven off the field by a hardier, that is a better-mothered, race. Hence the premium of Nature upon better mothers. Hence the elimination of all the reproductive failures, of all the mothers who fell short of completing the process to the last detail. And hence, by the law of the survival of the fittest, altruism, which at this stage means good-motherism, is forced upon the world.—DRUMMOND *Ascent of Man*, ch. 7, p. 265. (J. P., 1900.)

2390. NATURE'S PURIFIER—*Sand the Great Filter.*—So convinced was Koch of the efficiency of sand-filtration as protection against disease-producing germs that he advocated an adaptation of this plan in places where it was found that a well yielded infected water. Such pollution in a well may be due to various causes; surface-polluted water oozing into the well is probably the commonest, but decaying animal or vegetable matter might also raise the number of micro-organisms present almost indefinitely. Koch's proposal for such a polluted well was to fill it up with gravel to its highest water-level, and above that, up to the surface of the ground, with fine sand. Before the well is filled up in this manner it must, of course, be fitted with a pipe passing to the bottom and connected with a pump. This simple procedure of filling up a well with gravel and sand interposes an effectual filter-bed between the subsoil water and any foul surface water percolating downwards. Such an arrangement yields as good, if not better, results than an ordinary filter-bed, on account of there being practically no disturbance of the bed nor injury done to it by frost.—NEWMAN *Bacteria*, ch. 2, p. 77. (G. P. P., 1899.)

2391. NATURE'S STEAM-JETS—*Vast Masses of Rock Ejected from Volcano.*—A volcano is essentially a steam-jet, and the steam almost certainly is derived from water buried in the rocks at the time of their formation. The quantity of matter extruded by a volcano is very great. We get an inadequate sense of its mass from the cones which are accumulated about the point of ejection. Thus in the case of Etna, a volcano, vast tho it is, of the second order of magnitude in terrestrial cones, we find in and around the elevation a mass of ejected rocky material which amounts in volume to somewhere near one thousand cubic miles; yet this prodigious mass of matter is only a small part of that which has been ejected from the vent.—SHALER *Nature and Man in America*, ch. 2, p. 62. (S., 1899.)

2392. NAVIGATION, ANCIENT—*The Merchant Princes of Other Days—Phenicians and Sidonians.*—The [Phenicians] . . . widened the domain of knowledge in several directions by independent inventions of their own. A state of industrial prosperity, based on an extensive maritime commerce, and on the enterprise manifested at Sidon in the manufacture of white and colored glasswares, tissues, and purple dyes, necessarily led to advancement in mathematical and chemical knowledge, and more particularly in the technical arts. "The Sidonians," writes Strabo, "are described as industrious inquirers in astronomy, as well as in the science of numbers, to which they have been led by their skill in arithmetical calculation, and in navigating their vessels by night, both of which are indispensable to commerce and maritime intercourse."—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 129. (H., 1897.)

2393. NAVIGATION BY SPIDERS—*The Raft of the Hunting-spider.*—The following is quoted from Büchner:

"Less idyllic than the water-spider is our native hunting-spider, *Dolomedes fimbriata*, which belongs to those species which spin no web, but hunt their victims like animals of prey. As the *Argyroneta* is the discoverer of the diving-bell, so may this be regarded as the discoverer or first builder of a floating raft. It is not content with hunting insects on land, but follows them on the water, on the surface of which it runs about with ease. It, however, needs a place to rest on, and makes it by rolling together dry leaves and such like bodies, binding them into a firm whole with its silken threads. On this raftlike vessel it floats at the mercy of wind and waves; and if an unlucky water-insect comes for an instant to the surface of the water to breathe, the spider darts at it with lightning speed, and carries it back to its raft to devour at its ease.—ROMANES *Animal Intelligence*, ch. 6, p. 213. (A., 1899.)

2394. NAVIGATION GUIDED BY THE STARS—*Mariners of Tyre and Sidon*—

The Cynosure.—At the epoch when the maritime power of the Phenicians was at its apogee, about 3,000 years ago, or twelve centuries before our era, it was the star β of the Little Bear . . . which was the nearest bright star to the pole, and the skilful navigators of Tyre and Sidon (O purpled kings of former times! what remains of your pride?) had recognized the seven stars of the Little Bear, which they named the Tail of the Dog, "Cynosura"; they guided themselves by the pivot of the diurnal motion, and during several centuries they surpassed in precision all the mariners of the Mediterranean. The dog had given place to a bear, doubtless on account of the resemblance of the configuration of these seven stars to the seven of the Great Bear, but the tail remains long and curled up, in spite of the nature of the new animal.

Thus the stars of the north at first served as points of reference for the first men who dared to venture on the seas. But they served at the same time as guides on the mainland for the nomadic tribes who carried their tents from country to country. In the midst of savage nature, the first warriors themselves had nothing but the Little Bear to guide their steps.—FLAMMARION *Popular Astronomy,* bk. vi, ch. 1, p. 556. (A.)

2395. NAVY, BRITISH, STOPPAGE OF GROG IN—*Reduction of Crimes of Violence—Dangers of Incipient Intoxication.*—It would seem that in whatever way the exertion of volitional power is related to the condition of the brain, this exertion is interfered with by the use of intoxicating agents, before there is any serious perversion of the automatic [muscular] activity. . . . It is in this primary stage of alcoholic excitement that a large number of "crimes of violence," as well as of minor offenses, are committed, as is shown by the remarkable reduction in these which took place in the navy immediately that the "evening grog" was stopped. The following very characteristic instance of this kind was related to the Admiralty Committee on whose recommendation this change was made:

"I had a marine," said Captain Drew, "who was constantly complained against for quarreling and fighting and disobedience to the orders of his sergeant. At length I began with flogging him, and told him that I would increase his punishment every time that I had a complaint against him. This I had to do twice; and as the man was constantly excited it appeared to me that the man's reason must be affected. I therefore applied to the surgeon and asked him to examine the man to see whether he was not a fit subject for invaliding, but the surgeon reported that he was as fine and healthy a young man as there was in the ship. I then did not think myself justified in flogging him again, but took upon myself to do an illegal act with a good intention, and when we came into harbor (in the West Indies) I hired a cell in the gaol and kept him there three days upon bread and water. When the man came out of gaol I told him that whenever I had a complaint against him, as sure as we came into harbor I would send him to gaol; but that if he would choose to alter his conduct I would start afresh with him and forget everything that had happened. He said that he was very much obliged to me, and he came to me the next day and asked me if I would stop his allowance of grog and let him be paid for it. I did so, and never had another complaint against the man while I was in the ship."—CARPENTER *Mental Physiology,* ch. 17, p. 649. (A., 1900.)

2396. NEARNESS IN TIME ASCRIBED TO GREAT PUBLIC EVENTS—*Vividness Suggests Proximity.*—The most striking examples of the illusory effect of mere vividness, involving a complete detachment of the event from the prominent landmarks of the past, are afforded by public events which lie outside the narrower circle of our personal life, and which do not in the natural course of things become linked to any definitely localized points in the field of memory. These events may be very stirring and engrossing for the time, but in many cases they pass out of the mind just as suddenly as they entered it. We have no occasion to revert to them, and if by chance we are afterwards reminded of them they are pretty certain to look too near, just because the fact of their having greatly interested us has served to render their images particularly vivid.—SULLY *Illusions,* ch. 10, p. 258. (A., 1897.)

2397. NEBULÆ NOT WHOLLY COMPOSED OF STARS—*Gaseous Constituents—Perhaps Systems in Process of Formation.*—In many nebulæ small stars can be seen. . . . More stars are continually being discovered in them, the better are the telescopes used in their analysis. Thus, before the discovery of spectrum analysis, Sir W. Herschel's former view might be regarded as the most probable, that that which we see to be nebulæ are only heaps of very fine stars, of other "Milky Ways." Now, however, spectrum analysis has shown a gas spectrum in many nebulæ which contain stars.—HELMHOLTZ *Popular Lectures,* lect. 4, p. 187. (L. G. & Co., 1898.)

2398. NECESSITY OF CONFLICT AND WAR—*Combativeness Inherent in Man.*—In many respects man is the most ruthlessly ferocious of beasts. As with all gregarious animals, "two souls," as Faust says, "dwell within his breast," the one of sociability and helpfulness, the other of jealousy and antagonism to his mates. Tho in a general way he cannot live without them, yet, as regards certain individuals, it often falls out that he cannot live with them either. Constrained to be a member of a tribe, he still has a right to decide, as far as in him lies, of which other members the

tribe shall consist. Killing off a few obnoxious ones may often better the chances of those that remain. And killing off a neighboring tribe from whom no good thing comes, but only competition, may materially better the lot of the whole tribe. Hence the gory cradle, the *bellum omnium contra omnes*, in which our race was reared; hence the fickleness of human ties, the ease with which the foe of yesterday becomes the ally of to-day, the friend of to-day the enemy of to-morrow; hence the fact that we, the lineal representatives of the successful enactors of one scene of slaughter after another, must, whatever more pacific virtues we may also possess, still carry about with us, ready at any moment to burst into flame, the smoldering and sinister traits of character by means of which they lived through so many massacres, harming others, but themselves unharmed.—JAMES *Psychology*, vol. ii, ch. 24, p. 409. (H. H. & Co., 1899.)

2399. NECESSITY OF PAIN—*Its Chief Use Not for the Individual, but for the Race.*—We must, therefore, accept pain as a fact existing by a deep necessity, having its root in the essential order of the world. If we are to understand it, we must learn to look on it with different eyes. And does not a different thought suggest itself even while we recognize that the others fail? For if the reason and the end of pain lie beyond the results that have been mentioned, then they lie beyond the individual. Pain, if it exist for any purpose, and have any end or use—and of this what sufferer can endure to doubt?—must have some purpose which extends beyond the interest of the person who is called upon to bear it. . . .

These uses of pain, which concern the one who suffers only [as leading to avoidance of danger, etc.], must fail and be found insufficient. . . . But when we extend our thought, and recognize not only that there are, in pain, ends unseen by us, but that these ends may not be confined within the circle of our own interests, surely a light begins to glimmer through the darkness. While we look only at that which directly concerns the individual who suffers, no real explanation of suffering, no satisfaction that truly satisfies, can be found. But if we may look beyond and see in our own sufferings, and in the sufferings of all, something in which mankind also has a stake, then they are brought into a region in which the heart can deal with them and find them good. And if the heart, the reason also. For here it is the soul that is the judge; and if the heart is satisfied, the reason also is content.—HINTON *The Mystery of Pain*, p. 19. (Hum., 1893.)

2400. NEEDLE, MAGNETIC, ANCIENT KNOWLEDGE OF—*Early Chinese Record of "Needle Pointing South"—Polarity a Puzzle.*—No definite statement, however, is found until the end of the eleventh century is reached, and then in a work entitled "Mung-Khi-pithan" we meet the following extraordinary passage:

"The soothsayers rub a needle with the magnet stone so that it may mark the south; however, it declines constantly a little to the east. It does not indicate the south exactly. When this needle floats on the water it is much agitated. If the finger-nails touch the upper edge of the basin in which it floats they agitate it strongly, only it continues to slide and falls easily. It is better, in order to show its virtues in the best way, to suspend it as follows: Take a single filament from a piece of new cotton and attach it exactly to the middle of the needle by a bit of wax as large as a mustard-seed. Hang it up in a place where there is no wind. Then the needle constantly shows the south; but among such needles there are some which, being rubbed, indicate the north. Our soothsayers have some which show south and some which show north. Of this property of the magnet to indicate the south, like that of the cypress to show the west, no one can tell the origin."—BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 75. (J. W., 1898.)

2401. ——— ——— *Occident Indebted to Orient.*—While the gradually developed knowledge of relations in space incited men to think of shorter sea routes, the means for perfecting practical navigation were likewise gradually increased by the application of mathematics and astronomy, the invention of new instruments of measurement, and by a more skilful employment of magnetic forces. It is extremely probable that Europe owes the knowledge of the northern and southern directing powers of the magnetic needle—the use of the mariner's compass—to the Arabs, and that these people were in turn indebted for it to the Chinese. . . . In the third century of our era, under the dynasty of Han, there is a description given in Hiutschin's dictionary Schuewen of the manner in which the property of pointing with one end toward the south may be imparted to an iron rod by a series of methodical blows. Owing to the ordinary southern direction of navigation at that period, the south pointing of the magnet is always the one especially mentioned. A century later, under the dynasty of Tsin, Chinese ships employed the magnet to guide their course safely across the open sea, and it was by means of these vessels that the knowledge of the compass was carried to India, and from thence to the eastern coasts of Africa.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 253. (H., 1897.)

2402. NEGATION OF FIXED MODES GIVES MAN PREEMINENCE—*New Principles for New Cases.*—In them [the lower animals] fixed habit is the essential and characteristic law of nervous action. The brain grows to the exact modes in which it has been exercised, and the inheritance of these modes—then called instincts—would

have in it nothing surprising. But in man the negation of all fixed modes is the essential characteristic. He owes his whole preeminence as a reasoner, his whole human quality of intellect, we may say, to the facility with which a given mode of thought in him may suddenly be broken up into elements which recombine anew. Only at the price of inheriting no settled instinctive tendencies is he able to settle every novel case by the fresh discovery by his reason of novel principles.—JAMES *Psychology*, vol. ii, ch. 22, p. 368. (H. H. & Co., 1899.)

2403. NEGLECT, DETERIORATION THE PENALTY OF—*Effort Needed for Excellence (Heb. ii, 3).*—If we neglect a garden plant, then a natural principle of deterioration comes in and changes it into a worse plant. And if we neglect a bird, by the same imperious law it will be gradually changed into an uglier bird. Or if we neglect almost any of the domestic animals, they will rapidly revert to wild and worthless forms again.

Now the same thing exactly would happen in the case of you or me. Why should man be an exception to any of the laws of Nature? Nature knows him simply as an animal — subkingdom *Vertebrata*, class *Mammalia*, order *Bimana*. And the law of reversion to type runs through all creation If a man neglect himself for a few years he will change into a worse man and a lower man. If it is his body that he neglects, he will deteriorate into a wild and bestial savage, like the dehumanized men who are discovered sometimes upon desert islands. If it is his mind it will degenerate into imbecility and madness—solitary confinement has the power to unmake men's minds and leave them idiots. If he neglect his conscience, it will run off into lawlessness and vice. Or, lastly, if it is his soul, it must inevitably atrophy, drop off in ruin and decay.—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 88. (H. Al.)

2404. NEGLECT OF SANITATION INVITES ZYMOTIC DISEASE—*Oppression Opens the Way for Pestilence — Human Brotherhood May Involve the Most Discreet with the Most Degraded.*—We learn from this marvelous discovery [of the destruction of disease-germs by the leucocytes or white blood-corpuscles] that so long as we live simply and naturally, and obey the well-known laws of sanitation, so as to secure a healthy condition of the body, the more dreaded zymotic diseases will be powerless against us. But if we neglect these laws of health, or allow of conditions which compel large bodies of our fellow men to neglect them, these disease-germs will be present in such quantities in the air and the water around us that even those who personally live comparatively wholesome lives will not always escape them.—WALLACE *The Wonderful Century*, ch. 14, p. 146. (D. M. & Co., 1899.)

2405. NEIGHBOR, ANCIENT IDEA OF—*Moral Obligation Limited to Tribe.*—It must be clearly understood also that the Old-World rules of moral conduct were not the same towards all men. A man knew his duty to his neighbor, but all men were not his neighbors. This is very clearly seen in the history of men's ideas of manslaughter and theft. . . . The old state of things is well illustrated in the Latin word *hostis*, which, meaning originally "stranger," passed quite naturally into the sense of "enemy." Not only is slaying an enemy in open war looked on as righteous, but ancient law goes on the doctrine that slaying one's own tribesman and slaying a foreigner are crimes of quite different order, while killing a slave is but a destruction of property. Nor even now does the colonist practically admit that killing a brown or black man is an act of quite the same nature as killing a white countryman. Yet the idea of the sacredness of human life is ever spreading more widely in the world, as a principle applying to mankind at large.

The history of the notion of theft and plunder follows partly the same lines. In the lower civilization the law, "Thou shalt not steal," is not unknown, but it applies to tribesmen and friends, not to strangers and enemies.—TYLOR *Anthropology*, ch. 16, p. 411. (A., 1899.)

2406. NERVE-FORCE CAPABLE OF EXHAUSTION—*Sensations More Vivid after Remission—Maximum of Power Follows Repose.*—The nerve-pores and corpuscles, on being stimulated, undergo a process of change, whereby their power is gradually exhausted, in consequence of which they need remission and repose. Hence, the first moments of a stimulus are always the freshest, and give birth to the most vivid degrees of consciousness. This is the condition more especially requisite for maintaining a state of pleasurable sensibility. The nervous system should be duly refreshed or invigorated by nourishment and repose, and never pushed in any part to the extreme limits of exhaustion. The same condition applies to our power of active energy in every department, whether intellectual, voluntary, or emotional. Power is at the maximum, under a fresh start of renovated nerves, and fails as we approach the point of exhaustion. There are certain exceptional manifestations, as in the common experience of "growing warm" to one's work; the maximum of energy usually shows itself some time after commencing, an effect due entirely to the increased supply of blood following on a certain amount of exercise.—BAIN *Mind and Body*, ch. 4, p. 12. (Hum., 1880.)

2407. NERVES COMMUNICATE THROUGH CENTERS—*Illustration of Mail Sent through Distributing Office.*—The plan of communicating from one part of the body to another—as from the skin of the hand

to the muscles of the arm—is not by a direct route from the one spot to the other, but by a nervous center. Every nerve-fiber rising from the surface of the body, or from the eye or the ear, goes first of all to the spinal cord or to some part of the brain; and any influence exerted on the movements by stimulating these fibers passes out from some nervous center. As in the circulation of letters by post, there is no direct comunication between one street and another, but every letter passes first to the central office, so the transmission of influence from one member of the body to another is exclusively through a center, or (with a few exceptions) through some part of the nervous substance contained in the head and backbone. Every communication is centralized, and in consequence there is not only great economy of the conducting machinery, but also an avoidance of conflicting messages.—Bain *Mind and Body*, ch. 3, p. 8. (Hum., 1880.)

2408. NERVES, SPECIFIC ACTION OF—*Senses Never Confused—Eye Tells Only of Light, Ear of Sound.*—Every nerve of sense has a peculiar kind of sensation. We know that each nerve can be rendered active by a vast number of exciting agents, and that the same agent may affect different organs of sense; but no matter how it may be brought about, we never receive from nerves of sight any other sensation than that of light, nor from the nerves of the ear any other sensation than that of sound. In short, we derive from each individual nerve of sense that sensation only that corresponds to its specific action. The most marked differences in the qualities of sensation, that is to say, those between sensations from different senses, are consequently in no way dependent on the nature of the exciting agent, but only on the nerve apparatus that is operated upon.—Helmholtz *Aim and Progress of Physical Science (Popular Lectures on Scientific Subjects*, p. 391). (Translated for *Scientific Side-Lights.)*

2409. NERVES THE INTERPRETERS OF THE WORLD TO THE MIND—Between the mind of man and the outer world are interposed the nerves of the human body, which translate, or enable the mind to translate, the impressions of that world into facts of consciousness and thought.—Tyndall *Fragments of Science*, ch. 2, p. 28. (A., 1897.)

2410. NESTLINGS NOT TIMID IF GENTLY APPROACHED—*No Instinctive Fear of Man.*—To return to what may be seen in nestling birds. When very young, and before their education has well begun, if quietly approached and touched, they open their bills and take food as readily from a man as from the parent bird. But if while being thus fed the parent returns and emits the warning note they instantly cease their hunger cries, close their gaping mouths, and crouch down frightened in the nest.—Hudson *Naturalist in La Plata*, ch. 5, p. 89. (C. & H., 1895.)

2411. NESTS REBUILT ON SAME SITES—*Migratory Birds Return to Early Homes.*—For many years in succession a pair of blue titmice built their nest in an earthenware bottle placed in the branches of a tree in a garden at Oxbridge, near Stockton-on-Tees, and even where the surface of the country has undergone a complete change some species will continue breeding on the beloved spot. In America orioles and vireos appear to return to the same tree, or even to affix their nest to the same branch, for many successive years; and in like manner Allen has noticed how the wren, the pewee, and the robin repeatedly occupy the same nesting sites.—Brown *Nature-Studies*, p. 16. (Hum., 1888.)

2412. NET, THE, COEVAL WITH HISTORY—*Egyptian Monuments Show Its Skilful Use.*—The net is one of the things known to almost all men so far as history can tell. The native Australians net game like ancient Assyrians or English poachers, and are not less skilled in netting wild fowl. To see this art at its height we may look at the pictures of fowling-scenes on the monuments of ancient Egypt, which show the great clap-nets taking geese by scores; even the souls of the dead are depicted rejoicing in this favorite sport in the world beyond the tomb.—Tylor *Anthropology*, ch. 9, p. 212. (A., 1899.)

2413. NEWS "AHEAD OF TIME"—*Electricity Outtravels the Sun.*—We are now able to receive accounts of great events almost while they are happening on the other side of the globe; and, owing to difference of longitude, we sometimes can hear of an event apparently before it has happened. If some great official were to die at Calcutta at sunset, we should receive the news soon after noon on the same day.—Wallace *The Wonderful Century*, ch. 3, p. 21. (D. M. & Co., 1899.)

2414. NEWS BY TELEPHONE—*Printing of Extras Dispensed with.*—The telephone is actually in operation at Budapest in the form of a telephonic newspaper. At certain fixed hours throughout the day a good reader is employed to send definite classes of news along the wires which are laid to subscribers' houses and offices, so that each person is able to hear the particular items he desires, without the delay of its being printed and circulated in successive editions of a newspaper. It is stated that the news is supplied to subscribers in this way at little more than the cost of a daily newspaper, and that it is a complete success.—Wallace *The Wonderful Century*, ch. 3, p. 23. (D. M. & Co., 1899.)

2415. NEWTON SECURES A FILM THAT IS VARIABLE AND MEASURABLE

—*Newton's Rings—Illustrate Interference of Light-waves.*—Newton . . . determined by accurate measurements the relation of the thickness of the film to the color of displays. [See COLORS OF THIN PLATES; PLATES.] In doing this his first care was to obtain a film of variable and calculable depth. On a plano-convex glass lens . . . of very feeble curvature he laid a plate of glass . . . with a plane surface, thus obtaining a film of air of gradually increasing depth from the point of contact . . . outwards. On looking at the film in monochromatic light he saw, with the delight attendant on fulfilled prevision, surrounding the place of contact a series of bright rings separated from each other by dark ones and becoming more closely packed together as the distance from the point of contact augmented. . . . When he employed red light, his rings had certain diameters; when he employed blue light, the diameters were less. In general terms, the more refrangible the light the smaller were the rings. Causing his glasses to pass through the spectrum from red to blue, the rings gradually contracted; when the passage was from blue to red, the rings expanded. This is a beautiful experiment, and appears to have given Newton the most lively satisfaction. When white light fell upon the glasses, inasmuch as the colors were not superposed, a series of *iris-colored circles* was obtained. . . . In monochromatic light the rings run closer and closer together as they recede from the center. This is due to the fact that at a distance the film of air thickens more rapidly than near the center. When white light is employed this closing up of the rings causes the various colors to be superposed, so that after a certain thickness they are blended together to white light, the rings then ceasing altogether.—TYNDALL *Lectures on Light*, lect. 2, p. 72. (A., 1898.)

2416. NICHE OF SCIENCE UNFILLED—*Why Not a Shrine of Deity (Ps. xc, 2).*—" Does the vital," he [Professor Knight] asks, " proceed by a still remoter development from the non-vital? Or was it created by a fiat of volition? Or "—and here he emphasizes his question—" *has it always existed in some form or other as an eternal constituent of the universe?* I do not see," he replies, " how we can escape from the last alternative." With the whole force of my conviction I say, Nor do I, tho our modes of regarding the " eternal constituent " may not be the same.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 376. (A., 1900.)

2417. NIGHT, ADAPTATION TO—*Colors of Nocturnal Animals.*—Nocturnal animals supply another illustration of the same rule [of protective coloration] in the dusky colors of mice, rats, bats, and moles, and in the soft-mottled plumage of owls and goat-suckers which, while almost equally inconspicuous in the twilight, are such as to favor their concealment in the daytime.—WALLACE *Darwinism*, ch. 8, p. 131. (Hum.)

2418. NIGHT AND DAY, MYTHS WOVEN AROUND—*Story of Little Red Riding-hood an Ancient Relic.*—Of all the nature-myths of the world few are so widely spread as those on this theme of night and day, where with mythic truth the devoured victims were afterwards disgorged or set free. The Zulu story-tellers describe the maw of the monster as a country where there are hills and houses and cattle and people living, and, when the monster is cut open, all the creatures come out from the darkness; with a neat touch of nature, which shows that the story-teller is thinking of the dawn, the cock comes out first, crying " *kukuluku!* I see the world!" Our English version of the old myth is the nursery tale of Little Red Riding-hood, but it is spoilt by leaving out the proper end (which German nurses have kept up with better memory), that when the hunter ripped up the sleeping wolf out came the little damsel in her red satin cloak, safe and sound.—TYLOR *Anthropology*, ch. 15, p. 392. (A., 1899.)

2419. NIGHT A TIME OF ANXIETY TO PRIMEVAL MAN—*What if Day Should Return No More?—Joyous Welcome to the Rising Sun.*—The ancient poems of India have even preserved for us the last echoes of the fears of primeval man at the approach of night. The sun, the good sun, has completely disappeared in the west: is it certain that he will return to-morrow morning in the east? If he should return no more! no more light, no more heat; the frozen night, gloomy night, covers the world! How shall we recover the lost fire? How replace the beneficent sun and his celestial light? The stars from the height of the heavens shed their melancholy light; the moon pours out in the vacuities of the atmosphere that rosy, silvery light which diffuses such a charm upon the sleep of Nature; but this is not the sun, this is not the day. . . . Ah, see the dawn, which brightens slowly! Behold the light, behold the day! Sun! King of the heavens, be blessed! Oh! never forget to return!—FLAMMARION *Popular Astronomy*, bk. i, ch. 2, p. 13. (A.)

2420. NIGHT IN TROPICAL FOREST—*Discordant Cries—Wide-spread Conflict among Animals.*—After eleven o'clock, such a noise began in the contiguous forest that for the remainder of the night all sleep was impossible. The wild cries of animals rung through the woods. Among the many voices which resounded together, the Indians could only recognize those which, after short pauses, were heard singly. There was the monotonous, plaintive cry of the *Aluates* (howling monkeys), the whining, flutelike notes of the small sapajous, the grunting murmur of the striped nocturnal ape

(Nyctipithecus trivirgatus, . . .), the fitful roar of the great tiger (the cougar or maneless American lion), the peccary, the sloth, and a host of parrots, parraquas *(Ortalides)*, and other pheasant-like birds. Whenever the tigers approached the edge of the forest, our dog, who before had barked incessantly, came howling to seek protection under the hammocks. Sometimes the cry of the tiger resounded from the branches of a tree, and was then always accompanied by the plaintive piping tones of the apes, who were endeavoring to escape from the unwonted pursuit.

If one asks the Indians why such a continuous noise is heard on certain nights, they answer, with a smile, that "the animals are rejoicing in the beautiful moonlight and celebrating the return of the full moon." To me the scene appeared rather to be owing to an accidental, long-continued, and gradually increasing conflict among the animals. Thus, for instance, the jaguar will pursue the peccaries and the tapirs, which, densely crowded together, burst through the barrier of treelike shrubs which opposes their flight. Terrified at the confusion, the monkeys on the tops of the trees join their cries with those of the larger animals. This arouses the tribes of birds who build their nests in communities, and suddenly the whole animal world is in a state of commotion. Further experience taught us that it was by no means always the festival of moonlight that disturbed the stillness of the forest; for we observed that the voices were loudest during violent storms of rain, or when the thunder echoed and the lightning flashed through the depths of the woods.—HUMBOLDT *Views of Nature*, p. 199. (Bell, 1896.)

2421. NIGHT, NEED OF — *Celestial Splendors Revealed Only in Darkness—Astronomers on Worlds Lighted by Double Suns Journeying Afar to Obtain More Night—The Starry Heavens Deemed More Magnificent if Seldom Seen.*—Very singular also must be the aspect of the different planets which are variously illuminated by the orange and blue suns. Instead of shining as the planets of the solar system shine, with a nearly constant color—their own inherent color—the planets of a double-sun system must vary in aspect according to their positions with respect to the two suns which illuminate them.

There is but one circumstance in which the celestial scenery presented to ourselves surpasses that which must be exhibited to the inhabitants of such a world as we have been considering. The glories of the star-depths are seldom seen from such a world; night is the exception, and often for many weeks in succession there can be no real night, but an alternation of colored days scarcely separated by brief periods of colored twilight when the orange and blue suns are but slightly below opposite horizons. It may be that on this very account night, being rare, is more valued, and the significance of the night-sky more imposing than with ourselves. But it is a strange thought that the astronomers of those distant worlds—for such worlds we must believe there are—may, in their zeal for science, undertake long journeys to obtain more night during which they may study the wonders of the starlit heavens.—PROCTOR *Expanse of Heaven*, p. 233. (L. G. & Co., 1897.)

2422. NIGHT VOCAL WITH BIRDS OF PASSAGE—*Aerial Armies Crossing Land and Sea—Nocturnal Migration of Birds.*—But marked tho the migratory season is in England, we see less of it than do our Continental neighbors, especially those who inhabit countries on the line of the great spring and autumn flights to and from the north of Europe. Morning and evening, and, indeed, all day long, the Heligolander may watch from his red rock in the North Sea the wild ducks winging their way in long "badelynges," led by an elderly drake performing the part of a personal conductor, and quaking with joy at the sight of the river-mouth which they had in memory ever since they left the Lapland lakes or the Siberian tundra. Every night—unless the sky is clear and the moon enables the migrants to continue their flight without trepidation—there is a Babel-like clamor overhead, and the lighthouse lantern is surrounded by myriads of larks, snipes, and plover, which have beat against it on their dreary night-journey from the north, or by the mysterious-mannered knots returning from their philanderings in some nameless land around the pole. In one night sometimes as many as 15,000 larks have been caught, and tho the resident birds of Heligoland do not exceed a dozen species, it is, perhaps, no exaggeration to say that the visitors exceed those of the greatest country in Europe.—BROWN *Nature-Studies*, p. 13. (Hum., 1888.)

2423. NIGHTMARE OF ANTHROPOMORPHISM—*Conception of Supreme Intelligence Treated as an Absurdity.*—Another nightmare meets us here—another suggestion of hopeless doubt respecting the very possibility of knowledge touching questions such as these. . . . The suggestion, in short, is not merely that the answer to these questions is inaccessible, but that there is no answer at all. The objection is a fundamental one, and is summed up in the epithet applied to all such inquiries—that they are "anthropomorphic." They assume authorship in a personal sense, which is a purely human idea; they assume causation, which is another human idea, and they assume the use of means for the attainment of ends, which also is purely human. It is considered by some persons as a thing in itself absurd that we should thus shape our conceptions of the ruling Power in Nature, or of a Divine Being, upon the conscious knowledge we have of our

own nature and attributes. Anthropomorphism is the phrase employed to condemn this method of conception—an opprobrious epithet, as it were, which is attached to every endeavor to bring the higher attributes of the human mind into any recognizable relation with the supreme agencies in Nature.—ARGYLL *Unity of Nature*, ch. 5, p. 99. (Burt.)

2424. NITROGEN, LOSS OF, AS AFFECTED BY ALCOHOL — *Recent Experiments in Germany.*—Miura justly drew the conclusion that in his experiments alcohol had not only proved itself as not albumin-saving, but as a protoplasm poison.

Finally, we have also the most recent experiments by Schmidt and Schöneseiffen, performed with the greatest precautions under Rosemann at Greifswald. Schmidt added alcohol to the food by which he had obtained his nitrogenous equilibrium in such quantity that if the number of calories had been furnished by carbohydrates they certainly would have produced a considerable storing up of nitrogen, whereas the addition of alcohol produced a considerable loss of body-albumin. [Schmidt, "Inaugural Dissertation," Greifswald, 1898.]

Schöneseiffen adopted another method in his experiments. At first an insufficient amount of food was given, so that daily there was a slight loss of nitrogen. After this, alcohol was given in such a quantity that the number of calories were not only compensated, but supplied in more than double the number required. This would have led to a storing up of nitrogen if the calories had been supplied by carbohydrates. But the experiment showed that not even the loss of nitrogen was stopped by alcohol. Hence, here again, alcohol has not manifested any albumin-saving properties. [Schöneseiffen, *idem*, 1899.]

If we sum up the results of these experiments we certainly must agree with Rosemann, when, in direct contradiction to the previous statement by Binz, he regards as demonstrated that alcohol has not the power of preventing the waste of albumin in the body. [Aside from these valuable investigations, Rosemann has rendered important service by an elaborate review of some recent experiments upon the albumin-saving action of alcohol. . . . In this connection we would refer the reader to his two articles in Pflüger's "Archiv," vols. lxxvii and lxxix.]—KASSOWITZ *Is Alcohol a Food or a Poison? (a Paper)*, p. 6. (Translation by Mrs. J. H. W. STUCKENBERG.)

2425. NITROGEN OF ATMOSPHERE UNLIMITED, BUT UNASSIMILABLE—*Must Be Fixed in Soil for Plants.*—The store of nitrogen in the atmosphere is practically unlimited, but it is fixed and rendered assimilable only by cosmic processes of extreme slowness. . . . It is upon these processes, plus a return to the soil of sewage, that we must depend in the future for storing nitrogen as nitrates [in which condition only it can be of service to plants].—NEWMAN *Bacteria*, ch. 5, p. 161. (G. P. P., 1899.)

2426. NITROGEN SUPPLIED TO PLANTS BY BACTERIA—*Nitrification and Denitrification.*—The chief results of decomposition and denitrification are as follows: Free nitrogen, carbonic-acid gas and water, ammonia bodies, and sometimes nitrites. The nitrogen passes into the atmosphere and is "lost"; the carbonic acid and water return to Nature and are at once used by vegetation. The ammonia and nitrites await further changes. These further changes become necessary on account of the fact, already discussed, that plants require their nitrogen to be in the form of nitrates in order to use it. Nitrates obviously contain a considerable amount of oxygen, but ammonia contains no oxygen, and nitrites very much less than nitrates. Hence a process of oxidation is required to change the ammonia into nitrites, and the nitrites into nitrates. This oxidation is performed by the nitrifying micro-organisms, and the process is known as "nitrification." It should be clearly understood that the process of nitrification may, so to speak, dovetail with the process of denitrification.—NEWMAN *Bacteria*, ch. 5, p. 152. (G. P. P., 1899.)

2427. NOTES OF SONG-BIRD—*Tuned to Soaring and Falling Motion.*—He [the South-American field-finch] sits perched on a stalk above the grass, and at intervals soars up forty or fifty yards high; rising, he utters a series of long, melodious notes; then he descends in a graceful spiral, the set of the motionless wings giving him the appearance of a slowly falling parachute; the voice then also falls, the notes coming lower, sweeter, and more expressive until he reaches the surface. After alighting, the song continues, the strains becoming longer, thinner, and clearer, until they dwindle to the finest threads of sound and faintest tinklings, as from a cithern touched by fairy fingers. The great charm of the song is in this slow gradation from the somewhat throaty notes emitted by the bird when ascending to the excessively attenuated sounds at the close. —HUDSON *Naturalist in La Plata*, ch. 19, p. 275. (C. & H., 1895.)

2428. NUMBER OF OBJECTS POSSIBLE IN CONSCIOUSNESS—Consciousness will be at its maximum of intensity when attention is concentrated on a single object; and the question comes to be, how many single objects can the mind simultaneously survey, not with vivacity, but without absolute confusion? I find the problem stated and differently answered by different philosophers, and apparently without a knowledge of each other. By Charles Bonnet the mind is allowed to have a distinct notion of six objects at once; by Abraham Tucker the number is limited to

four, while Destutt-Tracy again amplifies it to six. The opinion of the first and last of these philosophers appears to me correct. You can easily make the experiment for yourselves, but you must beware of grouping the objects into classes. If you throw a handful of marbles on the floor you will find it difficult to view at once more than six or seven at most, without confusion: but if you group them into twos or threes or fives you can comprehend as many groups as you can units, because the mind considers these groups only as units—it views them as wholes, and throws their parts out of consideration.—HAMILTON *Metaphysics*, lect. 14, p. 176. (Sh. & Co., 1859.)

2429. ——— ——— Experiments . . . show that four and sometimes even five disconnected impressions (letters, numerals, or lines of different direction) may be distinctly perceived. If the separate impressions are so arranged that they enter into combination with one another in idea, the number becomes three times as great. Thus we are able to cognize instantly two dissyllabic words of six letters each.—WUNDT *Psychology*, lect. 16, § 2, p. 343. (Son. & Co., 1896.)

2430. NURSERY, RIMES OF, AS HISTORY—*Cradle in Tree-top.*—The first engine was run by man-power; then man subdued the horse, the ass, the camel, and invented engines for those to propel. He next domesticated the winds, the waters, the steam, the lightning; but the first common carriers and machine-power were men and women. The first burden train was women's backs; the first passenger-car was a papoose-frame. And even now, while I am speaking to you, more heavy loads are resting on human shoulders than upon all the pack-animals in the world. Hence our nursery rime:

Rock a by baby on a tree-top,
When the wind blows
The cradle will rock.
When the bough bends
The cradle will fall.
Down will come cradle,
And baby and all.

The poetry of to-day is the fact of yesterday, the dream of yesterday is the fact of to-day. When the savage woman a century or two ago, upon this very spot, strapped her dusky offspring to a rude frame, hung it upon the nearest sapling for the winds to rock, or lifted the unfortunate suckling from the ground to which it had been hurled by the bending of an unsafe bough, that was a fact, a stage in the history of invention. In our nowadays couches of down, swung from gilded hinges, we have got far ahead of the papoose-cradle, the memory of which we perpetuate in nursery rimes sung to children, who wonder why babies should be hung in the tops of trees, and think, doubtless, that the falling cradle was a just retribution on the silly parents.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891, Proceedings of the Congress*, p. 408).

2431. NUTRITION, RESPONSE OF PLANT TO—*Rapid Absorption of Nutritious Matter by Sundew Leaf—Neglect of Useless Material.*—That the glands [of the sundew leaf] possess the power of absorption is shown by their almost instantaneously becoming dark colored when given a minute quantity of carbonate of ammonia, the change of color being chiefly or exclusively due to the rapid aggregation of their contents. When certain other fluids are added they become pale colored. Their power of absorption is, however, best shown by the widely different results which follow, from placing drops of various nitrogenous and non-nitrogenous fluids of the same density on the glands of the disk, or on a single marginal gland, and likewise by the very different lengths of time during which the tentacles remain inflected over objects which yield or do not yield soluble nitrogenous matter. This same conclusion might indeed have been inferred from the structure and movements of the leaves, which are so admirably adapted for capturing insects.—DARWIN *Insectivorous Plants*, ch. 1, p. 14. (A., 1900.)

2432. OAK THE MODEL FOR THE EDDYSTONE—*The Engineering of Nature.*—To what example, then, can we look? What better can we wish for than is supplied by that wonderful edifice which, for more than a century, braving the violence of the most destructive storms, has calmly and unintermittingly displayed its guiding light to the wave-tossed mariner, and which has furnished the pattern of every similar beacon elsewhere erected for the direction and warning of the navigator? I need not tell you to what I refer; for Smeaton and the Eddystone are household words to every Briton. . . . It was to Nature, not to the time-honored traditions of his profession, that this great practical philosopher went, when he had to deal with the problem of the Eddystone. He saw in the bole of the oak, which had stood the blasts of centuries, the shape that would not only give to his tower the greatest inherent strength, but would project upwards instead of directly resisting the dash of the impetuous waves. And he then brought all the resources of constructive skill to carry out this sagacious design, erecting on a broad and solid foundation that beautifully formed superstructure, which not only bears aloft the far-shining and welcome light, but serves as the dwelling-place for those who are charged with its maintenance.—CARPENTER *Nature and Man*, lect. 7, p. 212. (A., 1889.)

2433. OBJECTION TO NEBULAR HYPOTHESIS—*Impossible Cohesion Required of Gaseous Mass—Would Give Meteors In-*

stead of Planets.—It was objected by Professor Kirkwood in 1869 that there could be no sufficient cohesion in such an enormously diffused mass as the planets are supposed to have sprung from, to account for the wide intervals between them. The matter separated through the growing excess of centrifugal speed would have been cast off, not by rarely recurring efforts, but continually, fragmentarily, *pari passu* with condensation and acceleration. Each wisp of nebula, as it found itself unduly hurried, would have declared its independence, and set about revolving and condensing on its own account. The result would have been a meteoric, not a planetary system.—CLERKE *History of Astronomy*, pt. ii, ch. 9, p. 382. (Bl., 1893.)

2434. ——— ——— *Involves Retrograde Motion of All Planets.*—M. Faye's leading contention is that, under the circumstances assumed by Laplace, not the two outer planets alone, but the whole company must have been possessed of retrograde rotation. For they were formed—*ex hypothesi*—after the sun; central condensation had reached an advanced stage when the rings they were derived from separated; the principle of inverse squares consequently held good, and Kepler's laws were in full operation. Now particles circulating in obedience to these laws can only—since their velocity decreases outward from the center of attraction—coalesce into a globe with a backward axial movement. Nor was Laplace blind to this flaw in his theory; but his effort to remove it, tho it passed muster for the best part of a century, was scarcely successful. His planet-forming rings were made to rotate all in one piece, their outer parts thus necessarily traveling at a swifter linear rate than their inner parts, and eventually uniting, equally of necessity, into a forward-spinning body. The strength of cohesion involved may, however, safely be called impossible, especially when it is considered that nebulous materials were in question.—CLERKE *History of Astronomy*, pt. ii, ch. 9, p. 383. (Bl., 1893.)

2435. OBJECTS HELP REALIZATION—*Portraits and Toys—Explanation of Tendency to Idol-worship.*—Who does not "realize" more the fact of a dead or distant friend's existence at the moment when a portrait, letter, garment, or other material reminder of him is found? The whole notion of him then grows pungent and speaks to us and shakes us in a manner unknown at other times. In children's minds, fancies and realities live side by side. But however lively their fancies may be, they still gain help from association with reality. The imaginative child identifies its *dramatis personæ* with some doll or other material object, and this evidently solidifies belief, little as it may resemble what it is held to stand for. A thing not too interesting by its own real qualities generally does the best service here. The most useful doll I ever saw was a large cucumber in the hands of a little Amazonian-Indian girl; she nursed it and washed it and rocked it to sleep in a hammock, and talked to it all day long—there was no part in life which the cucumber did not play.—JAMES *Psychology*, vol. ii, ch. 21, p. 303. (H. H. & Co., 1899.)

2436. OBLIGATION TO MORALITY A PRIMAL CONVICTION—*All Attempts at Explanation Vain.*—Just as in the physical world there are bodies or substances which are (to us) elementary, so in the spiritual world there are perceptions, feelings, or emotions which are equally elementary—that is to say, which resist all attempts to resolve them into a combination of other and simpler affections of the mind. And of this kind is the idea, or the conception, or the sentiment of obligation. That which we mean when we say, "I ought," is a meaning which is incapable of reduction. It is a meaning which enters as an element into many other conceptions, and into the import of many other forms of expression, but it is itself uncompounded. All attempts to explain it do one or other of these two things—either they assume and include the idea of obligation in the very circumlocutions by which they profess to explain its origin, or else they build up a structure which, when completed, remains as destitute of the idea of obligation as the separate materials of which it is composed. In the one case, they first put in the gold, and then they think that by some alchemy they have made it; in the other case, they do not indeed first put in the gold, but neither in the end do they ever get it. No combination of other things will give the idea of obligation, unless with and among these things there is some concealed or unconscious admission of itself.—ARGYLL *Unity of Nature*, ch. 9, p. 191. (Burt.)

2437. OBLITERATION OF INSTINCT IN HEMISPHERELESS PIGEONS—Schrader gives a striking account of the instinctless condition of his brainless pigeons, active as they were in the way of locomotion and voice. "The hemisphereless animal moves in a world of bodies which . . . are all of equal value for him. . . . He is, to use Goltz's apt expression, impersonal. . . . Every object is for him only a space-occupying mass; he turns out of his path for an ordinary pigeon no otherwise than for a stone. He may try to climb over both. All authors agree that they never found any difference, whether it was an inanimate body, a cat, a dog, or a bird of prey which came in their pigeon's way. The creature knows neither friends nor enemies; in the thickest company it lives like a hermit. . . . As the male pays no attention to the female, so she pays none to her young. The brood may follow the mother, ceaselessly calling for food, but they might as well ask it from a

stone. . . . The hemisphereless pigeon is in the highest degree tame, and fears man as little as cat or bird of prey."—JAMES *Psychology*, vol. i, ch. 2, p. 77. (H. H. & Co., 1899.)

2438. OBSERVATION MISINTERPRETED—*Ant Recognized by Mates after Absence—Recognition Specific, Not Individual.*—How easy it is to misinterpret an observation if the very greatest care is not taken in recording it, and if it is impossible to vary the circumstances by experiment, and so obtain accurate knowledge of its conditions, is well shown by the following facts: Pierre Huber, one of the most reliable students of the habits of ants, stated that he had assured himself that an ant, if taken from the nest and returned after an interval of four months, was recognized by its former companions; for they received it friendlily, while members of a different nest, even tho they belonged to the same species, were driven away. Huber regards this as evidence of the extraordinary accuracy of memory in these insects. Now the correctness of his observation cannot be doubted; and, besides, it has been confirmed by another experienced investigator—Sir John Lubbock [Lord Avebury]. At first sight, therefore, the conclusion seems perfectly justifiable. But if a single individual were really recognized after so long an interval, think what the general mental capacity of the ants must be! Fortunately, Lubbock made the matter a subject of experiment. He took ant larvæ from the nest and did not put them back again till they were fully developed. The result was that they too were quite friendlily received. Plainly, then, there can be no question of an act of individual recognition. There must be some characteristic peculiar to all the members of a particular nest, possibly a specific odor, which determines the instinctive expression of "friendship."—WUNDT *Psychology*, lect. 23, § 1, p. 344. (M., 1898.)

2439. OBSERVATION, SCIENCE TEACHES CORRECT HABITS OF—*Mind as an Orderly Storehouse.*—To observe rightly and truly, and as science teaches us to observe, is a habit which lies at the foundation of all order in mental things; and without this habit of looking at things in their due sequence, thoughts and thinking can only appear as acts and processes which exist but to confuse and bewilder the thinker. And to the young, in their responsible duty—too little thought of in its serious nature both by pupil and teachers—of 'laying up stores of mental wealth for future use, how great a boon must be the acquirement of these orderly habits in the work of the mind! The great difficulty, I presume, of every educator of youth is not to arouse his pupils' thoughts, not to incite them to think, but to train them so to think that they shall understand, appreciate for themselves, and in due order arrange, for future use, the material which their education furnishes. For the well-balanced mind is like a duly arranged storehouse, where the fruits of each year's industry are not only duly arranged within, but are capable of being brought forth for use in good order and at the proper season and time.—ANDREW WILSON *Science-Culture for the Masses*, p. 28. (Hum., 1888.)

2440. OBSTACLES UNIMAGINED—*Boats Checked by Floating Rock—Drifting Pumice Covering the Sea.*—Every one is familiar with the fact that pumice floats upon water; this it does, not because it is a material specifically lighter than water, but because cavities filled with air make up a great part of its bulk. If we pulverize pumice we find the powder sinks readily in water, but the rock in its natural condition floats for the same reason that an iron ship does—because of the air-chambers which it encloses. When this pumice is ejected from a volcano and falls into a river or the ocean, it floats for a long time, till decomposition causes the breaking-down of the thin glassy partitions between the air-chambers, and causes the admission of water into the latter, by which means the whole mass gets water-logged. Near the Liparis and other volcanic islands the sea is sometimes covered with fragments of pumice to such an extent that it is difficult for a boat to make progress through it, and the same substance is frequently found floating in the open ocean and is cast up on every shore.—JUDD *Volcanoes*, ch. 4, p. 73. (A., 1899.)

2441. OBSTACLES, WAVES OF LIGHT FLOW AROUND—*Newton's Objection Answered—Diffraction.*—Newton, who was familiar with the idea of an ether, and who introduced it in some of his speculations, objected [nevertheless] that if light consisted of waves, shadows could not exist, for that the waves would bend round the edges of opaque bodies and agitate the ether behind them. He was right in affirming that this bending ought to occur, but wrong in supposing that it does not occur. The bending is real, tho in all ordinary cases it is masked by the action of interference. This inflection of the light receives the name of diffraction.—TYNDALL *Light*, lect. 2, p. 80. (A., 1898.)

2442. OCCIDENT AND ORIENT UNITED BY MEDITERRANEAN—*The Sea a Bond of Union.*—That which has rendered the geographical position of the Mediterranean most beneficial in its influence on the intercourse of nations is the proximity of the eastern continent, where it projects into the peninsula of Asia Minor; the number of islands in the Ægean Sea, which have served as a means for facilitating the spread of civilization, and the fissure between Arabia, Egypt, and Abyssinia, through which the great Indian Ocean penetrates under the name of the Arabian Gulf or the

Red Sea, and which is separated by a narrow isthmus from the Delta of the Nile and the southeastern coasts of the Mediterranean. By means of all these geographical relations the influence of the sea as a connecting element was speedily manifested in the growing power of the Phenicians, and subsequently in that of the Hellenic nations, and in the rapid extension of the sphere of general ideas. Civilization, in its early seats in Egypt, on the Euphrates, and the Tigris, in Indian Pentapotamia and China, had been limited to lands rich in navigable rivers; the case was different, however, in Phenicia and Hellas. The active life of the Greeks, especially of the Ionian race, and their early predilection for maritime expeditions, found a rich field for its development in the remarkable configuration of the Mediterranean, and in its relative position to the oceans situated to the south and west.—HUMBOLDT *Cosmos*, vol. ii, p. 122. (H., 1897.)

2443. OCEAN BLOCKADED BY FLOATING ROCK—*A Raft of Pumice.*—During the year 1878 masses of floating pumice were reported as existing in the vicinity of the Solomon Isles, and covering the surface of the sea to such extent that it took ships three days to force their way through them. Sometimes these masses of pumice accumulate in such quantities along coasts that it is difficult to determine the position of the shore within a mile or two, as we may land and walk about on the great floating raft of pumice.—JUDD *Volcanoes*, ch. 4, p. 73. (A., 1899.)

2444. OCEAN, FREEDOM OF COMMUNICATION IN—*Fauna of the Sea—More Difficult to Divide than That of the Land.*—On the dry land we find mountain ranges, forests, deserts, and other barriers that to a very considerable extent prevent the mixing of one fauna with another, but in the sea there are no barriers of anything like the same importance, but one fauna gradually merges into the neighboring fauna according to the temperature, the pressure, the amount of light, the salinity of the water, or the food-supply. This, then, is one of the difficulties met with in the study of the geographical distribution of the marine fauna.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 46. (A., 1894.)

2445. OCEAN, PHOSPHORESCENCE OF—*Manifold Light and Life of the Deep.*—As the moon passes behind a cloud, and the night grows darker for the obscuring of the Queen of the Night, this strange light on the waves literally glows with its fiery sheen. . . . Look how every fleck of spray seems tinged with a radiance as of jeweled kind. Flashes of lambent fire play among the foam, and now and then a long ripple of flame shoots along the whole course of the wave that rushes aft from the bow.

Suppose you could lift a bucket of water from the sea to-night, and that in your deck-cabin you had your microscope in full array, let us endeavor to see what such a scrutiny of the waves would tell us about the cause of the phosphorescence of the deep. The water would be seen to be alive with animalcules, each the mere fraction of an inch in length. . . .

Swarming in myriads in the waters of the ocean, these animalcules, under favorable conditions of heat and other phases relating to their vital activity, give forth the strange, weird gleam you see shooting along the crest of the waves. You can recall Coleridge's lines with apt force when on this quiet night you sit and watch the play of phosphorescence on the sea:

> Beyond the shadow of the ship I watched the water-snakes;
> They moved in tracks of shining white,
> And when they neared the elfish light
> Fell off in hoary flakes.
>
> Beyond the shadow of the ship I watched their rich attire;
> Blue, glossy green, and velvet black,
> They coiled and swam, and every track
> Was a flash of golden fire.

How and why these and other animals exhibit a phosphorescent light is a problem towards the solution of which science has, at least, advanced within reasonable distance. The noctiluca is undoubtedly the cause of the diffused phosphorescence of the sea. The myriads of animalcules give to the ocean the appearance of a universal effulgence.—ANDREW WILSON *Glimpses of Nature*, ch. 2, p. 11. (Hum., 1892.)

2446. ——— ——— *Night Made Glorious—Luxuriance of Beauty.*—The phosphorescence of the ocean is one of those splendid phenomena of Nature which excite our admiration, even when we behold its recurrence every night for months together. The ocean is phosphorescent in all zones of the earth, but he who has not witnessed the phenomenon in the tropics, and especially in the Pacific, can form but a very imperfect idea of the majesty of this brilliant spectacle. The traveler on board a man-of-war, when plowing the foaming waves before a fresh breeze, feels that he can scarcely satisfy himself with gazing on the spectacle presented by the circling waves. Wherever the ship's side rises above the waves, bluish or reddish flames seem to flash lightning-like upwards from the keel. The appearance presented in the tropical seas on a dark night is indescribably glorious, when shoals of dolphins are seen sporting around, and cutting the foaming waves in long and circling lines, gleaming with bright and sparkling light.—HUMBOLDT *Views of Nature*, p. 245. (Bell, 1896.)

2447. OCEAN, POSSIBLE IRRUPTION OF—The second case [of a possible deluge] is where there are large tracts of dry land beneath the mean level of

the ocean. It seems, after much controversy, to be at length a settled point that the Caspian is really 83 feet 6 inches lower than the Black Sea. As the Caspian covers an area about equal to that of Spain, and as its shores are in general low and flat, there must be many thousand square miles of country less than 83 feet above the level of that inland sea, and consequently depressed below the Black Sea and Mediterranean. This area includes the site of the populous city of Astrakhan and other towns. Into this region the ocean would pour its waters, if the land now intervening between the Sea of Azof and the Caspian should subside. Yet even if this event should occur, it is most probable that the submergence of the whole region would not be accomplished simultaneously, but by a series of minor floods, the sinking of the barrier being gradual.—LYELL *Principles of Geology*, bk. i, ch. 10, p. 156. (A., 1854.)

2448. OCEAN DEPTHS SUPPOSED TO BE LIFELESS—Our knowledge of the natural history of the deep seas may be said to have commenced not more than fifty years ago. There are, it is true, a few fragments of evidence of a fauna existing in depths of more than a hundred fathoms to be found in the writings of the earlier navigators, but the methods of deep-sea investigation were so imperfect in those days that naturalists were disposed to believe that in the abysses of the great oceans life was practically non-existent.—HICKSON *Fauna of the Deep Sea*, ch. 1, p. 2. (A., 1894.)

2449. OCEAN FLOOR OF THE NORTH ATLANTIC—*A Vast Plain—Depths Where Mont Blanc Might Be Sunk.*—The result of all these operations [soundings for the cable] is that we know the contours and the nature of the surface-soil covered by the North Atlantic, for a distance of 1,700 miles from east to west, as well as we know that of any part of the dry land. It is a prodigious plain—one of the widest and most even plains in the world. If the sea were drained off you might drive a wagon all the way from Valentia, on the west coast of Ireland, to Trinity Bay, in Newfoundland. And, except upon one sharp incline about 200 miles from Valentia, I am not quite sure that it would even be necessary to put the skid on, so gentle are the ascents and descents upon that long route. From Valentia the road would lie down-hill for about 200 miles to the point at which the bottom is now covered by 1,700 fathoms of sea-water. Then would come the central plain, more than a thousand miles wide, the inequalities of the surface of which would be hardly perceptible, tho the depth of water upon it now varies from 10,000 to 15,000 feet; and there are places in which Mont Blanc might be sunk without showing its peak above water. Beyond this, the ascent on the American side commences and gradually leads for about 300 miles to the Newfoundland shore.—HUXLEY *Lay Sermons*, serm. 14, p. 182. (G. P. P., 1899.)

2450. OLD AND NEW UNITE TO MAKE CONSISTENT SYSTEM—The great merit of Cope's work on mammals is that he always considered the old and new—the extinct and recent—forms together. He refused to be bound by consistency or by precedent, either set by himself or others. Fresh discoveries opened new vistas to him, and he modified his views from time to time and as often as he received new evidence.—GILL *Address in Memory of Edward Drinker Cope* in *Proceedings of Amer. Assoc. for Advancement of Science*, vol. xlvi, 1897.

2451. OMEN FULFILS ITSELF—*Halley's Comet at Battle of Hastings.*—The comet of Halley appeared again in 1066, at the time when William the Conqueror invaded England. The chroniclers unanimously write, "The Normans, guided by a comet, invaded England." The Duchess-Queen Matilda, wife of William, has represented this comet and the amazement of her subjects on the tapestry (230 feet long), which may be seen at Bayeux. Queen Victoria has in her crown a jewel the design of which was suggested by the tail of this comet, which had the greatest influence on the victory at Hastings.—FLAMMARION *Popular Astronomy*, bk. v, ch. 1, p. 479. (A.)

2452. OMEN REVERSED BY SCIENCE—*Serviceableness of the Screech-owl.*—We do not think of owls as being insectivorous birds, but Dr. A. K. Fisher tells us that of 225 screech-owls' stomachs examined, 100 contained insects. As 91 of the remaining 125 contained mice, and poultry was found in only one stomach, the farmer may well consider the screech-owl a bird of good repute rather than of ill omen.—CHAPMAN *Bird-Life*, ch. 7, p. 130. (A., 1900.)

2453. OMISSION BY ANCIENT WRITER—*A Common Bird Left without Mention.*—It is a remarkable fact that Molina, tho describing in detail all the birds and animals of Chile, never once mentions this genus [*Pteroptochos*], the species of which are so common and so remarkable in their habits. Was he at a loss how to classify them, and did he consequently think that silence was the more prudent course? It is one more instance of the frequency of omissions by authors, on those very subjects where it might have been least expected.—DARWIN *Naturalist's Voyage around the World*, ch. 12, p. 271 (note). (A., 1893.)

2454. OMNISCIENCE IS FOREKNOWLEDGE—*One Knowing All Factors of Decision Could Predict Result.*—Processes [of will] may be compared to a man on a journey who proceeds from a certain point on foot by short stages, at any given time,

and in any direction. He has then the choice of an infinite number of routes over the whole earth. If such a man begins his wanderings in obedience to the impulse of his own will, his own pleasure or interest—proceeding forwards, to the right or left, or even backwards, with longer or shorter pauses, and starting at any particular time—it is obvious that the route taken lies in the man himself and is determined by his own peculiar temperament. His judgment, experience, and inclination will influence his course at each turn of his journey, as new circumstances arise. He will turn aside from a mountain which he considers too lofty to be climbed; he will incline to the right if this direction appears to afford a better passage over a swollen stream; he will rest when he reaches a pleasant halting-place, and will hurry on when he knows that enemies beset him. And in spite of the perfectly free choice open to him, the course he takes is in fact decided by both the place and time of his starting and by circumstances which—always occurring at every part of the journey—impel him one way or the other; and if all the factors could be ascertained in the minutest detail his course could be predicted from the beginning.—WEISMANN *Heredity*, vol. i, p. 138. (Cl. P., 1891.)

2455. ONTOGENESIS AND PHYLOGENESIS—*Embryological Development Not Parallel with Geological.*—*Ontogenesis* is the embryonic development of the individual animal, and is, of course, a short process, depending on the production of a germ by a parent animal or parent pair, and the further growth of this germ in connection more or less with the parent or with provision made by it. This is, of course, a fact open to observation and study, tho some of its processes are mysterious and yet involved in doubt and uncertainty. *Phylogenesis* is the supposed development of a species in the course of geological time and by the intervention of long series of species, each in its time distinct and composed of individuals each going regularly through a genetic circle of its own.

The latter is a process not open to observation within the time at our command—purely hypothetical, therefore, and of which the possibility remains to be proved; while the causes on which it must depend are necessarily altogether different from those at work in *ontogenesis*, and the conditions of a long series of different kinds of animals, each perfect in its kind, are equally dissimilar from those of an animal passing through the regular stages from infancy to maturity. The similarity, in some important respects, of *ontogenesis* to *phylogenesis*, was inevitable, provided that animals were to be of different grades of complexity, since the development of the individual must necessarily be from a more simple to a more complex condition. On any hypothesis, the parallelism between embryological facts and the history of animals in geological time affords many interesting and important coincidences. Yet it is perfectly obvious that the causes and the conditions of these two successions cannot have been the same.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 65. (A. B. P. S.)

2456. OPINIONS ON AUTHORITY—*Agreement of Specialists the Test.*—It is, without doubt, the necessary condition of mankind to receive most of their opinions on the authority of those who have specially studied the matters to which they relate. The wisest can act on no other rule, on subjects with which they are not themselves thoroughly conversant; and the mass of mankind have always done the like on all the great subjects of thought and conduct, acting with implicit confidence on opinions of which they did not know, and were often incapable of understanding the grounds, but on which, as long as their natural guides were unanimous, they fully relied, growing uncertain and skeptical only when these became divided, and teachers who, as far as they could judge, were equally competent, professed contradictory opinions. Any doctrines which come recommended by the nearly universal verdict of instructed minds will no doubt continue to be, as they have hitherto been, accepted without misgiving by the rest.—MILL *Positive Philosophy of Auguste Comte*, p. 90. (H. H. & Co., 1887.)

2457. OPPORTUNITY IN LINE OF NATURAL TENDENCY—*A Time When Each Acquirement Is Easy.*—In all pedagogy the great thing is to strike the iron while hot, and to seize the wave of the pupil's interest in each successive subject before its ebb has come, so that knowledge may be got and a habit of skill acquired—a headway of interest, in short, secured, on which afterward the individual may float. There is a happy moment for fixing skill in drawing, for making boys collectors in natural history, and presently dissectors and botanists; then for initiating them into the harmonies of mechanics and the wonders of physical and chemical law. Later, introspective psychology and the metaphysical and religious mysteries take their turn; and, last of all, the drama of human affairs and worldly wisdom in the widest sense of the term. In each of us a saturation-point is soon reached in all these things; the impetus of our purely intellectual zeal expires, and unless the topic be one associated with some urgent personal need that keeps our wits constantly whetted about it, we settle into an equilibrium and live on what we learned when our interest was fresh and instinctive, without adding to the store.—JAMES *Psychology*, vol. ii, ch. 24, p. 401. (H. H. & Co., 1899.)

2458. OPPOSITES CONNECTED BY INSENSIBLE GRADATIONS—*Circle, Ellipse, Parabola, Hyperbola, Straight Line*

Merge into Each Other.—There is no apparent similarity between a straight line and a circle. The one is a curve; the other is defined as without curvature. The one encloses a space; the other will not enclose a space, tho produced forever. The one is finite; the other may be infinite. Yet, opposite as the two are in their characters, they may be connected together by a series of lines no one of which differs from the adjacent ones in any appreciable degree. Thus, if a cone be cut by a plane at right angles to its axis we get a circle. If, instead of being perfectly at right angles, the plane subtends with the axis an angle of 89° 59′, we have an ellipse which no human eye, even when aided by an accurate pair of compasses, can distinguish from a circle. Decreasing the angle minute by minute, this closed curve becomes perceptibly eccentric, then manifestly so, and by and by acquires so immensely elongated a form as to bear no recognizable resemblance to a circle. By continuing this process the ellipse changes insensibly into a parabola. On still further diminishing the angle the parabola becomes an hyperbola. And finally, if the cone be made gradually more obtuse, the hyperbola passes into a straight line as the angle of the cone approaches 180°. Here, then, we have five different species of line—circle, ellipse, parabola, hyperbola, and straight line —each having its peculiar properties and its separate equation, and the first and last of which are quite opposite in Nature, connected together as members of one series, all producible by a single process of insensible modification.—SPENCER *Biology*, pt. iii, ch. 3, p. 433. (A., 1900.)

2459. OPPOSITES UNITED—*The Luminiferous Ether Has Gascous Tenuity, with Properties of a Solid.*—The notion of this medium must not be considered as a vague or fanciful conception on the part of scientific men. Of its reality most of them are as convinced as they are of the existence of the sun and moon. The luminiferous ether has definite mechanical properties. It is almost infinitely more attenuated than any known gas, but its properties are those of a solid rather than of a gas. It resembles jelly rather than air. This was not the first conception of the ether, but it is that forced upon us by a more complete knowledge of its phenomena. A body thus constituted may have its boundaries; but, altho the ether may not be coextensive with space, it must at all events extend as far as the most distant visible stars. In fact, it is the vehicle of their light, and without it they could not be seen. This all-pervading substance takes up their molecular tremors, and conveys them with inconceivable rapidity to our organs of vision. It is the transported shiver of bodies countless millions of miles distant, which translates itself in human consciousness into the splendor of the firmament at night.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 4. (A., 1897.)

2460. OPPOSITION, DELIGHT IN—*Mental as Distinguished from Physical Combativeness—Perception of Dangers and Difficulties.*—There are individuals who never manifest the least degree of physical combativeness, who yet show a remarkable love of opposition in all their psychical relations with others. That objections will be raised by such persons to any plan that may be proposed we can always feel sure, tho we may not have the remotest idea as to what the objection may be in each particular case. Persons in whom this tendency exists in a less prominent degree are apt to see objections and difficulties first, altho their good sense may subsequently lead them to consider these as of less account or to be outweighed by the advantages of the scheme. Such was the case with the late Sir Robert Peel. On the other hand, those who are spoken of as of sanguine temperament are apt to lose sight of the intervening difficulties, in the pleasurable anticipation of the result.—CARPENTER *Mental Physiology*, ch. 7, p. 317. (A., 1900.)

2461. OPPRESSION HATEFUL—*Science Despises Tyrants' Petty Grandeur—Solicitude for Humanity.*—I have said that no arts of importance have been lost, but perhaps this assertion is rather too general. There is one which may be considered an exception: I allude to the ancient art possessed by the few of enslaving and brutalizing the many, the art by which a single individual, invested with the magic of kingly power, was enabled to compel thousands of his subjects, through the course of a long reign, like beasts of burden, to haul materials and heap up huge piles of stone, which might transmit to posterity the fact that a worm like himself had lived and died. The pyramids of Egypt, venerable as they are with the age of accumulated centuries, are melancholy monuments of human degradation, of human vanity and cruelty.—HENRY *Improvement of the Mechanical Arts, Scientific Writings*, vol. i, p. 321. (Sm. Inst., 1886.)

2462. ORDER AMID SEEMING ACCIDENTS—*Periodicity of Sun-spots.*—Schwabe found that in the course of about eleven years the solar spots pass through a complete cycle of changes. They become gradually more and more numerous up to a certain maximum, and then as gradually diminish. At length the sun's face becomes not only clear of spots, but a certain well-marked darkening around the border of his disk disappears altogether for a brief season. At this time the sun presents a perfectly uniform disk. Then gradually the spots return, become more and more numerous, and so the cycle of changes is run through again.

The astronomers who have watched the sun from the Kew Observatory have found

that the process of change by which the spots sweep in a sort of "wave of increase" over the solar disk is marked by several minor variations. As the surface of a great sea-wave will be traversed by small ripples, so the gradual increase and diminution in the number of the solar spots is characterized by minor gradations of change, which are sufficiently well marked to be distinctly cognizable. There seems every reason for believing that the periodic changes thus noticed are due to the influence of the planets upon the solar photosphere, tho in what way that influence is exerted is not at present perfectly clear.—PROCTOR *Other Worlds than Ours*, ch. 2, p. 39. (Burt.)

2463. ORDER OF EVOLUTION REVERSED—*Mental Disorder Wrecks Higher Structures First.*—We may, perhaps, express this point of connection between the illusions of normal life and insanity by help of a physiological hypothesis. If the nervous system has been slowly built up, during the course of human history, into its present complex form, it follows that those nervous structures and connections which have to do with the higher intellectual processes, or which represent the larger and more general relations of our experience, have been most recently evolved. Consequently, they would be the least deeply organized, and so the least stable; that is to say, the most liable to be thrown *hors de combat*. This is what happens temporarily in the case of the sane, when the mind is held fast by an illusion. And in states of insanity we see the process of nervous dissolution beginning with these same nervous structures, and so taking the reverse order of the process of evolution. And thus, we may say that throughout the mental life of the most sane of us these higher and more delicately balanced structures are constantly in danger of being reduced to that state of inefficiency which in its full manifestation is mental disease.—SULLY *Illusions*, ch. 6, p. 122. (A., 1897.)

2464. ORDER REQUIRES ORGANIZING MIND—*Philosophy an Antidote to Atheism.*—I had rather believe all the fables in the legend, and the Talmud and the Alcoran, than that this universal frame is without a mind; and, therefore, God never wrought miracle to convince atheism, because his ordinary works convince it. It is true that a little philosophy inclineth man's mind to atheism, but depth in philosophy bringeth men's minds about to religion; for while the mind of man looketh upon second causes scattered, it may sometimes rest in them and go no further; but when it beholdeth the chain of them confederate and linked together it must needs fly to Providence and Deity: nay, even that school which is most accused of atheism doth most demonstrate religion: that is, the school of Leucippus, and Democritus, and Epicurus; for it is a thousand times more credible that four mutable elements and one immutable fifth essence, duly and eternally placed, need no God, than that an army of infinite small portions, or seeds unplaced, should have produced this order and beauty without a divine marshal.—BACON *Essays*, essay 16, *Of Atheism*, p. 58. (W. L. A.)

2465. ORDER, UNCHANGING, OF THE STARRY HOST—*The Pleiades.*—When we look up at the heavens we see, if we watch through the night, the host of stars rising in the east and passing above us to sink in the west, always at the same distance and in unchanging order, each seeming a point of light as feeble as the glowworm's shine in the meadow over which they are rising, each flickering as tho the evening wind would blow it out. The infant stretches out its hand to grasp the Pleiades; but when the child has become an old man the "seven stars" are still there unchanged, dim only in his aged sight, and proving themselves the enduring substance, while it is his own life which has gone, as the shine of the glowworm in the night. They were there just the same a hundred generations ago, before the pyramids were built, and they will tremble there still, when the pyramids have been worn down to dust with the blowing of the desert sand against their granite sides. They watched the earth grow fit for man long before man came, and they will doubtless be shining on when our poor human race itself has disappeared from the surface of this planet.—LANGLEY *New Astronomy*, ch. 5, p. 117. (H. M. & Co., 1896.)

2466. ORGANISM DETERMINES DISEASE—*Bacteria Exciting Causes.*—Whatever may be said with regard to the power of micro-organisms to cause disease, we must understand one cardinal point, namely, that bacteria are never more than causes, for the nature of disease depends upon the behavior of the organs or tissues with which the bacteria or their products meet.—NEWMAN *Bacteria*, ch. 8, p. 267. (G. P. P., 1899.)

2467. ORGANISM MORE CONTROLLING THAN CONDITIONS—In variation under domestication there are two factors, namely, the nature of the organism and the nature of the conditions. The former seems to be much the more important; for nearly similar variations sometimes arise under, as far as we can judge, dissimilar conditions; and, on the other hand, dissimilar variations arise under conditions which appear to be nearly uniform.—DARWIN *Origin of Species*, ch. 1, p. 9. (Burt.)

2468. ORGANISMS, HIGHER, MAY COOPERATE WITH LOWER—Higher organisms [may be] associated for a specific purpose with bacteria. . . . [It is believed that these] perform a preliminary disintegration of organic matter before the decomposing bacteria commence their la-

bors. This occurs apparently in the self-purification of rivers, as well as in polluted soils.—NEWMAN *Bacteria*, ch. 1, p. 33. (G. P. P., 1899.)

2469. ORGANISMS, LOWER, HELP HIGHER—*Microbes Fix Nitrogen for Plants—Nitrates.*—Until comparatively recently it was held that plant life could not be maintained in a soil devoid of nitrogen or compounds thereof. But it has been found that certain classes of plants (the *Leguminosæ*, for example), when they are grown in a soil which is practically free from nitrogen at the commencement, do take up this gas into their tissues. One explanation of this fact is that free nitrogen becomes converted into nitrogen compounds in the soil through the influence of micro-organisms present there. Another explanation attributes this fixation of free nitrogen to micro-organisms existing in the rootlets of the plant. . . . The main supply of this gas, absolutely necessary to the existence of vegetable life upon the earth, is drawn not from the nitrogen of the atmosphere, but from that contained in nitrogen compounds in the soil. The most important of these are the nitrates. Here, then, we have the necessary food of plants expressed in a sentence: water, gases, salts, the most important and essential gas and some of the salts being combined in nitrates.—NEWMAN *Bacteria*, ch. 5, p. 147. (G. P. P., 1899.)

2470. ORGANISMS, MICROSCOPIC, INCONCEIVABLY NUMEROUS—*Protected Infusions Void of Life.*—Sixty flasks filled, boiled, and sealed [hermetically], and containing strong infusions of beef, mutton, turnip, and cucumber, are carefully packed in sawdust, and transported to the Alps. . . . We open our box at the Bel Alp and count out fifty-four flasks, with their liquids as clear as filtered drinking-water. In six flasks, however, the infusion is found muddy. We closely examine these, and discover that every one of them has had its fragile end broken off in the transit from London. Air has entered the flasks, and the observed muddiness is the result. . . . Examined with a pocket lens, or even with a microscope of insufficient power, nothing living is seen in the muddy liquid; but regarded with a magnifying power of a thousand diameters or so, what an astonishing appearance does it present! Leeuwenhoek estimated the population of a single drop of stagnant water at 500,000,000: probably the population of a drop of our turbid infusion would be this many times multiplied. The field of the microscope is crowded with organisms, some wabbling slowly, others shooting rapidly across the microscopic field. They dart hither and thither like a rain of minute projectiles; they pirouette and spin so quickly round that the retention of the retinal impression transforms the little living rod into a twirling wheel. And yet the most celebrated naturalists tell us they are vegetables. From the rod-like shape which they so frequently assume, these organisms are called "bacteria"—a term, be it here remarked, which covers organisms of very diverse kinds.—TYNDALL *Floating Matter of the Air*, essay 3, p. 292. (A., 1895.)

2471. ORGANISMS NEITHER PLANT NOR ANIMAL—*Moving Plants among Rooted Animals—Animals Secreting Chlorophyl—Plants Eating Insects.*—There is a limbo filled with organisms which never rise high enough in the scale to be manifestly either animal or plant, unless it may be said of some of them that they are each in turn and neither long. There are undoubted animals which produce the essential material of vegetable fabric, or build up a part of their structure of it, or elaborate the characteristic *leaf-green* [chlorophyl] which, under solar light, assimilates inorganic into organic matter, the most distinguishing function of vegetation. On the other hand, there are plants—microscopic, indeed, but unquestionable—which move spontaneously and freely around and among animals that are fixed and rooted. And, to come without further parley to the matter in hand, while the majority of animals feed directly upon plants, "for 'tis their nature to," there are plants which turn the tables and feed upon them. Some, being parasitic upon living animals, feed insidiously and furtively; these, altho really cases in point, are not so extraordinary, and, as they belong to the lower orders, they are not much regarded, except for the harm they do. There are others, and those of the highest orders, which lure or entrap animals in ways which may well excite our special wonder, all the more so since we are now led to conclude that they not only capture but consume their prey.—GRAY *Darwiniana*, art. 10, p. 289. (A., 1889.)

2472. ORGANISMS, SOCIAL, IN ECONOMY OF NATURE—*Coral Reefs and Islands.*—As minute social organisms, the corals play an important part in the general economy of Nature, altho they do not, as people began to believe after Captain Cook's voyages of discovery, build up islands or enlarge continents from almost unfathomable depths of the ocean. They excite the liveliest interest, whether regarded as physiological objects, and as illustrating the various gradations of animal form, or in connection with the geography of plants and the geognostic relations of the earth's crust. According to the comprehensive views of Leopold von Buch, the whole Jura-formation consists of "large elevated coral-banks of the ancient world, surrounding at a certain distance the old mountain chains."—HUMBOLDT *Views of Nature*, p. 252. (Bell, 1896.)

2473. ORGANIZATION NOT THE CAUSE OF LIFE—*Vital Force Organizes Matter.*—We never see the phenomena of

life dissociated from organization. Yet the profoundest physiologists have come to the conclusion that organization is not the cause of life, but, on the contrary, that life is the cause of organization—life being something—a force of some kind, by whatever name we may call it—which precedes organization, and fashions it, and builds it up. This was the conclusion come to by the great anatomist Hunter, and it is the conclusion indorsed in our own day by such men as Dr. Carpenter and Professor Huxley—men neither of whom have exhibited in their philosophy any undue bias towards either theological or metaphysical explanations.—ARGYLL *Reign of Law*, ch. 2, p. 71. (Burt.)

2474. ORGANIZATION OF INDUSTRY—*Cooperative Building among Primitive Men.*—To drag the piles to the lake, and fix them firmly [as supports for lake-dwellings], must also have required much labor, especially when their number is considered. At Wangen alone M. Lohle has calculated that 50,000 piles were used; but we must remember that these were probably not all planted at one time nor by one generation. Wangen, indeed, was certainly not built in a day, but was, no doubt, gradually enlarged as the population increased. Herodotus informs us that the Pæonians [an ancient race of lake-dwellers] made the first platform at the public expense, but that, subsequently, at every marriage (and polygamy was permitted), the bridegroom was expected to add a certain number of piles to the common support.—AVEBURY *Prehistoric Times*, ch. 6, p. 177. (A., 1900.)

2475. ORGANIZATION OF LABOR—*Combination against Competition.*—A moment's consideration will convince us that the same necessities of labor which were found to determine so fatally the condition of women and children are necessities which apply without any abatement to the labor of adult men. . . . If a man is placed under such conditions that he cannot save his wife and child from exhausting labor it is certain that the same conditions will impose a like necessity upon himself. Nevertheless, Parliament has resolutely and wisely refused to interfere on his behalf. And why? Because the argument is that the adult man is able, or ought to be able, to defend himself. And so he can; but how? Only by combination. The "law" which results in excessive labor is the law of competition—that is, it is the attraction exerted upon the wills of a multitude of individual men by the rewards of labor. The pressure of this attraction can only be lightened by bringing those wills under the power of counter-motives, which may induce them to postpone, to some higher interest, the immediate appetites of gain. And this is the work which combination does.—ARGYLL *Reign of Law*, ch. 7, p. 221. (Burt.)

2476. ORGANS OF SENSE BEYOND MAN'S KEN—*Mysterious Power of Antennæ.*—The antennæ appear to be the most important of the sense-organs [of ants], as their removal produces an extraordinary disturbance in the intelligence of the animal. An ant so mutilated can no longer find its way or recognize companions, and therefore is unable to distinguish between friends and foes. It is also unable to find food, ceases to engage in any labor, and loses all its regard for larvæ, remaining permanently quiet and almost motionless. A somewhat similar disturbance, or rather destruction, of the mental faculties is observable as a result of the same mutilation in the case of bees.—ROMANES *Animal Intelligence*, ch. 3, p. 142. (A., 1899.)

2477. ORGANS, RUDIMENTARY—*A True Teleology—Unity of Plan.*—By the adoption of the Darwinian hypothesis, or something like it, which we incline to favor, many of the difficulties are obviated and others diminished. In the comprehensive and far-reaching teleology which may take the place of the former narrow conceptions, organs and even faculties, useless to the individual, find their explanation and reason of being. Either they have done service in the past, or they may do service in the future. They may have been essentially useful in one way in a past species, and, tho now functionless, they may be turned to useful account in some very different way hereafter. In botany several cases come to our mind which suggest such interpretation.—ASA GRAY *Darwiniana*, art. 13, p. 375. (A., 1889.)

2478. ——— ——— *Muscles for Moving the Ears in Man.*—Moreover, most of the higher animals possess muscles which are never employed; even man has such rudimentary muscles. Most of us are incapable of moving our ears as we wish, altho the muscles for this movement exist, and altho individual persons who have taken the trouble to exercise these muscles do succeed in moving their ears. It is still possible, by special exercise, by the persevering influence of the will upon the nervous system, to reanimate the almost extinct activity in the existing but imperfect organs, which are on the road to complete disappearance.—HAECKEL *History of Creation*, vol. i, ch. 1, p. 12. (K. P. & Co., 1899.)

2479. ——— ——— *One Vast Plan of Organic Life.*—These useless members, these rudimentary or aborted limbs which puzzled us so much, are parts of an universal plan. On this plan the bony skeletons of all living animals have been put together. The forces which have been combined for the molding of organic forms have been so combined as to mold them after certain types or patterns. And when comparative anatomy has revealed this fact as affecting all the animals of the existing world, another branch

of the same science comes in to confirm the generalization, and extend it over the innumerable creatures which have existed and have passed away. This one plan of organic life has never been departed from since time began.—ARGYLL *Reign of Law,* ch. 4, p. 117. (Burt.)

2480. ORGANS, STIMULUS, GROWTH, AND DECAY OF—*Some Laws in Pedagogy.*—"A vigorously used organ withdraws nourishment from the neighboring organs and hinders their development."

"An organ that is not used loses its energy."

"An organ overstrained easily becomes useless."

"When a single function suffers, all the others suffer with it, and harmonious development is out of the question."

"Organic development proceeds from the inner to the outer; the reverse process is impossible."

"Artificial stimulus to growth leads to decay."

"The separate functions succeed each other, but they do not appear simultaneously."

"Only that which develops slowly is capable of long development."—VAIHINGER *Address before Scientists.* (Translated for *Scientific Side-Lights.)*

2481. ORIGIN AND ANTIQUITY OF MAN—*Likeness to and Difference from Lower Animals—Unity of Nature a Unity of Plan.*—Man, when regarded merely as an organism, is closely related to the lower animals. His body is constructed on the same general plan with theirs. More especially, he is near akin to the other members of the class *Mammalia.* But we must not forget that even as an animal man is somewhat widely separated from his humbler relations. . . . It is easy to say that every bone, every muscle, every convolution of his brain, has its counterpart in the corresponding parts of an orang or a gorilla. But, admitting this, it is also true that every one of these parts is different, and that the aggregate of all the differences mounts up to an enormous sum total, more especially in relation to habits and to capacities for action. Those remarkable homologies or likenesses of plan which obtain in the animal kingdom are very wonderful, and the study of them greatly enlarges our conceptions of the unity of Nature; but we must never forget that such general agreements in plan cover the most profound differences in detail and in adaptation to use, and that, while they indicate a common type, this may rather point to a unity of design than to a mere accidental unity of descent.—DAWSON *Facts and Fancies in Modern Science,* lect. 4, p. 139. (A. B. P. S.)

2482. ORIGIN OF DEEP-SEA LIFE—*No Close Resemblance to Geologic Fauna.*—Whence came the curious creatures that live mostly in total darkness and can sustain without injury to their delicate and complicated organization the enormous pressure of the great depths? Are they the remnants of the fauna of shallow prehistoric seas that have reached their present position by the gradual sinking of the ocean basins? Or, are we to look upon the abysmal region as the nursery of the marine fauna, the place whence the population of the shallow waters was derived? Neither of these answers is supported by the facts with which we are now well acquainted. The fauna of the abysmal region does not show a close resemblance to that of any of the past epochs as revealed to us by geology, nor are we justified in assuming, without much stronger evidence than we now possess, that the oceans have undergone any such great depression as this first theory presupposes.—HICKSON *Fauna of the Deep Sea,* ch. 3, p. 54. (A., 1894.)

2483. ORIGIN OF GEOMETRY—*Man Loves to Divide Space.*—The whole science of geometry may be said to owe its being to the exorbitant interest which the human mind takes in lines. We cut space up in every direction in order to manufacture them.—JAMES *Psychology,* vol. ii, ch. 20, p. 150. (H. H. & Co., 1899.)

2484. ORIGIN OF MARINER'S COMPASS FOREVER LOST—*Magnetism Known, Polarity Unsuspected.*—How or when the tendency of a freely suspended magnet to set itself in a nearly north and south direction was first discovered is a question, the answer to which is probably forever lost. The civilized world remained in ignorance of the fact for nearly eighteen centuries after the attractive effect of the lodestone had become well known. Altho, as I have already stated, it is not impossible to conjecture that the phenomenon was familiar to the ancestors of primitive civilization, who, from the highlands of Central Asia, dispersed in many races over the earth; yet the knowledge came to the people of the Middle Ages anew, through the invention of the first and greatest of electrical instruments—the mariner's compass; first, in its utilization of the mysterious force existing in the magnet; greatest, in that it has contributed more than any other product of human intelligence to the progress and welfare of mankind.—PARK BENJAMIN *Intellectual Rise in Electricity,* ch. 3, p. 53. (J. W., 1898.)

2485. ORIGIN OF NAME "GORILLA"—*Voyage of Hanno from Carthage.*—About twenty-five centuries ago a voyager called Hanno is said to have sailed from Carthage, between the Pillars of Hercules—that is, through the Straits of Gibraltar—along the shores of Africa. "Passing the Streams of Fire," says the narrator, "we came to a bay called the Horn of the South. In the recess there was an island, . . .

having a lake, and in this there was another island full of wild men. But much the greater part of them were women with hairy bodies, whom the interpreters called 'Gorillas.' Pursuing them, we were not able to take the men; they all escaped, being able to climb the precipices, and defended themselves with pieces of rock. But three women, who bit and scratched those who led them, were not willing to follow. However, having killed them, we flayed them and conveyed the skins to Carthage. . . ."

In the opinion of many naturalists, the wild men of this story were the anthropoid or manlike apes which are now called gorillas, rediscovered recently by Du Chaillu. . . . I must confess these inferences seem to me somewhat open to question, and the account of Hanno's voyage only interesting in its relation to the gorilla as having suggested the name now given to this race of apes. It is not probable that Hanno sailed much further than Sierra Leone. . . . The behavior of the "wild men," again, does not correspond with the known habits of the gorilla.—PROCTOR *Pleasant Ways in Science*, p. 296. (L. G. & Co., 1895.)

2486. ORIGIN OF RELIGION—*Assumptions Regarding a Divine Being.*—Men have been very busy of late in speculating on the origin of religion. In asking this question they generally make, often as it seems unconsciously, one or other of two assumptions. One is the assumption that there is no God, and that it must have taken a long time to invent him. The other is that there is a God, but that men were born, or created, or developed, without any sense or feeling of his existence, and that the acquisition of such a sense must of necessity have been the work of time.—ARGYLL *Unity of Nature*, ch. 11, p. 265. (Burt.)

2487. ORIGIN OF STATES OF CONSCIOUSNESS UNKNOWN—It must be frankly confessed that in no fundamental sense do we know where our successive fields of consciousness come from, or why they have the precise inner constitution which they do have. They certainly follow or accompany our brain states, and, of course, their special forms are determined by our past experiences and education. But, if we ask just *how* the brain conditions them, we have not the remotest inkling of an answer to give.—JAMES *Talks to Teachers*, ch. 2, p. 16. (H. H. & Co., 1900.)

2488. ORIGIN OF VARIATIONS UNEXPLAINED—*Darwin Admits Profound Ignorance.*—Darwin does not pretend to have discovered any law or rule according to which new forms have been born from old forms. He does not hold that outward conditions, however changed, are sufficient to account for them. Still less does he connect them with the effort or aspirations of any organism after new faculties and powers. He frankly confesses that "our ignorance of the laws of variation is profound," and says that in speaking of them as due to chance he means only "to acknowledge plainly our ignorance of the cause of each particular variation." ["Origin of Species," p. 131 (first edition).] Again he says: "I believe in no law of necessary development." [Ibid., p. 351.] This distinction between Mr. Darwin's theory and other theories of development has not, I think, been sufficiently observed. His theory seems to be far better than a mere theory—to be an established scientific truth—in so far as it accounts, in part at least, for the success and establishment and spread of new forms *when they have arisen.* But it does not even suggest the law under which, or by which, or according to which such new forms are introduced.—ARGYLL *Reign of Law*, ch. 5, p. 130. (Burt.)

2489. ———— ———— *Natural Selection Not a Cause.*—It cannot be too often repeated that natural selection can produce nothing whatever, except the conservation or preservation of some variation otherwise originated. The true origin of species does not consist in the adjustments which help varieties to live and to prevail, but in those previous adjustments which cause those varieties to be born at all. Now what are these? Can they be traced or even guessed at? Mr. Darwin has a whole chapter on the "Laws of Variation": and it is here, if anywhere, that we look for any suggestion as to the physical causes which account for the origin as distinguished from the mere preservation of species. He candidly admits that his doctrine of natural selection takes cognizance of variations only after they have arisen, and that it regards those variations as purely accidental in their origin, or, in other words, as due to chance. This, of course, he adds, is a supposition wholly incorrect, and only serves "to indicate plainly our ignorance of the cause of each particular variation."—ARGYLL *Reign of Law*, ch. 5, p. 143. (Burt.)

2490. ORIGIN, SUPPOSED INDEPENDENT, OF SIMILAR STRUCTURES—Nor is it clear that the apes of the New World and those of the Old ever had any ape ancestors common to both. Possibly further discoveries in the Eocene deposits of North America (which are such veritable treasure-houses of relics of ancient life) will reveal to us the past existence of transitional forms between the monkeys of America and of Asia and Africa; but, in spite of all that has been published, this has not, to our minds, been done, and we think it quite possible that these two families have had different origins, and have come to resemble each other independently.—MIVART *Types of Animal Life*, ch. 1, p. 34. (L. B. & Co., 1893.)

2491. ORIGINATORS AND FOLLOWERS—*Brutes Not Inventive.*—Reflect a moment upon your own daily life and you will recognize two sets of activity, those which you originate, and those in which you follow suit. Animals can learn to follow suit, and to a very limited extent can originate. But it is the divine spark of originality which underlies every thought or device in this world. As one man invents a machine and others by thousands fall into the use of it, as the musician composes a song and millions sing it, so was it in the cradle-land of humanity: the inventor, touched with fire from the divine altar, set new examples to be followed.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891, Proceedings of the Congress,* p. 407).

2492. OSTRICH OF AMERICA—*The "Ship of the Wilderness"—Invisible by Protective Coloring.*—Among the feathered inhabitants of the pampas the grand archaic ostrich of America survives. . . .

The rhea possesses a unique habit, which is a puzzle to us, altho it probably once had some significance—namely, that of running, when hunted, with one wing raised vertically, like a great sail—a veritable " ship of the wilderness." In every way it is adapted to the conditions of the pampas. . . . Its commanding stature gives it a wide horizon; and its dim, pale, bluish-gray color assimilates to that of the haze, and renders it invisible at even a moderate distance. Its large form fades out of sight mysteriously, and the hunter strains his eyes in vain to distinguish it on the blue expanse. Its figure and carriage have a quaint majestic grace, somewhat unavian in character, and peculiar to itself. There are few more strangely fascinating sights in Nature than that of the old black-necked cock-bird, standing with raised agitated wings among the tall plumed grasses, and calling together his scattered hens with hollow boomings and long mysterious suspirations, as if a wind blowing high up in the void sky had found a voice.—HUDSON *Naturalist in La Plata,* ch. 1, p. 26. (C. & H., 1895.)

2493. OUTCASTS OF HUMANITY—*Evidence of Vanished Civilization—Figures on the Rocks.*—The South-American steppes are the boundaries of a European semi-civilization. To the north, between the mountain chain of Venezuela and the Caribbean Sea, lie, crowded together, industrial cities, clean and neat villages, and carefully tilled fields. Even a taste for arts, scientific culture, and a noble love of civil freedom have long since been awakened within these regions.

To the south, a drear and savage wilderness bounds the steppe. Forests, the growth of thousands of years, in one impenetrable thicket, overspread the marshy region between the rivers Orinoco and Amazon. Huge masses of lead-colored granite contract the beds of the foaming rivers. Mountains and forests reecho with the thunder of rushing waters, the roar of the tiger-like jaguar, and the dull rain-foreboding howl of the bearded ape. . . .

In this grand and wild condition of Nature dwell numerous races of men. Separated by a remarkable diversity of languages, some are nomadic, unacquainted with agriculture, and living on ants, gums, and earth, mere outcasts of humanity, . . . such as the Ottomaks and Jarures; others, for instance the Maquiritares and Macos, have settled habitations, live on fruits cultivated by themselves, are intelligent, and of gentler manners. Extensive tracts between the Cassiquiare and the Atabapo are inhabited solely by the tapir and social apes; not by man. Figures graven on the rocks . . . attest that even these deserts were once the seat of a higher civilization. They bear testimony, as do also the unequally developed and varying languages (which are amongst the oldest and most imperishable of the historical records of man), to the changing destinies of nations.—HUMBOLDT *Views of Nature,* p. 19. (Bell, 1896.)

2494. OUTLOOK ON THE UNIVERSE ENLARGED BY TELESCOPE—*Satellites of Jupiter and Ring of Saturn Discovered.*—The increased power of vision, yielded nearly two hundred and fifty years ago by the invention of the telescope, has afforded to the eye, as the organ of sensuous cosmical contemplation, the noblest of all aids toward a knowledge of the contents of space, and the investigation of the configuration, physical character, and masses of the planets and their satellites. The first telescope was constructed in 1608, seven years after the death of the great observer, Tycho Brahe. Its earliest fruits were the successive discovery of the satellites of Jupiter, the sun's spots, the crescent shape of Venus, the ring of Saturn as a triple planetary formation, . . . telescopic stellar swarms, and the nebulæ in Andromeda. In 1634, the French astronomer Morin, eminent for his observations on longitude, first conceived the idea of mounting a telescope on the index-bar of an instrument of measurement, and seeking to discover Arcturus by day. The perfection in the graduation of the arc would have failed entirely, or to a considerable extent, in affording that greater precision of observation at which it aimed, if optical and astronomical instruments had not been brought into accord, and the correctness of vision made to correspond with that of measurement. The micrometer application of fine threads stretched in the focus of the telescope, to which that instrument owes its real and invaluable importance, was first devised six years afterward (1640), by the young and talented Gascoigne.—HUMBOLDT *Cosmos,* vol. iii, p. 41. (H., 1897.)

2495. OWNERSHIP, SENSE OF, ESSENTIAL TO MENTAL HEALTH—The sense of ownership begins in the second year of life. Among the first words which an infant learns to utter are the words "my" and "mine," and woe to the parents of twins who fail to provide their gifts in duplicate. The depth and primitiveness of this instinct would seem to cast a sort of psychological discredit in advance upon all radical forms of communistic utopia. Private proprietorship cannot be practically abolished until human nature is changed. It seems essential to mental health that the individual should have something beyond the bare clothes on his back to which he can assert exclusive possession, and which he may defend adversely against the world.—JAMES *Talks to Teachers*, ch. 7, p. 55. (H. H. & Co., 1900.)

2496. PAIN DUE TO DISCORD OR EXCESS—*Conflict and Violence Distressing.*—Conflict and violence are two principal modes of painful stimulation, and explain a very considerable number of our pains. In most, if not in all, of the painful sensations of three of the senses—namely, touch, hearing, and sight—the pain is either discord or excess. The smarting acuteness of a blow on the skin, of a railway whistle close to the ear, of a glare of light, are due to the mere degree or excess of the stimulus. In hearing and in sight there are, in addition, the pains of discord. In the two remaining senses, taste and smell, we cannot make the same affirmation. We do not know what is the mode of nervous action in a bitter taste, as quinin or soot, and we cannot say that the transition from sweet to bitter is a transition from moderate stimulus to an excessive one. It may be that the power of the nerve is exhausted under a different kind of influence from mere violence of stimulation; but no certain knowledge exists on the subject. The same remarks apply to smell.—BAIN *Mind and Body*, ch. 4, p. 18. (Hum., 1880.)

2497. PAIN LATENT IN JOY—*Suffering and Sacrifice Conditions of the Highest Good—The Mother's Devotion.*—Do we not see that our natural feelings mislead us when they pronounce pleasant things to be the good ones, and the painful ones evil? So far from this being the case, things that we call painful, that are painful in our ordinary state, are essential conditions of our highest good. To us there could not be love without them. We could never have felt the joy, never have had even the idea, of love, if sacrifice had been impossible to us. In our truest and intense happiness that which is otherwise felt as pain is present. Pain, we may say, is latent in our highest state. It lies hidden and unfelt in the form of devoted sacrifice; but it is there, and it would make itself felt as pain if the love which finds joy in bearing it were absent. Take, for example, the offices rendered with joy by a mother to her babe; let the love be wanting, and what remains? Not mere indifference, but vexation, labor, annoyance. A gladly accepted pain is in the mother's love; it is in all love that does not contradict the name. To take away from us the possibility of that which we feel as pain were to take its best part from life, to render it almost—surely altogether—worthless. The possibility of love is given to us in our power of sacrifice, and loving brings the power into immediate action.—HINTON *The Mystery of Pain*, p. 21. (Hum., 1893.)

2498. PAINLESSNESS OF VIOLENT DEATH—*Livingstone and the Lion.*—In all cases in which persons have escaped after being seized by a lion or tiger they declare that they suffered little or no pain, physical or mental. A well-known instance is that of Livingstone, who thus describes his sensations when seized by a lion: "Starting and looking half round, I saw the lion just in the act of springing on me. I was upon a little height; he caught my shoulder as he sprang, and we both came to the ground below together. Growling horribly close to my ear, he shook me as a terrier dog does a rat. The shock produced a stupor similar to that which seems to be felt by a mouse after the first shake of the cat. It causes a sort of dreaminess, in which there was no sense of pain or feeling of terror, tho I was quite conscious of all that was happening. It was like what patients partially under the influence of chloroform describe, who see all the operation, but feel not the knife. This singular condition was not the result of any mental process. The shake annihilated fear, and allowed no sense of horror in looking round at the beast."—WALLACE *Darwinism*, ch. 2, p. 25. (Hum.)

2499. PAINTING, EGYPTIAN, CONVENTIONAL FETTERS OF—*Greek Pictures Excel in Freedom and Naturalness.*—In color-drawing or painting the Egyptian wall-paintings show a style half-way between the lowest and the highest. Here the scenes of old Egyptian life are caught at their characteristic moments, the shoemaker is seen drawing his thread, the fowler throwing at the ducks, the lords and ladies feasting, and the flute-players and tumblers performing before them. Yet with all their clever expressiveness, the Egyptian paintings have not quite left behind the savage stage of art. In fact, they are still picture-writings rather than pictures, repeating rows of figures with heads, legs, and arms drawn to pattern, and colored in childish daubs of color—hair all black, skin all red-brown, clothing white, and so on. The change from these to the Greek paintings is surprising; now we have no more rows of man-patterns, but grouped studies of real men. The best works of the Greek painters are only known to moderns by the admiring descriptions of the ancients, but more ordinary specimens

which have been preserved give an idea what the paintings of Zeuxis and Apelles may have been. The tourist visiting for the first time the museum of Naples comes with a shock of surprise in face of Alexander of Athens' picture of the goddesses at play, the boldly drawn frescos of scenes from the "Iliad," and the groups of dancers elegant in drawing and coloring. Most of these pictures from Herculaneum and Pompeii were done by mere house decorators, but these tenth-rate Greek painters had the traditions of the great classic school, and they show plainly that from the same source we also have inherited the art of design.—TYLOR *Anthropology*, ch. 12, p. 303. (A., 1899.)

2500. PAIRS, STRANGELY ASSORTED—*Bright Star with Dark Companion—Fitful and Intermittent Light.*—"Eclipse-stars" are actually found in the heavens. The best and longest-known member of the group is Algol in the head of Medusa, the "Demon-star" of the Arabs. This remarkable object, normally of the second magnitude, loses and regains three-fifths of its light once in 68.8 hours, the change being completed in about ten hours. Its definite and limited nature and punctual recurrence suggested to Goodricke of York, by whom the periodicity of the star was discovered in 1783, the interposition of a large, dark satellite. But the conditions involved by the explanation were first seriously investigated by Pickering in 1880. He found that the phenomena could be satisfactorily accounted for by supposing an obscure body 0.764 of the bright star's diameter to revolve round it in a period identical with that of its observed variation. This theoretical forecast was verified with singular exactitude at Potsdam in 1889.—CLERKE *History of Astronomy*, pt. ii, ch. 12, p. 469. (Bl., 1893.)

2501. PARABLE A NECESSITY—*Truth Veiled, Not Dismembered.*—Edward Irving [says]: "We must speak in parables, or we must present a wry and deceptive form of truth, of which choice the first is to be preferred, and our Lord adopted it. Because parable is truth veiled, not truth dismembered; and as the eye of the understanding grows more piercing, the veil is seen through, and the truth stands revealed." Nature is the great parable, and the truths which she holds within her are veiled, but not dismembered. The pretended separation between that which lies within Nature and that which lies beyond Nature is a dismemberment of the truth. Let both those who find it difficult to believe in anything which is "above" the natural, and those who insist on that belief, first determine how far the natural extends. Perhaps in going round these marches they will find themselves meeting upon common ground. For, indeed, long before we have searched out all that the natural includes, there will remain little in the so-called supernatural which can seem hard of acceptance or belief—nothing which is not rather essential to our understanding of this otherwise "unintelligible world."—ARGYLL *Reign of Law*, ch. 1, p. 32. (Burt.)

2502. PARADOX OF NATURE—*Glacier Preserved under Lava-stream.*—A remarkable discovery was made on Etna in 1828 of a great mass of ice, preserved for many years, perhaps for centuries, from melting, by the singular accident of a current of red-hot lava having flowed over it. The following are the facts in attestation of a phenomenon which must at first sight appear of so paradoxical a character. The extraordinary heat experienced in the south of Europe during the summer and autumn of 1828 caused the supplies of snow and ice which had been preserved in the spring of that year for the use of Catania . . . to fail entirely. . . . The magistrates of Catania applied to Signor M. Gemmellaro, in the hope that his local knowledge of Etna might enable him to point out some crevice or natural grotto on the mountain where drift-snow was still preserved. Nor were they disappointed; for he had long suspected that a small mass of perennial ice at the foot of the highest cone was part of a large and continuous glacier covered by a lava current. Having procured a large body of workmen, he quarried into this ice, and proved the superposition of the lava for several hundred yards, so as completely to satisfy himself that nothing but the subsequent flowing of the lava over the ice could account for the position of the glacier. . . . We may suppose that at the commencement of the eruption a deep mass of drift-snow had been covered by volcanic sand showered down upon it before the descent of the lava. A dense stratum of this fine dust mixed with scoriæ is well known to be an extremely bad conductor of heat; and the shepherds in the higher regions of Etna are accustomed to provide water for their flocks during summer, by strewing a layer of volcanic sand a few inches thick over the snow, which effectually prevents the heat of the sun from penetrating. Suppose the mass of snow to have been preserved from liquefaction until the lower part of the lava had consolidated, we may then readily conceive that a glacier thus protected, at the height of ten thousand feet above the level of the sea, would endure as long as the snows of Mont Blanc.—LYELL *Geology*, ch. 25, p. 412. (A., 1854.)

2503. PARALLAX OF STARS—*Difficulties that Beset the Problem—Patience and Exactness of Science.*—In the whole of sidereal astronomy there is, perhaps, nothing more difficult to determine than the parallax of a star. To think that among all the stars in the sky there is not one which shows a parallax of one second—that is to say, an annual motion of two seconds! Now, two seconds is a millimeter seen at a hundred meters, it is a hair of a tenth of a millimeter seen at 10 meters

(32.8 feet)! Well, it is in this width that the annual motion of a star is performed. The telescope magnifies it, of course; without this it would be absolutely imperceptible; but how easily it can be concealed by the imperceptible motions of the telescope, by the influences of temperature, by refraction, precession, nutation, aberration, and by the proper motion of the star itself in space! All these united influences amount to several seconds, and are themselves subject to some uncertainties, and instrumental errors must still be added to them. How, then, shall we extricate trustworthy indications of the minute displacement due to the effect of the earth's motion? Astronomers have, however, succeeded in doing so for some stars.—FLAMMARION *Popular Astronomy,* bk. v, ch. 5, p. 596. (A.)

2504. PARASITE, DEFINITION OF—*Food and Shelter at Second Hand.*—In general, we term every living creature a parasite, in the widest sense, that takes shelter and food within a living creature of another sort. The shelter may be temporary or permanent, and the food may either be derived directly from the fluids or the tissues of the host, or from his gains, or even from his secretions or excretions, and offal. The only requisite for being a parasite is that by nature it should be assigned to such a host that it must be unable to maintain existence without such an organism to entertain it, and it is immaterial whether the parasite is inconvenient or not to the host, or whether he causes any visible injury or not, or even whether he may be useful in any respect.—HELLER *Die Schmarotzer, mit besonderer Berücksichtigung der für den Menschen wichtigen,* p. 3. (Translated for *Scientific Side-Lights.*)

2505. PARASITE, INJURY TO SILKWORM FROM—If, in 1870, any one had affirmed that a miserable little insect from across the water were going to cause to France an injury of an importance pecuniarily equal to, in fact even greater than, that incurred by the war indemnity paid to Germany, people would have protested against such a prophecy as pessimistic—altogether nonsensical. Nevertheless, it is true, or at least will come true.—BEAULIEU, quoted, p. 204, in HELLER'S *Die Schmarotzer.* (Translated for *Scientific Side-Lights.*)

2506. PARASITISM A CAUSE OF DEGENERACY—Many groups of animals contain certain genera, families, or even whole orders, which live at the expense of other animals, feeding on their blood or tissues, yet not killing them after the manner of beasts of prey. Such are the parasites, some of which only seek their unwilling host when impelled by hunger, and leave it as soon as they are satisfied, while others take up their abode in or upon it, only to be driven thence by its death. The great group of worms includes very many parasites, and they are almost as numerous among the *Crustacea.* Most crustaceans are free-swimming or actively running inhabitants of the water, especially of the sea, and their food is partly of a vegetable nature and partly consists of living or dead animals; but nearly every order includes some parasitic form, in which the effects of disuse resulting from parasitism are plainly traceable.—WEISMANN *Heredity,* vol. ii, p. 10. (Cl. P., 1892.)

2507. ——— ——— *Inaction Entails Loss of Function—Idleness Ends in Degradation.*—That something of the lower nature often commingles with higher things is, unfortunately, a fact of life that needs no new illustration. Mistletoe is a "parasite" on apple and oak, and parasites belong to the groundlings among life's children. There is no nobility in the character of animal or plant which attaches itself to another living being, either as a lodger or a boarder, or in the double capacity of an unbidden guest. Plant morals, like animal morals, are often of the grossly utilitarian type. If a living being is cunning enough to take life easy by absorbing the food which another child of life prepares for its own use, the parasite doubtless benefits by its assumption of the rôle of unwelcome guest. . . . But there is a stern decree of that implacable female, Madre Natura, which declares that parasitism includes the lowering of the form which sacrifices its vital independence to luxurious comfort and inglorious ease. In animals, legs, stomachs, eyes, and other belongings are swept away when the parasite, attaching itself to another animal, is found to have no use for the organs of free and normal existence. This is the penalty of parasitism everywhere—degradation and backsliding in the vital scale.—ANDREW WILSON *Glimpses of Nature,* ch. 21, p. 69. (Hum., 1892.)

2508. PARSIMONY IN CONSCIOUSNESS—*Perceptions Needless to Notice Become Unconscious—The Goal Becomes All.*—It is a general principle in psychology that consciousness deserts all processes where it can no longer be of use. The tendency of consciousness to a minimum of complication is in fact a dominating law. The law of parsimony in logic is only its best known case. We grow unconscious of every feeling which is useless as a sign to lead us to our end. . . . So in acquiring any art or voluntary function. The marksman ends by thinking only of the exact position of the goal, the singer only of the perfect sound, the balancer only of the point of the pole whose oscillations he must counteract. The associated mechanism has become so perfect in all these persons that each variation in the thought of the end is functionally correlated with the one movement fitted to bring the latter about. Whilst they were tyros they thought of their means as well as their end: the marksman of the position of his

gun or bow or the weight of his stone; the pianist of the visible position of the note on the keyboard; the singer of his throat or breathing; the balancer of his feet on the rope, or his hand or chin under the pole. But little by little they succeeded in dropping all this supernumerary consciousness, and they became secure in their movements exactly in proportion as they did so.—JAMES *Psychology*, vol. ii, ch. 26, p. 496. (H. H. & Co., 1899.)

2509. PARTHENOGENESIS, NATURE FURNISHES INSTANCES OF—*Successive Generations of a Single Sex.*—One of the most remarkable deviations from the normal law of development is seen in the case of the little aphides, or plant-lice, the insects so familiar to all as the pests of the gardener. At the close of the autumn season winged males and females of these insects appear amongst their neighbor-aphides, and these produce eggs, which, however, lie dormant throughout the winter. Waking into life and development with the returning spring, these eggs give birth each to a wingless female, no insect of the sterner sex being found amongst the developed progeny of these insects. The presence of both sexes is throughout the animal world regarded as necessary for the production of eggs capable of developing into offspring. Strangely enough, however, these wingless females not only produce eggs, hatching them within their bodies, but the eggs develop into beings exactly resembling themselves, not a single male aphis being represented within the limits of this amazonian population. Seven, eight, nine, or even eleven generations of these wingless females may be produced in this manner, and the swarms of plant-lice which infest our vegetation attest the fertility of the race. But in the last brood of these insects, produced toward the close of autumn, winged males appear in addition to the females, which latter also possess wings. The members of this last brood produce eggs of ordinary nature, which lie dormant during the winter, but which in the succeeding spring will inaugurate the same strange life history through which their progenitors passed. . . . The law of heredity appears to operate in this instance in a somewhat abnormal, or at any rate in a very unusual manner. The true similitude of the winged parents is not attained until after the lapse of months, and through the interference, as it were, of many generations of dissimilar individuals.—ANDREW WILSON *The Law of Likeness*, p. 37. (Hum., 1888.)

2510. PARTICLES SMALLER THAN LIGHT-WAVES—*Microscope Does Not Reveal Them.*—Our best microscopes can readily reveal objects not more than $\frac{1}{50000}$ of an inch in diameter. This is less than the length of a wave of red light. Indeed, a first-rate microscope would enable us to discern objects not exceeding in diameter the length of the smallest waves of the visible spectrum. By the microscope, therefore, we can test our particles. If they be as large as the light-waves they will infallibly be seen; and if they be not so seen, it is because they are smaller. Some months ago I placed in the hands of our president a liquid containing Brücke's precipitate [of resin from alcoholic solution let fall in water]. The liquid was milky blue, and Mr. Huxley applied to it his highest microscopic power. He satisfied me that had particles of even $\frac{1}{100000}$ of an inch in diameter existed in the liquid they could not have escaped detection. But no particles were seen. Under the microscope the turbid liquid was not to be distinguished from distilled water.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 119. (A., 1897.)

2511. PARTICLES, SUPPOSED, OF LIGHT—*Newton's "Emission Theory"—Mistaken Analogy of Gravitation.*—Newton's conceptions regarding the nature of light were influenced by his previous knowledge. He had been pondering over the phenomena of gravitation, and had made himself at home amid the operations of this universal power. Perhaps his mind at this time was too freshly and too deeply imbued with these notions to permit of his forming an unfettered judgment regarding the nature of light. Be that as it may, Newton saw in refraction the action of an attractive force exerted on the light-particles. He carried his conception out with the most severe consistency. Dropping vertically downwards towards the earth's surface, the motion of a body is accelerated as it approaches the earth. Dropping in the same manner downwards on a horizontal surface, say through air on glass or water, the velocity of the light-particles, when they came close to the surface, was, according to Newton, also accelerated. Approaching such a surface obliquely, he supposed the particles, when close to it, to be drawn down upon it, as a projectile is drawn by gravity to the surface of the earth. This deflection was, according to Newton, . . . refraction. . . . Finally, it was supposed that differences of color might be due to differences in the size of the particles. This was the physical theory of light enunciated and defended by Newton; and you will observe that it simply consists in the transference of conceptions born in the world of the senses to a subsensible world.—TYNDALL *Lectures on Light*, lect. 2, p. 46. (A., 1898.)

2512. PARTICLES, VIEWLESS, OF ODOR—*Rotary Motion of Odorous Substances.*—Since the interesting discovery of Romieu, in 1756, that very small bits of camphor on the surface of water have a curious rotary motion, the same phenomenon has been noticed by a number of observers in several hundred odorous substances of either vegetable or animal structure. This, of course, strengthens the belief that the stimulus of

smell is thrown off from these substances in the form of invisible and imponderable particles. If paper be tied in front of the nostrils of dogs, they cannot "track" game or follow their masters by the sense of smell.—LADD *Psychology*, ch. 6, p. 100. (S., 1899.)

2513. PARTNERSHIP OF HEAT AND COLD—*Each in Turn Contributes to Purity of Milk.*—While the heating process is of course the essential feature of efficient pasteurization, it must not be forgotten that rapid and thorough cooling is almost equally important. . . . Pasteurization differs from complete sterilization in that it leaves behind a certain number of microbes or their spores. Cooling inhibits the germination and growth of this organismal residue. If after the heating process the milk is cooled and kept in a refrigerator, it will probably keep sweet from three to six days, and may do so for three weeks.—NEWMAN *Bacteria*, ch. 6, p. 211. (G. P. P., 1899.)

2514. PARTNERSHIPS IN THE VEGETABLE KINGDOM—*Combination for Mutual Advantage Not Parasitism.*—Bacterial life in several ways is able to reclaim from the atmosphere this free nitrogen, which would otherwise be lost. The first method to which reference may be made is that involving symbiosis. This term signifies "a living together" of two different forms of life, generally for a specific purpose. It may be to mutual advantage, a living for one another, or it may be, by means of an interchange of metabolism or products, finally to produce or obtain some remote chemical result. . . . The partnerships between hermit crabs and sea-anemones and the like are sometimes defined by the term commensalism (joint diet). Symbiosis and commensalism must be distinguished from parasitism, which indicates that all the advantage is on the side of the parasite, and nothing but loss on the side of the host. The distinction between symbiosis and commensalism cannot be rigid, but between these conditions, which are advantageous to the partners, and parasitism, there is an obvious and radical difference. The example of bacteriological symbiosis, with which we are concerned here, is that partnership between bacteria and some of the higher plants *(Leguminosæ)* for the purpose of fixing nitrogen in the plant and in the surrounding soil.—NEWMAN *Bacteria*, ch. 5, p. 162. (G. P. P., 1899.)

2515. PASSAGE FROM ONE KINGDOM TO ANOTHER IMPOSSIBLE—*Inorganic Shut from Organic; Natural from Spiritual.*—The passage from the natural world to the spiritual world is hermetically sealed on the natural side. The door from the inorganic to the organic is shut, no mineral can open it; so the door from the natural to the spiritual is shut, and no man can open it. This world of natural men is staked off from the spiritual world by barriers which have never yet been crossed from within. No organic change, no modification of environment, no mental energy, no moral effort, no evolution of character, no progress of civilization can endow any single human soul with the attribute of spiritual life. The spiritual world is guarded from the world next in order beneath it by a law of biogenesis—except a man be born again . . . he cannot enter the Kingdom of God.—DRUMMOND *Natural Law in the Spiritual World*, int., p. 64. (H. Al.)

2516. PASSING OF UNSEEN HOSTS—*The Nocturnal Journeys of Birds.*—This nocturnal journey of birds may also be studied from lighthouses. On September 26, 1891, I visited the Bartholdi Statue of the Goddess of Liberty, in New York Bay, for this purpose. The weather was most favorable. The first bird was observed at eight o'clock, and for the succeeding two hours others were constantly heard, tho comparatively few were seen. At ten o'clock it began to rain; and almost simultaneously there was a marked increase in the number of birds about the light, and within a few minutes there were hundreds where before there was one, while the air was filled with the calls of the passing host. From the balcony which encircles the torch the scene was impressive beyond description. We seemed to have torn aside the veil which shrouds the mysteries of the night, and with the searching light exposed the secrets of Nature. By far the larger number of birds hurried onward; others hovered before us, like humming-birds before a flower, then flew swiftly by into the darkness; and some, apparently blinded by the brilliant rays, struck the statue slightly, or with sufficient force to cause them to fall dead or dying. At daybreak a few stragglers were still winging their way southward, but before the sun rose the flight was over.—CHAPMAN *Bird-Life*, ch. 4, p. 57. (A., 1900.)

2517. PAST A GUIDE FOR FUTURE—*Volcanic Eruptions—Etna.*—However natural it may be that the force of running water in numerous valleys, and of tides and currents in many tracts of the sea, should now be spent, it is by no means so easy to explain why the violence of the earthquake and the fire of the volcano should also have become locally extinct at successive periods. We can look back to the time when the marine strata, whereon the great mass of Etna rests, had no existence; and that time is extremely modern in the earth's history. This alone affords ground for anticipating that the eruptions of Etna will one day cease.

> Will ever belch; for sulfer will expire
> —*Dryden's Trans.*]

are the memorable words which are put into the mouth of Pythagoras by the Roman poet, and they are followed by speculations as to the cause of volcanic vents shifting their positions. Whatever doubts the philosopher expresses as to the nature of these causes, it is assumed, as incontrovertible, that the points of eruption will hereafter vary, because they have formerly done so; a principle of reasoning which, as I have endeavored to show in former chapters, has been too much set at naught by some of the earlier schools of geology, which refused to conclude that great revolutions in the earth's surface are now in progress, or that they will take place hereafter, because they have often been repeated in former ages.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 345. (A., 1854.)

2518. PAST INHARMONIOUS WITH PRESENT SEEMS REMOTE—Thus, when we have lost something we cherished dearly, and the recollection of it brings fruitless longing, we instinctively seek to expel the recollection from our minds. The very feeling that what has been can never again be seems to induce this idea of a vast remoteness of the vanished reality. When, moreover, the lost object was fitted to call forth the emotion of reverence, the impulse to magnify the remoteness of the loss may not improbably be reenforced by the circumstance that everything belonging to the distant past is fitted on that account to excite a feeling akin to reverence. So, again, any rupture in our mental development may lead us to exaggerate the distance of some past portion of our experience. When we have broken with our former selves, either in the way of worsening or bettering, we tend to project these further into the past. —SULLY *Illusions*, ch. 10, p. 260. (A., 1897.)

2519. PAST, TRIUMPHS OF EVOLUTION IN THE—*Nature Always Succeeds—The Pledge of What Is To Be.*—All the other kingdoms of Nature culminated; evolution always attains; always rounds off its work. It spent an eternity over the earth, but finished it. It struggled for millenniums to bring the vegetable kingdom up to the flowering plants, and succeeded. In the animal kingdom it never paused until the possibilities of organization were exhausted in the mammalia. Kindled by this past, man may surely say, "I shall arrive." The further evolution must go on, the higher kingdom come—first the blade, where we are today; then the ear, where we shall be tomorrow; then the full corn in the ear, which awaits our children's children, and which we live to hasten.—DRUMMOND *Ascent of Man*, ch. 10, p. 346. (J. P., 1900.)

2520. PATH OF AMAZON SCOOPED FROM A VAST PLAIN—*Hills Mark Ancient Level.*—It is delightful to Mr. Agassiz, in returning to this locality, to find that phenomena, which were a blank to him on our voyage up the river, are perfectly explicable now that he has had an opportunity of studying the geology of the Amazonian Valley. When we passed these singular flat-topped hills before, he had no clue to their structure or their age, whether granite, as they have been said to be, or sandstone or limestone; whether primitive, secondary, or tertiary: and their strange form made the problem still more difficult. Now he sees them simply as the remnants of a plain which once filled the whole valley of the Amazons, from the Andes to the Atlantic, from Guiana to Central Brazil. Denudations on a colossal scale, hitherto unknown to geologists, have turned this plain into a labyrinth of noble rivers, leaving only here and there, where the formation has resisted the rush of waters, low mountains and chains of hills to tell what was its thickness.—AGASSIZ *Journey in Brazil*, ch. 12, p. 374. (H. M. & Co., 1896.)

2521. PATHWAYS FOR LIGHT THROUGH SOLIDS—*Magnetism Opens a Way.* —To the ether the glass is like a sieve, and so is any substance. Light-waves fly in straight lines. The openings through the glass are probably straight, so the light can pass directly through, but the openings through an opaque body are crooked; the molecules overlap in such a way that there is no direct line through the substance, hence the light will either be absorbed or reflected when it strikes upon an opaque body.

Some idea of what we mean by the overlapping of molecules may be had by the following experiment. Fill a tube with finely pulverized iron filings made into a thin paste. Let the two ends of the tube be stopped with glass heads. Throw a strong beam of light on one end so that the direction of the beam will be in the direction of the length of the tube. Place the tube into a helix (a coil of wire), and pass a current of electricity through the wire of the helix. Now so direct the arrangement that the beam of light strikes upon a screen, and a spot of light will appear on the screen as long as the current is passing; when the current is broken, the spot of light will disappear. The magnetism rearranges the particles of the naturally opaque mass of iron filings so that light can pass between them; they are transparent. When the current is taken off, the magnetism disappears, and the particles arrange themselves again in such a way as to shut off the light. The body becomes opaque.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 23, p. 191. (F. H. & H., 1900.)

2522. PATIENCE AND EXACTNESS OF SCIENCE—Through the precautions, variations, and repetitions observed and executed with the view of rendering its results secure, the separate vessels employed in this inquiry [as to spontaneous generation] ha-- mounted up in two years to

nearly ten thousand.—TYNDALL *Floating Matter of the Air,* essay 3, p. 318. (A., 1895.)

2523. ——— ——— *Calculation of Time of Halley's Comet.*—Halley calculated, with great pains, that the influence of the planets would delay the next return of the comet, and he predicted it for the end of 1758 or the beginning of 1759. It was necessary, with the improved mathematical formulæ, to calculate exactly the epoch of this return. Clairaut undertook this, and performed in a masterly manner the algebraical part of the problem; but there remained the immense task of calculating the formulæ numerically. Two computers had the courage to do this—the astronomer Lalande and Madame Hortense Lepaute. During six months the two calculators, hardly taking time to eat, put into numbers the algebraical formulæ of Clairaut. Lalande finished the calculation, and found that Saturn would delay its return by 100 days and Jupiter by 518 days, in all 618 days' delay—that is to say, that its revolution would be a year and eight months longer than its previous revolution; and that, in fact, its perihelion passage would take place within a month of the middle of April, 1759.

Never did scientific prediction excite more lively curiosity from one end of Europe to the other. *The comet reappeared;* it traversed the course announced among the constellations; it passed its perihelion on March 12, 1759, just a month before the day indicated. "We have all observed it," wrote Lalande, "so that it is beyond doubt that comets are truly planets which revolve, like the others, round the sun." Halley's comet, in fulfilling the prediction of the astronomers, opened a new era in cometary astronomy.—FLAMMARION *Popular Astronomy,* bk. v, ch. 1, p. 486. (A.)

2524. ——— ——— *Identification of the Metals of the Sun.*—There have been identified, line for line, in the sun the 460 lines of the spectrum of iron, the 118 of titanium, 75 of calcium, 57 of manganese, 33 of nickel, etc., so that we now know certainly that there are at the surface of that dazzling star, and in the gaseous state, iron, titanium, calcium, manganese, nickel, cobalt, chromium, sodium, barium, magnesium, copper, potassium; but we still cannot recognize any trace of gold, silver, antimony, arsenic, or mercury. Hydrogen was discovered in 1868. Oxygen must exist in this furnace, but the oxygen lines which have been found in the solar spectrum proceed from our own atmosphere (Janssen, 1888).—FLAMMARION *Popular Astronomy,* bk. iii, ch. 7, p. 326. (A.)

2525. ——— ——— *Minute Adjustments—Delicacy of Eye and Hand.*—Nine years later Dr. Henry Draper, of New York, got an impression of four lines in the spectrum of Vega. Then Dr. Huggins attacked the subject again in 1876, when the 18-inch speculum of the Royal Society had come into his possession, using prisms of Iceland spar and lenses of quartz, and this time with better success. A photograph of the spectrum of Vega showed seven strong lines. Still he was not satisfied. He waited and worked for three years longer. At length, on December 18, 1879, he was able to communicate with the Royal Society results answering to his expectations. The delicacy of eye and hand needed to attain them may be estimated from the single fact that the image of a star had to be kept, by continual minute adjustments, exactly projected upon a slit $\frac{1}{250}$ of an inch in width during nearly an hour, in order to give it time to imprint the characters of its analyzed light upon a gelatin plate raised to the highest pitch of sensitiveness.—CLERKE *History of Astronomy,* pt. ii, ch. 12, p. 462. (Bl., 1893.)

2526. ——— ——— *Tracing Gradations of Species.*—For five consecutive years I have investigated this small but highly instructive group of animals [the calcareous sponges] in all its forms in the most careful manner. . . . With a view to these facts, I made two journeys to the seacoast (1869 to Norway, 1871 to Dalmatia), in order to study as large a number of individuals as possible in their natural circumstances, and to collect specimens for comparison. Of many species I compared several hundred individuals in the most careful way. I examined with the microscope and measured in the most accurate manner the details of form of all the species. As the final result of these exhaustive and almost endless examinations and measurements it appeared that "good species," in the ordinary dogmatic sense of the systematists, have no existence at all among the calcareous sponges; that the most different forms are connected one with another by numberless gradational transition forms; and that all the different species of calcareous sponges are derived from a single exceedingly simple ancestral form, the olynthus.—HAECKEL *History of Creation,* vol. i, pref., p. 17. (K. P. & Co., 1899.)

2527. PATIENCE OF ASTRONOMER—*Vast Endeavor for Limited Result—Five Minutes' Observation the Reward of a Day's Watching.*—The surface of the sun may be compared to an elaborate engraving, filled with the closest and most delicate lines and hatchings, but an engraving which during ninety-nine hundredths of the time can only be seen across such a quivering mass of heated air as makes everything confused and liable to be mistaken, causing what is definite to look like a vaguely seen mottling. It is literally true that the more delicate features . . . are only distinctly visible even by the best telescope during less than one-hundredth of the time, coming out as they do in brief instants when our dancing air is momentarily still, so that one who has

sat at a powerful telescope all day is exceptionally lucky if he has secured enough glimpses of the true structure to aggregate five minutes of clear seeing, while at all other times the attempt to magnify only produces a blurring of the image. This study, then, demands not only fine telescopes and special optical aids, but endless patience.—LANGLEY *New Astronomy,* ch. 1, p. 17. (H. M. & Co., 1896.)

2528. PEACE, WOMAN'S INFLUENCE FOR—A charming confession is made by [E. H. Man] with reference to the moral influence of woman's presence. He says: "Experience has taught us that one of the most effective means of inspiring confidence when endeavoring to make acquaintance with these savages is to show that we are accompanied by women, as they at once infer that, whatever may be our intentions, they are at least not hostile."—MASON *Woman's Share in Primitive Culture,* int., p. 7. (A., 1894.)

2529. PEAKS, VOLCANIC, THE WORK OF TIME—*The Slow Building of Mountains.*—All volcanic mountains are nothing but heaps of materials ejected from fissures in the earth's crust, the smaller ones having been formed during a single volcanic outburst, the larger ones being the result of repeated eruptions from the same orifice, which may, in some cases, have continued in action for tens or hundreds of thousands of years.—JUDD *Volcanoes,* ch. 4, p. 75. (A., 1899.)

2530. PECULIARITIES OF GEOGRAPHIC DISTRIBUTION—*Humming-birds Confined to the American Continent.*—We come on the curious facts of geographical distribution, a class of facts which, as much as any other, suggest some specific methods as having been followed in the work of creation. Humming-birds are absolutely confined to the great continent of America, with its adjacent islands. Within those limits there is every range of climate, and there are particular species of humming-bird adapted to every region where a flowering vegetation can subsist. It is therefore neither climate nor food which confines the humming-birds to the New World. What is it, then? The idea of "centers of creation" is at once suggested to the mind. It seems as if the humming-birds were introduced at one spot, and as if they had spread over the whole continent which was accessible to them from that spot. They are absent elsewhere, simply because from that spot the other continents of the world were inaccessible to them.—ARGYLL *Reign of Law,* ch. 5, p. 133. (Burt.)

2531. PENALTY OF DISUSE—*Eyes of Cave-fish Atrophied.*—For instance, if a species which had always lived in the light were to find its way into some new habitat where there was complete darkness, its eyes would become useless to it; and accordingly we commonly find that in such species the eyes have more or less completely atrophied.

This is the case, for instance, with animals which live in dark caves. . . . In the Mammoth Cave of Kentucky, among other blind animals we find a blind fish and a blind fresh-water crayfish. It is almost superfluous to offer any further proof that these species are descended from ancestors which possessed the power of sight beyond the fact that the caverns in question have not existed from the beginnings of organic life, and that therefore the animals must have lived in the light before they entered them. Nevertheless, in many of these animals direct proof exists in the fact that they still possess vestiges of what have once been eyes. The proteus and the blind fish of the Mammoth Cave have small, imperfectly developed eyes under the skin, which are no longer of any use as organs of sight. In the case of the blind crayfish the eyes have entirely disappeared, altho the movable stalks upon which they were placed still remain.—WEISMANN *Heredity,* vol. ii, ch. 9, p. 9. (Cl. P., 1897.)

2532. PENDULUM TELLS FORM OF EARTH—*Galileo and the Chandeliers.*—Galileo, who first observed when a boy (having, probably, suffered his thoughts to wander from the service) that the height of the vaulted roof of a church might be measured by the time of the vibration of the chandeliers suspended at different altitudes, could hardly have anticipated that the pendulum would one day be carried from pole to pole, in order to determine the form of the earth.—HUMBOLDT *Cosmos,* vol. i, p. 167. (H., 1897.)

2533. PENETRATION AND ACUTENESS OF A GREAT MIND—*Scientific Spirit of Columbus.*—Among the characteristics of Christopher Columbus we must especially notice the penetration and acuteness with which, without intellectual culture, and without any knowledge of physical and natural science, he could seize and combine the phenomena of the external world. On his arrival in a new world and under a new heaven he examined with care the form of continental masses, the physiognomy of vegetation, the habits of animals, and the distribution of heat and the variations in terrestrial magnetism. While the old admiral strove to discover the spices of India, and the rhubarb *(ruibarba),* which had already acquired a great celebrity through the Arabian and Jewish physicians, and through the account of Rubruquis and the Italian travelers, he also examined with the greatest attention the roots, fruits, and leaves of the different plants. . . . In the journal of his voyage and in his reports . . . we find almost all those circumstances touched upon to which scientific enterprise was directed in the latter half of the fifteenth and throughout the

whole of the sixteenth centuries.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 263. (H., 1897.)

2534. PENETRATION OF LIGHT THROUGH WATER—*No Sunlight in Ocean Depths.*—The entire absence of solar light, which constitutes another most important peculiarity in the conditions of deep-sea life, would seem at first sight to be an absolute bar to its maintenance. Experimental evidence has not yet, I believe, been obtained of the direct penetration of the solar rays to more than 100 fathoms; but as I dredged slow-growing red calcareous algæ (true corallines) in the Mediterranean at a depth of 150 fathoms (at or below which Edward Forbes also would seem to have met with them), the actinic, if not the luminous, rays must probably penetrate to that range. Below what Edward Forbes termed the coralline zone it would seem impossible that any other type of vegetable life can be sustained than such as has the capacity of the fungi for growing in the dark, living, like them, upon material supplied by the decomposition of organic compounds. Such lowly plants have been found by Professor P. M. Duncan in corals dredged from more than 1,000 fathoms' depth.—CARPENTER *Nature and Man*, lect. 11, p. 345. (A., 1889.)

2535. PENTATEUCH IN HARMONY WITH ARCHEOLOGY — *Bronze before Iron —Progress from the Ductile to the Stubborn Metal.*—The forms of early weapons indicate that those of iron were copied from bronze, not those of bronze from iron. Hesiod's poems, as well as those of Homer, show that nearly three thousand years ago the value of iron was known and appreciated. It is true that, as we read in Dr. Smith's "Dictionary of Greek and Roman Antiquities," bronze "is represented in the "Iliad" and "Odyssey" as the common material of arms, instruments, and vessels of various sorts; the latter (iron) is mentioned much more rarely." While, however, the above statement is strictly correct, we must remember that among the Greeks the word iron (σίδηρος) was used, even in the time of Homer, as synonymous with a sword, and that steel also appears to have been known to them under the name of ἀδάμας, and perhaps also of κύανος, as early as the time of Hesiod. We may, therefore, consider that the Trojan war took place during the period of transition from the Bronze to the Iron Age.

In the Pentateuch, including Deuteronomy, bronze, or, as it is unfortunately translated, "brass," is mentioned thirty-eight times, and iron only four times.—AVEBURY *Prehistoric Times*, ch. 1, p. 5. (A., 1900.)

2536. "PEPPER-POT" OF TROPICAL AMERICA—*An Invention of Woman.*—The Indian women of Guiana are excellent purveyors. They have but one way of cooking meat or fish, and that is by boiling it down into a sort of thick soup, with peppers and cassareep, or the juice of strained cassava boiled down to a sirup. The cassareep reduces all meat to one common flavor—its own—and has antiseptic qualities which keep meat boiled in it good for a long time. The result is the far-famed pepper-pot, which all settlers in the West Indies have learned to make and to like.—MASON *Woman's Share in Primitive Culture*, ch. 2, p. 38. (A., 1894.)

2537. PERCEPTION INCREASED BY HABITUAL ATTENTION — *Deaf-and-dumb Lip-reading.*—It has long been known that individuals among the deaf and dumb have acquired the power of "lip-reading"; that is, of so interpreting the visible movements of the mouth and lips of a speaker as to apprehend the words he utters, no less accurately than if they were heard. And it has been latterly proposed to make this a matter of systematic instruction, so that every deaf-mute should be enabled to understand what is said, without the aid of the "sign-language" or the "finger-alphabet." It appears, however, that it is not every one who is capable of acquiring this power, and it is still questionable whether it can be even generally attained by any amount of practise. [It has been done on a considerable scale.] But that it should have been even exceptionally acquired shows the extraordinary improvability of the perceptive faculty.—CARPENTER *Mental Physiology*, bk. i, ch. 5, p. 204. (A., 1900.)

2538. PERCEPTION, JUDGMENT, AND PERSEVERANCE NEEDED FOR SUCCESSFUL SELECTION—*Accumulation of Almost Imperceptible Differences.*—When a cross [in breeding] has been made, the closest selection is far more indispensable even than in ordinary cases. If selection consisted merely in separating some very distinct variety and breeding from it, the principle would be so obvious as hardly to be worth notice; but its importance consists in the great effect produced by the accumulation in one direction, during successive generations, of differences absolutely inappreciable by an uneducated eye—differences which I for one have vainly attempted to appreciate. Not one man in a thousand has accuracy of eye and judgment sufficient to become an eminent breeder. If gifted with these qualities, and he studies his subject for years, and devotes his lifetime to it with indomitable perseverance, he will succeed, and may make great improvements; if he wants any of these qualities, he will assuredly fail. Few would readily believe in the natural capacity and years of practise requisite to become even a skilful pigeon-fancier.—DARWIN *Origin of Species*, ch. 1, p. 27. (Burt.)

2539. PERCEPTION LARGELY PSYCHIC—*We See What We Know or Believe To Be.*—The grass out of the window now looks to me of the same green in the sun as in the shade, and yet a painter would have to

paint one part of it dark brown, another part bright yellow, to give its real sensational effect. We take no heed, as a rule, of the different way in which the same things look and sound and smell at different distances and under different circumstances. The sameness of the things is what we are concerned to ascertain, and any sensations that assure us of that will probably be considered, in a rough way, to be the same with each other.—JAMES *Psychology*, vol. i, ch. 9, p. 231. (H. H. & Co., 1899.)

2540. PERCEPTION OF COLORS LIMITED—*Chemical or Ultraviolet Waves Invisible.*—The first question that we have to consider to-night is this: Is the eye, as an organ of vision, commensurate with the whole range of solar radiation—is it capable of receiving visual impressions from all the rays emitted by the sun? The answer is negative. If we allowed ourselves to accept for a moment that notion of gradual growth, amelioration, and ascension implied by the term "evolution," we might fairly conclude that there are stores of visual impressions awaiting man, far greater than those now in his possession. Ritter discovered in 1801 that beyond the extreme violet of the spectrum there is a vast efflux of rays which are totally useless as regards our present powers of vision. These ultraviolet waves, however, tho incompetent to awaken the optic nerve, can shake asunder the molecules of certain compound substances on which they impinge, thus producing chemical decomposition.—TYNDALL *Lectures on Light*, lect. 5, p. 162. (A., 1898.)

2541. PERCEPTION OF LIGHT IN PAINTING ILLUSIVE—*Relative Judgment of Light and Shade Determines Mental Effect.*—It is found that the degree of luminosity or brightness of a pictorial representation differs in general enormously from that of the actual objects. Thus, according to the calculations of Helmholtz, a picture representing a Bedouin's white raiment in blinding sunshine will, when seen in a fairly lit gallery, have a degree of luminosity reaching only to about one-thirtieth of that of the actual object. On the other hand, a painting representing marble ruins illuminated by moonlight will, under the same conditions of illumination, have a luminosity amounting to as much as from ten to twenty thousand times that of the object. Yet the spectator does not notice these stupendous discrepancies. The representation, in spite of its vast difference, at once carries the mind on to the actuality, and the spectator may even appear to himself, in moments of complete absorption, to be looking at the actual scene.—SULLY *Illusions*, ch. 5, p. 88. (A., 1897.)

2542. PERCEPTION OF TIME AND SPACE DISTURBED BY HASHISH—*Minutes Seem Hours—Distance Seems Interminable.*—The disturbance of the perceptive faculties [by hashish] is remarkably shown in regard to time and space. Minutes seem hours, and hours are prolonged into years; and at last all idea of time seems obliterated, and the past and present are confounded together. M. Moreau mentions as an illustration that on one evening he was traversing the passage of the opera when under the influence of a moderate dose of hashish: he had made but a few steps, when it seemed to him as if he had been there two or three hours; and, as he advanced, the passage appeared to him interminable, its extremity receding as he pressed forwards. But he gives another more remarkable instance. In walking along the boulevards, he has frequently seen persons and things at a certain distance presenting the same aspect as if he had viewed them through the large end of an opera-glass; that is, diminished in apparent size, and therefore suggesting the idea of increased distance. This erroneous perception of space is one of the effects of the *Amanita muscaria*, an intoxicating fungus used by the Tatars; a person under its influence being said to take a jump or a stride sufficient to clear the trunk of a tree, when he wishes only to step over a straw or a small stick. Such erroneous perceptions are common enough among lunatics, and become the foundations of fixed illusions; whilst in the person intoxicated by hashish there is still a certain consciousness of their deceptive character.—CARPENTER *Mental Physiology*, bk. ii, ch. 17, p. 642. (A., 1900.)

2543. PERCEPTION, POWER OF, AMONG SAVAGES—*Arab Knows Footprint of His Own Camels.*—In reading almost any account of savages it is impossible not to admire the skill with which they use their weapons and implements, their ingenuity in hunting and fishing, and their close and accurate powers of observation. Some savages even recognize individuals by their footsteps. Thus Mr. Laing mentions that one day while traveling near Moreton Bay, in Australia, he pointed to a footstep and asked whose it was. The guide "glanced at it without stopping his horse and at once answered, 'White fellow call him Tiger.'" This turned out to be correct, which was the more remarkable as the two men belonged to different tribes, and had not met for two years. Among the Arabs, Burckhardt asserts that some men know every individual in the tribe by his footstep. "Besides this, every Arab knows the printed footsteps of his own camels and of those belonging to his immediate neighbors. He knows by the depth or slightness of the impression whether a camel was pasturing and therefore not carrying any load, or mounted by one person only, or heavily loaded."—AVEBURY *Prehistoric Times*, ch. 15, p. 519. (A., 1900.)

2544. PERCEPTION RELATIVE—*Light and Dark Determined by Contrast.*—What appeals to our attention far more

than the absolute quality or quantity of a given sensation is its ratio to whatever other sensations we may have at the same time. When everything is dark, a somewhat less dark sensation makes us see an object white. Helmholtz calculates that the white marble painted in a picture representing an architectural view by moonlight is, when seen by daylight, from ten to twenty thousand times brighter than the real moonlit marble would be.—JAMES *Psychology*, vol. i, ch. 9, p. 231. (H. H. & Co., 1899.)

2545. PERFECTION, MATHEMATICAL, OF HONEY-BEE'S CELL—[As stated by Dr. Reid] there are only three possible figures of the cells which can make them all equal and similar, without any useless interstices. These are the equilateral triangle, the square, and the regular hexagon. Mathematicians know that there is not a fourth way possible in which a plane may be cut into little spaces that shall be equal, similar, and regular, without useless spaces. Of the three figures, the hexagon is the most proper for convenience and strength. Bees, as if they knew this, make their cells regular hexagons.

Again, it has been demonstrated that, by making the bottoms of the cells to consist of three planes meeting in a point, there is a saving of material and labor in no way inconsiderable. The bees, as if acquainted with these principles of solid geometry, follow them most accurately. It is a curious mathematical problem, at what precise angle the three planes which compose the bottom of a cell ought to meet, in order to make the greatest possible saving or the least expense of material and labor. This is one of the problems which belong to the higher parts of mathematics. It has accordingly been resolved by some mathematicians, particularly by the ingenious Maclaurin, by a fluctionary calculation, which is to be found in the *Transactions* of the Royal Society of London. He has determined precisely the angle required, and he found, by the most exact mensuration the subject would admit, that it is the very angle in which the three planes in the bottom of the cell of a honeycomb do actually meet.—ROMANES *Animal Intelligence*, ch. 4, p. 171. (A., 1899.)

2546. PERFECTION, MECHANICAL, OF INSECT'S WORK—*Larva Spinning Its Shroud.*—For some time Mr. Agassiz has been trying to get living specimens of the insect so injurious to the coffee-tree, the larva of a little moth akin to those which destroy the vineyards in Europe. Yesterday he succeeded in obtaining some, and among them one just spinning his cocoon on the leaf. We watched him for a long time with the lens as he wove his filmy tent. He had arched the threads upwards in the center, so as to leave a little hollow space into which he could withdraw; this tiny vault seemed to be completed at the moment we saw him, and he was drawing threads forward and fastening them at a short distance beyond, thus lashing his house to the leaf, as it were. The exquisite accuracy of the work was amazing. He was spinning the thread with his mouth, and with every new stitch he turned his body backward, attached his thread to the same spot, then drew it forward and fastened it exactly on a line with the last, with a precision and rapidity that machinery could hardly imitate.—AGASSIZ *Journey in Brazil (extract from Journal of Mrs. Agassiz)*, ch. 3, p. 117. (H. M. & Co., 1896.)

2547. PERFECTION OF APPARATUS, IMPORTANCE OF—*Velocity of Light—Error as to Sun's Distance Vitiated Early Measurements—A Terrestrial Distance, That Can Be Surely Measured, Now Made the Basis of Calculation.*—Fizeau, and quite recently Cornu, employing not planetary or stellar distances, but simply the breadth of the city of Paris, determined the velocity of light: while Foucault—a man of the rarest mechanical genius—solved the problem without quitting his private room. Owing to an error in the determination of the earth's distance from the sun, the velocity [192,500 miles per second] assigned to light by both Römer and Bradley is too great. With a close approximation to accuracy it may be regarded as 186,000 miles a second. [From a discussion of all observations in 1891, Professor Harkness found 186,337 $\pm$ 49.722 miles (J. E. Gore, in Flammarion's "Popular Astronomy," p. 318). Flammarion takes 300,000 kilometers, or 186,414 miles, as an accurate statement "in round numbers."]—TYNDALL *Lectures on Light*, lect. 1, p. 23. (A., 1898.)

2548. PERFECTION OF EARLY INSTINCT—*Common Spiders.*—Mr. Blackwall, speaking of British spiders, says: "Complicated as the processes are by which these symmetrical nets are produced, nevertheless young spiders, acting under the influence of instinctive impulse, display, even in their first attempts to fabricate them, as consummate skill as the most experienced individuals."—ROMANES *Animal Intelligence*, ch. 6, p. 216. (A., 1899.)

2549. ——— ——— *Trap-door Spiders.*—Speaking of trap-door spiders, Moggridge says:

"I cannot help thinking that these very small nests, built as they are by minute spiders probably not very long hatched from the egg, must rank among the most marvelous structures of this kind with which we are acquainted. That so young and weak a creature should be able to excavate a tube in the earth many times its own length, and know how to make a perfect miniature of the nest of its parents, seems to be a fact which has scarcely a parallel in Nature."—ROMANES *Animal Intelligence*, ch. 6, p. 217. (A., 1899.)

2550. ——— ——— *Veteran Hunter Foiled by Newly Hatched Bird.*—On a secluded lake in one of the Hebrides I observed a dun diver, or female of the red-breasted merganser *(Mergus serrator)*, with her brood of young ducklings. On giving chase in the boat, we soon found that the young, altho not above a fortnight old, had such extraordinary powers of swimming and diving that it was almost impossible to capture them. The distance they went under water, and the unexpected places in which they emerged, baffled all our efforts for a considerable time. At last one of the brood made for the shore, with the object of hiding among the grass and heather which fringed the margin of the lake. We pursued it as closely as we could, but when the little bird gained the shore our boat was still about twenty yards off. Long drought had left a broad margin of small flat stones and mud between the water and the usual bank. I saw the little bird run up about a couple of yards from the water, and then suddenly disappear. Knowing what was likely to be enacted, I kept my eye fixed on the spot, and when the boat was run upon the beach I proceeded to find and pick up the chick. But on reaching the place of disappearance, no sign of the young merganser was to be seen. The closest scrutiny, with the certain knowledge that it was there, failed to enable me to detect it. Proceeding cautiously forwards, I soon became convinced that I had already overshot the mark; and, on turning round, it was only to see the chick rise like an apparition from the stones, and, dashing past the stranded boat, regain the lake, where, having now recovered its wind, it instantly dived and disappeared. The tactical skill of the whole of this maneuver, and the success with which it was executed, were greeted with loud cheers from the whole party, and our admiration was not diminished when we remembered that some two weeks before that time the little performer had been coiled up inside the shell of an egg, and that about a month before it was apparently nothing but a mass of albumen and of fatty oils.—ARGYLL *Unity of Nature*, ch. 3, p. 50. (Burt.)

2551. PERFECTION OF MAN AS MAN—*Liberal vs. Professional Education—Bread-and-butter Sciences.*—Now, the perfection of man as an end, and the perfection of man as a mean or instrument, are not only not the same; they are, in reality, generally opposed. And as these two perfections are different, so the training requisite for their acquisition is not identical, and has, accordingly, been distinguished by different names. The one is styled liberal, the other professional, education; the branches of knowledge cultivated for these purposes being called, respectively, liberal and professional, or liberal and lucrative, sciences. By the Germans the latter are usually distinguished as the *Brodwissenschaften*, which we may translate the "Bread-and-butter sciences." A few of the professions, indeed, as requiring a higher development of the higher faculties, and involving, therefore, a greater or less amount of liberal education, have obtained the name of liberal professions. We must, however, recollect that this is only an accidental and a very partial exception. But tho the full and harmonious development of our faculties be the high and natural destination of all, while the cultivation of any professional dexterity is only a contingency, tho a contingency incumbent upon most, it has, however, happened that the paramount and universal end of man—of man absolutely—has been often ignorantly lost sight of, and the term "useful" appropriated exclusively to those acquirements which have a value only to man considered in his relative, lower, and accidental character of an instrument.—HAMILTON *Metaphysics*, lect. 1, p. 4. (G. & L., 1859.)

2552. PERFECTION OF MAN THE GOAL OF NATURE—*Evolution Exalts Humanity.*—To pursue unflinchingly the methods of science requires dauntless courage and a faith that nothing can shake. Such courage and such loyalty to Nature bring their own reward. For when once the formidable theory [of natural selection] is really understood, when once its implications are properly unfolded, it is seen to have no such logical consequences as were at first ascribed to it. As with the Copernican astronomy, so with the Darwinian biology, we rise to a higher view of the workings of God and of the nature of man than was ever attainable before. So far from degrading humanity, or putting it on a level with the animal world in general, the Darwinian theory shows us distinctly for the first time how the creation and the perfecting of man is the goal toward which Nature's work has all the while been tending. It enlarges tenfold the significance of human life, places it upon even a loftier eminence than poets or prophets have imagined, and makes it seem more than ever the chief object of that creative activity which is manifested in the physical universe.—FISKE *Destiny of Man*, ch. 2, p. 24. (H. M. & Co., 1900.)

2553. PERFECTION OF THE GEOLOGICAL RECORD—*Life History of the Trilobite in Stone.*—Their [the trilobites'] geological history has been very thoroughly studied; not only are we familiar with all their adult characters, but even their embryology is well known to naturalists. It is, indeed, wonderful that the mode of growth of animals which died out in the Carboniferous period should be better known to us than that of many living types. But it is nevertheless true that their embryonic forms have been found perfectly preserved in the rocks. . . . So complete is the sequence that the plate on which their em-

bryonic changes are illustrated contains more than thirty figures, all representing different phases of their growth. There is not a living crab represented so fully in any of our scientific works as is that one species of trilobite whose whole story Barrande has traced from the egg to its adult size.—AGASSIZ *Geological Sketches*, ser. i, ch. 2, p. 53. (H. M. & Co., 1896.)

2554. PERFECTION SHEDS LIGHT ON IMPERFECTION — *Complete Specimens Give Meaning to Fragments.*—But cases, tho few and rare, do occur in which, through some favorable accident connected with the death or sepulture of some individual existence of the period, its remains have been preserved almost entire; and one such specimen serves to throw light on whole heaps of the broken remains of its contemporaries. The single elephant, preserved in an iceberg beside the Arctic Ocean, illustrated the peculiarities of the numerous extinct family to which it belonged, whose bones and huge tusks whiten the wastes of Siberia. The human body found in an Irish bog, with the ancient sandals of the country still attached to its feet by thongs, and clothed in a garment of coarse hair, gave evidence that bore generally on the degree of civilization attained by the inhabitants of an entire district in a remote age. In all such instances the character and appearance of the individual bear on those of the tribe. In attempting to describe the organisms of the lower old red sandstone, where the fossils lie as thickly in some localities as herrings on our coasts in the fishing season, I felt as if I had whole tribes before me.—MILLER *The Old Red Sandstone*, ch. 9, p. 152. (G. & L., 1851.)

2555. PERIL DEFIED OR IGNORED —"*Sporting on the Volcano's Edge*"—*Prosperity and Happiness in the Endangered Lands.*—The first impression which is produced upon the mind, when the phenomena of volcanic action are studied, is that here we have exhibitions of destructive violence the effects of which must be entirely mischievous and disastrous to the living beings occupying the earth's surface. A little consideration will convince us, however, that the grand and terrible character of the displays of volcanic energy have given rise to exaggerated notions concerning their destructive effects. The fact that districts situated over the most powerful volcanic foci, like Java and Japan, are luxuriant in their productions, and thickly inhabited, may well lead us to pause ere we condemn volcanic action as productive only of mischief to the living beings on the earth's surface. The actual slopes of Vesuvius and Etna, and many other active volcanoes, are abundantly clothed with vineyards and forests, and are thickly studded with populous villages.—JUDD *Volcanoes*, ch. 10, p. 281. (A., 1899.)

2556. PERIL, FICTITIOUS—*No Lions in the Deserts—Vipers and Mosquitoes the Real Terrors.*—Of larger wild animals, only gazelles, wild asses, and ostriches are to be met with [in the Desert of Sahara]. "That lions exist in the desert," says M. Carette ["Exploration Scientif. de l'Algérie," t. ii, p. 332], "is a myth popularized by the dreams of artists and poets, and has no foundation but in their imagination. This animal does not quit the mountains, where it finds shelter, food, and drink. When the traveler questions the natives concerning these wild beasts, which Europeans suppose to be their companions in the desert, they reply, with imperturbable *sang-froid*, 'Have you, then, lions in your country which can drink air and eat leaves? With us, lions require running water and living flesh; and therefore they only appear where there are wooded hills and water. We fear only the viper *(lefa)*, and, in humid spots, the innumerable swarms of mosquitoes which abound there.'"—HUMBOLDT *Views of Nature*, p. 90. (Bell, 1896.)

2557. PERIL IN EXALTATION—*In Earthquake Countries, Lowliness Is Safety—Spaniards "Building Their Own Sepulchers."*—Another plan adopted in South America can be gathered from the same author's [James Douglas, in his "Journey along the West Coast of South America"] writings upon Lima, about which he says: "To build high houses would be to erect structures for the first earthquake to make sport of, and, therefore, in order to obtain space, safety, and comfort, the houses of the wealthy surround court after court, filled with flowers and cooled with fountains, connected one with another with wide passages which give a vista from garden to garden."

History would indicate that houses of this type have been arrived at as the results of experience, for it is said that when the inhabitants of South America first saw the Spaniards building tall houses they told them they were building their own sepulchers.

In Jamaica we find that even as early as 1692 experience had taught the Spaniards to construct low houses, which withstood shakings better than the tall ones.—MILNE *Earthquakes*, ch. 7, p. 127. (A., 1899.)

2558. PERIL UNIMAGINED—*A Slumbering Volcano—Vesuvius before the Eruption of A. D. 79—Its Slopes Vineyards—Its Crater a Fortress.*—Nothing is more certain than the fact that the Vesuvius upon which the ancient Romans and the Greek settlers of southern Italy looked, was a mountain differing entirely in its form and appearance from that with which we are familiar. The Vesuvius known to the ancients was a great truncated cone, having a diameter at its base of eight or nine miles, and a height of about 4,000 feet. The summit of this mountain was formed by a circular depressed plain, nearly three miles in diam-

eter, within which the gladiator Spartacus and his followers were besieged by a Roman army. There is no evidence that at this time the volcanic character of the mountain was generally recognized, and its slopes are described by the ancient geographers as being clothed with fertile fields and vineyards, while the hollow at the top was a waste overgrown with wild vines.

But in the year 79 a terrible and unexpected eruption occurred, by which . . . the cities of Pompeii, Herculaneum, and Stabiæ were overwhelmed and buried.—JUDD *Volcanoes*, ch. 4, p. 83. (A., 1899.)

2559. PERILS OF THE SNOW—*Traveler's Sense of Direction Destroyed by Swirling Eddies.*—Snow is not always our friend. . . . In thinly inhabited countries there is no greater danger than to be overtaken by a heavy fall of snow or caught in storms of snow-dust, raised from ground on which snow has previously fallen and whirled along by the wind. In such cases one's only safety is to make at once for the nearest human dwelling in sight. If there is none in sight, the danger of being lost is great, for nothing so destroys one's sense of direction as the confused eddies of falling snow or swirling snow-dust.—CHISHOLM *Nature-Studies*, p. 31. (Hum., 1888.)

2560. PERMANENCE, APPARENT—*Mountain Seems Eternal—A First View of the Matterhorn.*—Above us rise the towers and pinnacles of the Matterhorn, certainly a tremendous array. Actual contact immensely increases one's impressions of this, the hardest and strongest of all the mountain masses of the Alps; its form is more remarkable than that of other mountains, not by chance, but because it is built of more massive and durable materials, and more solidly put together: nowhere have I seen such astonishing masonry. The broad gneiss blocks are generally smooth and compact, with little appearance of splintering or weathering. Tons of rock, in the shape of boulders, must fall almost daily down its sides, but the amount of these, even in the course of centuries, is as nothing compared with the mass of the mountain; the ordinary processes of disintegration can have little or no effect on it. If one were to follow Mr. Ruskin, in speculating on the manner in which the Alpine peaks can have assumed their present shape, it seems as if such a mass as this can have been blocked out only while rising from the sea, under the action of waves such as beat against the granite headlands of the Land's End. Once on dry land it must stand as it does now, apparently forever.—HAWKINS in TYNDALL'S *Hours of Exercise in the Alps*, ch. 3, p. 39. (A., 1898.)

2561. ——— ——— *Transition Unperceived—Changing Cloud on Mountain Peak.*—You frequently see a streamer of cloud many hundred yards in length drawn out from an Alpine peak. Its steadiness appears perfect, tho a strong wind may be blowing at the same time over the mountain-head. Why is the cloud not blown away? It is blown away; its permanence is only apparent. At one end it is incessantly dissolved, at the other end it is incessantly renewed: supply and consumption being thus equalized, the cloud appears as changeless as the mountain to which it seems to cling. When the red sun of the evening shines upon these cloud streamers they resemble vast torches with their flames blown through the air.—TYNDALL *Forms of Water*, p. 29. (A., 1899.)

2562. PERMANENCE OF CONCEPTIONS—*Change of Conceptions Is Not Alteration, but Substitution.*—Each conception thus eternally remains what it is, and never can become another. The mind may change its states and its meanings at different times, may drop one conception and take up another, but the dropped conception can in no intelligible sense be said to change into its successor. The paper, a moment ago white, I may now see to have been scorched black. But my conception "white" does not change into my conception "black." On the contrary, it stays alongside of the objective blackness, as a different meaning in my mind, and by so doing lets me judge the blackness as the paper's change. Unless it stayed, I should simply say "blackness" and know no more. Thus, amid the flux of opinions and of physical things, the world of conceptions, or things intended to be thought about, stands stiff and immutable, like Plato's "Realm of Ideas."—JAMES *Psychology*, vol. i, ch. 12, p. 432. (H. H. & Co., 1899.)

2563. PERMANENCE OF LEVEL OF SWISS LAKES — *Extends at Least to the Bronze Age.*—As piles [in the remains of Swiss lake-dwellings] of the Bronze Age are sometimes found at a depth of as much as fifteen feet, and as it is manifest that buildings cannot have been constructed over water much deeper than this, it is evident that the Swiss lakes cannot then have stood at a much higher level than at present. This conclusion is confirmed by the position of Roman remains at Thonon, on the Lake of Geneva, and we thus obtain satisfactory evidence that the height of the Swiss lakes must have remained almost unaltered for a very long period.—AVEBURY *Prehistoric Times*, ch. 6, p. 176. (A., 1900.)

2564. PERPLEXITIES OF ETYMOLOGY—*Children Generalize from Different Starting-points—"Moon" and "Star"—So the Savage Children of the World.*—Examples of generalization among children abound in every nursery. A child is taken to the window by his nurse to see the moon. The easy monosyllable is caught up at once, and for some time the child applies it indiscriminately to anything bright or shining—the gas, the candle, the firelight are each "the moon." Mr. Romanes records a case where a

child made a similar use of the word "star" —the gas, the candle, the firelight were each "a star." If the makers of language proceeded on this principle, no wonder the philologist has riddles to read. How often must the savage children of the world have started off naming things from two such different points! — DRUMMOND *Ascent of Man*, ch. 5, p. 171. (J. P., 1900.)

2565. PERSEVERANCE OF INVENTOR — *Courage of Conviction — Self-sacrificing Enthusiasm.*—Somewhere about the time that Herschel set about polishing his first speculum, Pierre Louis Guinand, a Swiss artisan living near Chaux-de-Fonds, in the canton of Neuchâtel, began to grind spectacles for his own use, and was thence led on to the rude construction of telescopes by fixing lenses in pasteboard tubes. The sight of an English achromatic, however, stirred a higher ambition, and he took the first opportunity of procuring some flint-glass from England (then the only source of supply), with the design of imitating an instrument the full capabilities of which he was destined to be the humble means of developing. The English glass proving of inferior quality, he conceived the possibility, unaided and ignorant of the art as he was, of himself making better, and spent seven years (1784-90) in fruitless experiments directed to that end. Failure only stimulated him to enlarge their scale. He bought some land near Les Brenets, constructed upon it a furnace capable of melting two quintals of glass, and reducing himself and his family to the barest necessaries of life, he poured his earnings (he at this time made bells for repeaters) unstintingly into his crucibles. His undaunted resolution triumphed. In 1799 he carried to Paris and there showed to Lalande several disks of flawless crystal four to six inches in diameter. Lalande advised him to keep his secret, but in 1805 he was induced to remove to Munich, where he became the instructor of the immortal Fraunhofer. His return to Les Brenets in 1814 was signalized by the discovery of an ingenious mode of removing striated portions of glass by breaking and re-soldering the product of each melting, and he eventually attained to the manufacture of perfect disks up to 18 inches in diameter. An object-glass for which he had furnished the material to Cauchoix, procured him, in 1823, a royal invitation to settle in Paris; but he was no longer equal to the change, and died at the scene of his labors February 13 following.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 142. (Bl., 1893.)

2566. PERSEVERANCE OF SCIENCE —The grand campaign [for world-wide observation of the transit of Venus, 1874] had come to nothing. Nevertheless, no sign of discouragement was apparent. There was a change of view, but no relaxation of purpose. The problem, it was seen, could be solved by no single heroic effort, but by the patient approximation of gradual improvements. Astronomers, accordingly, looked round for fresh means, or more refined expedients for applying those already known. A new phase of exertion was entered upon.—CLERKE *History of Astronomy*, pt. ii, ch. 6, p. 292. (Bl., 1893.)

2567. ——— ——— *Fossils Found after Ten Years' Search.*— Immediately above the conglomerate there is a hundred and fourteen feet more of coarse sandstone strata, of a reddish yellow hue, with occasionally a few pebbles enclosed, and then twenty-seven feet additional of limestone and stratified clay. There are no breaks, no faults, no thinning out of strata—all the beds lie parallel, showing regular deposition. I had passed over the section twenty times before, and had carefully examined the limestone and the clay, but in vain. On this occasion, however, I was more fortunate. I struck off a fragment. It contained a vegetable impression of the same character with those of the ichthyolite beds; and after an hour's diligent search, I had turned out from the heart of the stratum plates and scales enough to fill a shelf in a museum—the helmet-like snout of an *Osteolepis*, the thorn-like spine of a *Cheiracanthus*, and a *Coccosteus* well-nigh entire. I had at length, after a search of nearly ten years, found the true place of the ichthyolite bed.—MILLER *The Old Red Sandstone*, ch. 7, p. 121. (G. & L., 1851.)

2568. ——— ——— *Kepler and the Orbit of Mars.*—It was this great eccentricity [of the orbit of Mars] which led Kepler to discover the true form of the planetary orbits, till then considered as perfectly circular; he took no less than seventeen years of labor to attain it, and very often he despaired of success.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 4, p. 374. (A.)

2569. PERSISTENCE, GENUINE AND SPURIOUS — *Decision of Character.*—There is no more remarkable difference in human character than that between resolute and irresolute natures. . . . Whereas in the irresolute all decisions are provisional and liable to be reversed, in the resolute they are settled once for all and not disturbed again. Now into every one's deliberations the representation of one alternative will often enter with such sudden force as to carry the imagination with itself exclusively, and to produce an apparently settled decision in its own favor. These premature and spurious decisions are of course known to every one. They often seem ridiculous in the light of the considerations that succeed them. But it cannot be denied that in the resolute type of character the accident that one of them has once been made does afterwards enter as a motive additional to the more genuine reasons why it should not be revoked, or, if provisionally revoked, why it should be made again. How many of us persist in a precipitate course which,

but for a moment of heedlessness, we might never have entered upon, simply because we hate to "change our mind!"—JAMES *Psychology*, vol. ii, ch. 26, p. 530. (H. H. & Co., 1899.)

2570. PERSISTENCE OF A STRONG CURRENT IN ITS COURSE—*Rivers Saw Mountains Asunder.*—It is remarkable . . . how persistent are great rivers in maintaining their direction. When it has been once fairly established a large river may outlive many revolutions of the surface. River-valleys are not seldom older than the mountain ridges which they sometimes traverse; or, to put it in another way, new mountains may come into existence without deflecting the rivers across whose valleys they may seem at one time to have extended, for the rivers have simply sawed their way through the ridges as these were being gradually developed.—GEIKIE *Earth Sculpture*, ch. 3, p. 45. (G. P. P., 1898.)

2571. PERSONALITY AFFECTS SCIENTIFIC OBSERVATION—Every time that, in a given country, there is a change of observer we remark a sudden variation in the annual number of auroras. It is necessary, therefore, as far as possible, to collect the observations over a whole region, and not content ourselves with a single station, for it often happens that in two neighboring places an aurora will be noted in the one which is unperceived at the other by a less attentive observer.—ANGOT *Aurora Borealis*, ch. 5, p. 91. (A., 1897.)

2572. PERSONALITY AN INEVITABLE CONCEPTION—*Natural Agencies and Powers Personified.*—It is the simplest and most natural of all conceptions that the agency of which we are most conscious in ourselves is like the agency which works in the world around us. Even supposing this conception to be groundless, and that, as some now maintain, a more scientific investigation of natural agencies abolishes the conception of design or purpose, or of personal will being at all concerned therein—even supposing this, it is not the less true that the transfer of conceptions founded on our own consciousness of agency and of power within us to the agencies and powers around us, is a natural, if it be not indeed a necessary, conception. That it is a natural conception is proved by the fact that it has been, and still is, so widely prevalent, as well as by the fact that what is called the purely scientific conception of natural agencies is a modern conception, and one which is confessedly of difficult attainment. So difficult, indeed, is it to expel from the mind the conception of personality in or behind the agencies of Nature, that it may fairly be questioned whether it has ever been effectually done. Verbal devices for keeping the idea out of sight are indeed very common; but even these are not very successful. . . . Those naturalists and philosophers who are most opposed to all theological explanations or conceptions of natural forces do, nevertheless, habitually, in spite of themselves, have recourse to language which derives its whole form, as well as its whole intelligibility, from those elements of meaning which refer to the familiar operations of our own mind and will. The very phrase "natural selection" is one which likens the operations of Nature to the operations of a mind exercising the power of choice. The whole meaning of the phrase is to indicate how Nature attains certain ends which are like "selection."—ARGYLL *Unity of Nature*, ch. 11, p. 275. (Burt.)

2573. PERSONALITY A PRIMITIVE CONCEPTION—*Aryan Impersonations of Elementary Powers.*—From this evidence, as we find it in the facts reported respecting the earliest forms of Aryan speech, it seems certain that the most ancient conceptions of the energies of Nature were conceptions of personality. In that dim and far-off time, when our prehistoric ancestors were speaking in a language long anterior to the formation of the oldest Sanskrit, we are told that they called the sun the illuminator, or the warmer, or the nourisher; the moon, the measurer; the dawn, the awakener; the thunder, the roarer; the rain, the rainer; the fire, the quick-runner. We are told further that in these personifications the earliest Aryans did not imagine them as possessing the material or corporeal forms of humanity, but only that the activities they exhibited were most easily conceived as comparable with our own. Surely this is a fact which is worth volumes of speculation. What was most easy and most natural then must have been most easy and most natural from the beginning. With such a propensity in the earliest men of whom we have any authentic record to see personal agency in everything, and with the general impression of unity and subordination under one system which is suggested by all the phenomena of Nature, it does not seem very difficult to suppose that the fundamental conception of all religion may have been in the strictest sense primeval.—ARGYLL *Unity of Nature*, ch. 12, p. 304. (Burt.)

2574. PERSONALITY, DESTRUCTION OF—*Animal Made a True Automaton*—*Instinctless Condition of Brainless Pigeons.*—Schrader gives a striking account of the instinctless condition of his brainless pigeons, active as they were in the way of locomotion and voice. "The hemisphereless animal moves in a world of bodies which . . . are all of equal value for him. . . . He is, to use Goltz's apt expression, impersonal. . . . Every object is for him only a space-occupying mass; he turns out of his path for an ordinary pigeon no otherwise than for a stone. He may try to climb over both. All authors agree that they never found any difference, whether it was an inanimate body, a cat, a dog, or a bird of

prey which came in their pigeon's way. The creature knows neither friends nor enemies; in the thickest company it lives like a hermit.—JAMES *Psychology*, vol. i, ch. 2, p. 77. (H. H. & Co., 1899.)

2575. PERSONALITY EMBODIED—*The Secret of Idolatry.*—The universality of this tendency to connect some material objects with religious worship, and the immense variety of modes in which this tendency has been manifested, are facts which receive a full and adequate explanation in our natural disposition to conceive of all personal agencies as living in some form and in some place, or as having some other special connection with particular things in Nature. Nor is it difficult to understand how the embodiments, or the symbols, or the abodes, which may be imagined and devised by men, will vary according as their mental condition has been developed in a good or in a wrong direction. And as these imaginings and devices are never as we see them now among savages, the work of any one generation of men, but are the accumulated inheritance of many generations, all existing systems of worship among them must be regarded as presumably very wide departures from the conceptions which were primeval.—ARGYLL *Unity of Nature*, ch. 11, p. 283. (Burt.)

2576. PERSONALITY INDIVIDUAL AND INCOMMUNICABLE—*Limit to the Possibility of Human Sympathy—A Lesson of Charity.*—There is a something in the intimacy of a man's own experience which he cannot make to pass entire into the heart and mind even of his most familiar companion, and thus it is that he is so often defeated in his attempts to obtain a full and a cordial possession of his sympathy. He is mortified, and he wonders at the obtuseness of the people around him, and that, with every human being he addresses, justness of his complainings, nor to feel the point upon which turn the truth and the reason of his remonstrances, nor to give their interested attention to the case of his peculiarities and of his wrongs, nor to kindle, in generous resentment, along with him, when he starts the topic of his indignation. He does not reflect, all the while, that, with every human being he addresses, there is an inner man, which forms a theater of passions, and of interests as busy, as crowded, and as fitted as his own to engross the anxious and the exercised feelings of a heart, which can alone understand its own bitterness, and lay a correct estimate on the burden of its own visitations. Every man we meet carries about with him, in the unperceived solitude of his bosom, a little world of his own, and we are just as blind, and as insensible, and as dull, both of perception and of sympathy, about his engrossing objects as he is about ours; and, did we suffer this observation to have all its weight upon us, it might serve to make us more candid, and more considerate of others. It might serve to abate the monopolizing selfishness of our nature.—CHALMERS *Astronomical Discourses*, p. 42. (R. Ct., 1848.)

2577. PHANTOMS KNOWN AS ILLUSIONS—*Specters Haunting a Scholar.*—We knew a gentleman of strong mind, and a most accomplished scholar, who was for many years subject to such fantasms, some sufficiently grotesque, and he would occasionally laugh heartily at their antics. Sometimes it appeared as if they interrupted a conversation in which he was engaged; and then, if with his family or intimate friends, he would turn to empty space, and say, "I don't care a farthing for ye; ye amuse me greatly sometimes, but you are a bore just now." His spectra, when so addressed, would to his eye resume their antics, at which he would laugh, turn to his friend, and continue his conversation. In other respects he was perfectly healthy, his mind was of more than ordinary strength, and he would speak of his fantoms, and reason upon their appearance, being perfectly conscious that the whole was illusive. —CARPENTER *Mental Physiology*, bk. i, ch. 4, p. 167. (A., 1900.)

2578. PHANTOMS OF IMAGINATION—*The Illusions of Desire.*—Long before the discovery of the New World it was believed that new lands in the far West might be seen from the shores of the Canaries and the Azores. These illusive images were owing, not to any extraordinary refraction of the rays of light, but produced by an eager longing for the distant and the unattained. The philosophy of the Greeks, the physical views of the Middle Ages, and even those of a more recent period have been eminently imbued with the charm springing from similar illusive fantoms of the imagination. At the limits of circumscribed knowledge, as from some lofty island shore, the eye delights to penetrate to distant regions. The belief in the uncommon and the wonderful lends a definite outline to every manifestation of ideal creation; and the realm of fancy—a fairy-land of cosmological, geognostical, and magnetic visions—becomes thus involuntarily blended with the domain of reality.—HUMBOLDT *Cosmos*, vol. i, p. 81. (H., 1897.)

2579. PHENOMENA MANIFESTATIONS OF ONE OMNIPRESENT POWER—*Conservation of Energy.*—All those who have most carefully studied the subject have arrived at the same results. There is, therefore, every reason to believe that the principle we have been illustrating is universally true. Let us then embody it in a definite statement. *All natural phenomena are the manifestation of the same omnipresent energy, which is transferred from one portion of matter to another without loss.*

But if the principle as thus stated be accepted we cannot rest here, for it in-

volves this further conclusion, which, however marvelous, must be true: *The sum total of all the active and latent energies in the universe is constant and invariable.* In other words, power is as indestructible as matter.

This grand truth is generally called the law of conservation of energy, and if it cannot as yet be regarded as absolutely verified there can be no question that it stands on a better basis to-day than did the law of gravitation one hundred years ago.—COOKE *Religion and Chemistry,* ch. 10, p. 302. (A., 1897.)

2580. PHENOMENA, NATURAL, RANGED UNDER LAW—*Religious Phenomena Need Like Classification.*—The effect of the introduction of law among the scattered phenomena of Nature has simply been to make science, to transform knowledge into eternal truth. The same crystallizing touch is needed in religion. Can it be said that the phenomena of the spiritual world are other than scattered? Can we shut our eyes to the fact that the religious opinions of mankind are in a state of flux? And when we regard the uncertainty of current beliefs, the war of creeds, the havoc of inevitable as well as of idle doubt, the reluctant abandonment of early faith by those who would cherish it longer if they could, is it not plain that the one thing thinking men are waiting for is the introduction of law among the phenomena of the spiritual world? When that comes we shall offer to such men a truly scientific theology. And the reign of law will transform the whole spiritual world as it has already transformed the natural world.—DRUMMOND *Natural Law in the Spiritual World,* pref., p. 8. (H. Al.)

2581. PHENOMENA OF NATURE MISINTERPRETED—*Aurora Borealis Mistaken for Conflagration.*—Seneca ("Naturales Questiones," i, 14, 15) says: "Among these phenomena should be ranged those appearances as of the heavens on fire so often reported by historians; sometimes these fires are high enough to shine among the stars; at others, so low that they might be taken for the reflection of a distant burning homestead or city. This is what happened under Tiberius, when the cohorts hurried to the succor of the colony of Ostia, believing it to be on fire. During the greater part of the night the heaven appeared to be illuminated by a faint light resembling a thick smoke."—ANGOT *Aurora Borealis,* ch. 1, p. 5. (A., 1897.)

2582. PHENOMENA REDUCED TO LAW—*Divested of Superstition.*—It is no small gain to have established the fact that volcanic phenomena, divested of all those wonderful attributes with which superstition and the love of the marvelous have surrounded them, are operations of Nature obeying definite laws, which laws we may hope by careful observation and accurate reasoning to determine; and that the varied appearances, presented alike in the grandest and feeblest outbursts, can all be referred to one simple cause—namely, the escape, from the midst of masses of molten materials, of imprisoned steam or water-gas.—JUDD *Volcanoes,* ch. 2, p. 38. (A., 1899.)

2583. PHILOSOPHY, ENDLESS PROBLEM OF—*The Mystery of Evil.*—Well-nigh universally has philosophy proceeded upon the assumption, whether tacit or avowed, that pain and wrong are things hard to be reconciled with the theory that the world is created and ruled by a Being at once all-powerful and all-benevolent. Why does such a Being permit the misery that we behold encompassing us on every side? . . . If this question could be fairly answered, does it not seem as if the burden of life, which so often seems intolerable, would forthwith slip from our shoulders and leave us, like Bunyan's pilgrim, free and bold and light-hearted to contend against all the ills of the world?—FISKE *Through Nature to God,* pt. i, ch. 3, p. 11. (H. M. & Co., 1900.)

2584. PHILOSOPHY OF HABIT—Dr. Carpenter's phrase that our nervous system grows to the modes in which it has been exercised expresses the philosophy of habit in a nutshell.—JAMES *Psychology,* vol. i, ch. 4, p. 112. (H. H. & Co., 1899.)

2585. PHOSPHORESCENCE, BACTERIAL—*Cause of, Unknown.*—Several species of sea-water bacteria themselves possess powers of phosphorescence. Pflüger was the first to point out that it was such organisms which provided the phosphorescence upon decomposing wood or decaying fish. To what this light is due, whether capsule, or protoplasm, or chemical product, is not yet known. The only facts at present established are to the effect that certain kinds of media and pabulum favor or deter phosphorescence.—NEWMAN *Bacteria,* ch. 1, p. 26. (G. P. P., 1899.)

2586. PHOSPHORESCENCE OF DEEP SEA—*Animals Light Their Own Abode.*—Altho it is highly probable that not a glimmer of sunlight ever penetrates to the depths of the ocean, there is in some places, undoubtedly, a very considerable illumination due to the phosphorescence of the inhabitants of the deep waters. All the alcyonarians are, according to Moseley, brilliantly phosphorescent when brought to the surface. Many deep-sea fish possess phosphorescent organs, and it is quite possible that many of the deep-sea protozoa, tunicates, jellyfish, and crustacea are in their native haunts capable of giving out a very considerable amount of phosphorescent light.—HICKSON *Fauna of the Deep Sea,* ch. 2, p. 25. (A., 1894.)

2587. ——— ———*Light Not Universal—Caves of Darkness—Eyeless Organisms.*—The entire absence or rudimentary condition of the eyes of a very considerable

proportion of deep-sea animals seems to prove that the phosphorescent illumination is not universally distributed, and that there must be some regions in which the darkness is so absolute that it can only be compared with the darkness of the great caves.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 27. (A., 1894.)

2588. PHOSPHORESCENCE OF THE OCEAN — *Porpoises Swimming in Paths of Light.*—Standing at the bow and looking forwards, at a distance of forty or fifty yards from the ship, a number of luminous streamers were seen rushing towards us. On nearing the vessel they rapidly turned, like a comet round its perihelion, placed themselves side by side, and in parallel trails of light kept up with the ship. One of them placed itself right in front of the bow as a pioneer. These comets of the sea were joined at intervals by others. Sometimes as many as six at a time would rush at us, bend with extraordinary rapidity round a sharp curve, and afterwards keep us company. I leaned over the bow and scanned the streamers closely. The frontal portion of each of them revealed the outline of a porpoise. The rush of the creatures through the water had started the phosphorescence, every spark of which was converted by the motion of the retina into a line of light. Each porpoise was thus wrapped in a luminous sheath. The phosphorescence did not cease at the creature's tail, but was carried many porpoise-lengths behind it.—TYNDALL *Fragments of Science*, ch. 6, p. 149. (A., 1897.)

2589. ——— ——— *Radiance from Death.*—Sometimes one cannot, even with high magnifying powers, discover any animalcules in the luminous water; and yet, wherever a wave breaks in foam against a hard body, and, indeed, wherever water is violently agitated, flashes of light become visible. The cause of this phenomenon depends probably on the decomposing fibers of dead mollusca, which are diffused in the greatest abundance throughout the water. If this luminous water be filtered through finely woven cloths the fibers and membranes appear like separate luminous points. When we bathed at Cumana, in the Gulf of Cariaco, and walked naked on the solitary beach in the beautiful evening air, parts of our bodies remained luminous from the bright fibers and organic membranes which adhered to the skin, nor did they lose this light for some minutes. If we consider the enormous quantity of mollusca which animate all tropical seas, we can hardly wonder that sea-water should be luminous, even where no fibers can be visibly separated from it.—HUMBOLDT *Views of Nature*, p. 249. (Bell, 1896.)

2590. PHOSPHORUS, DELUSION OF —*Chemistry of Brain Action Little Known.* —Chemical action must of course accompany brain activity. But little definite is known of its exact nature. Cholesterin and creatin are both excrementitious products, and are both found in the brain. The subject belongs to chemistry rather than to psychology, and I only mention it here for the sake of saying a word about a wide-spread popular error about brain activity and phosphorus. "*Ohne Phosphor kein Gedanke* [no thought without phosphorus]" was a noted war-cry of the "materialists" during the excitement on that subject which filled Germany in the '60s. The brain, like every other organ of the body, contains phosphorus and a score of other chemicals besides. Why the phosphorus should be picked out as its essence, no one knows. It would be equally true to say "*Ohne Wasser kein Gedanke* [no thought without water]," or "*Ohne Kochsalz kein Gedanke* [no thought without salt]"; for thought would stop as quickly if the brain should dry up or lose its NaCl as if it lost its phosphorus. —JAMES *Psychology*, vol. i, ch. 3, p. 101. (H. H. & Co., 1899.)

2591. PHOTOGRAPHY AS AN AID TO ASTRONOMY—*A Photographic Survey of the Heavens.*—Perhaps the most marvelous of all achievements of photography is in the field of astronomy. Every increase in the size and power of the telescope has revealed to us ever more and more stars in every part of the heavens; but by the aid of photography stars are shown which no telescope that has been or that probably ever will be constructed, can render visible to the human eye. For by exposing the photographic plate in the focus of the object-glass for some hours almost infinitely faint stars impress their image, and the modern photographic star-maps show us a surface densely packed with white points that seem almost as countless as the sands of the seashore. . . . A photographic survey of the heavens is now in progress on one uniform system, which when completed will form a standard for future astronomers, and thus give to our successors some definite knowledge of the structure and perhaps of the extent of the stellar universe.—WALLACE *The Wonderful Century*, ch. 5, p. 32. (D. M. & Co., 1899.)

2592. PHOTOGRAPHY, CUMULATIVE EFFECT OF—*Extending Time of Exposure Compensates for Feebleness of Light—No Cumulative Power in the Eye—Vision the Recognition of a Series of Photographs.*—Seeing may be described, not wholly inaptly, as the recognition of a series of brief successive photographs taken by the optic lens on the retina; but the important difference between seeing and photographing, which we now ask attention to, is this: When the eye looks at a faint object, such as the spectrum of a star, or at the still fainter nebula, this, as we know, appears no brighter at the end of half an hour than at the end of the first half-second. In other words, after a brief fraction of a second, the visual effect does not sensibly accumulate. But in

the action of the photograph, on the contrary, the effect *does* accumulate, and in the case of a weak light accumulates indefinitely. It is owing to this precious property that, supposing (for illustration merely) the lightning flash to have occupied the one-thousandth part of a second in impressing itself on the plate, to get a nearly similar effect from a continuous light one thousand times weaker, we have only to expose the plate a thousand times as long—that is, for one second; while from a light a million times weaker we should get the same result by exposing it a million times as long—that is, for a thousand seconds.—LANGLEY *New Astronomy*, ch. 8, p. 244. (H. M. & Co., 1896.)

2593. PHOTOGRAPHY FINDS NO TRACE OF SUNLIGHT IN DEEP SEA—The more recent experiments that have been made tend to show that no sunlight whatever penetrates to a greater depth, to take an extreme limit, than 500 fathoms. Fol and Sarasin, experimenting with very sensitive bromo-gelatin plates, found that there was no reaction after ten minutes' exposure at a depth of 400 meters on a sunny day in March.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 25. (A., 1894.)

2594. PHOTOGRAPHY PICTURES THE INVISIBLE—*Finds Stars in the Blackness of Space.*—Mr. H. C. Russell, at Sydney, in 1890, successfully imitated Professor Barnard's example. His photographs of the southern Milky Way have many points of interest. They show the great rift, so black to the eye, as densely star-strewn to the perception of the chemical retina, while the "Coal-sack" appears absolutely dark only in its northern portion.—CLERKE *History of Astronomy*, pt. ii, ch. 12, p. 508. (Bl., 1893.)

2595. ——— ——— *The Photograph Secures What the Telescope Fails to Reveal—One Hour of Photographic Exposure Surpasses Years of an Astronomer's Labor.*—The writer remembers the interest with which he heard Dr. Draper, not long before his lamented death, speak of the almost incredible sensitiveness of these most recent photographic processes, and his belief that we were fast approaching the time when we should photograph what we could not even see. The time has now arrived. At Cambridge, in Massachusetts, and at the Paris Observatory, by taking advantage of the cumulative action we have referred to, and by long exposures, photographs have recently been taken showing stars absolutely invisible to the telescope, and enabling us to discover faint nebulæ whose previous existence had not been suspected; and when we consider that an hour's exposure of a plate now not only secures a fuller star-chart than years of an astronomer's labor, but a more exact one, that the art is every month advancing perceptibly over the last, and that it is already, as we may say, not only making pictures of what we see, but of what we cannot see even with the telescope, we have before us a prospect whose possibilities no further words are needed to suggest.—LANGLEY *New Astronomy*, ch. 8, p. 247. (H. M. & Co., 1896.)

2596. PHRENOLOGY, ABSOLUTE LIMIT OF—*Power of Brain Dependent on Convolutions.*—No account can be taken [by phrenology] of an increased number of convolutions. Supposing that the size of each faculty be due to the amount of gray matter in the convolution, then an additional convolution will greatly increase the amount of gray matter, but will not alter the shape of the skull situated above this portion of the brain. This is important, as, from observations which have been made, it is found that the brain is more convoluted in persons of superior intelligence.—ELDRIDGE-GREEN *Memory and Its Cultivation*, ch. 5, p. 38. (A., 1900.)

2597. PHRENOLOGY IGNORES ELEMENTS—*Answers Problem by Restatement.*—Phrenology hardly does more than restate the problem. To answer the question, "Why do I like children?" by saying, "Because you have a large organ of philoprogenitiveness," but renames the phenomenon to be explained. What is my philoprogenitiveness? Of what mental elements does it consist? And how can a part of the brain be its organ? A science of the mind must reduce such complex manifestations as "philoprogenitiveness" to their elements. A science of the brain must point out the functions of its elements. A science of the relations of mind and brain must show how the elementary ingredients of the former correspond to the elementary functions of the latter. But phrenology, except by occasional coincidence, takes no account of elements at all.—JAMES *Psychology*, vol. i, ch. 2, p. 28. (H. H. & Co., 1899.)

2598. PHYSICS, CELESTIAL—*The New Contrasted with the Old Astronomy—Study of the Nature, and Not Merely of the Position, of the Heavenly Bodies.*—The prime object of astronomy, until very lately, indeed, has still been to say where any heavenly body is, and not what it is. It is this precision of measurement, then, which has always—and justly—been a paramount object of this oldest of the sciences, not only as a good in itself, but as leading to great ends; and it is this which the poet of Urania has chosen rightly to note as its characteristic when he says:

> That little vernier, on whose slender lines
> The midnight taper trembles as it shines,
> Tells through the mist where dazzled Mercury burns,
> And marks the point where Uranus returns.

But within a comparatively few years a new branch of astronomy has arisen which studies sun, moon, and stars for what they are in themselves and in relation to ourselves. Its study of the sun, beginning with its external features (and full of novelty

and interest, even, as regards those), led to the further inquiry as to what it was made of, and then to finding the unexpected relations which it bore to the earth and our own daily lives on it, the conclusion being that, in a physical sense, it made us and re-creates us, as it were, daily, and that the knowledge of the intimate ties which unite man with it brings results of the most practical and important kind, which a generation ago were unguessed at.

This new branch of inquiry is sometimes called celestial physics, sometimes solar physics, and is sometimes more rarely referred to as the new astronomy.—LANGLEY *The New Astronomy*, ch. 1, p. 3. (H. M. & Co., 1896.)

2599. PHYSIOLOGY AGAINST THE MATERIALIST — *Thought Not in Brain—Molecular Movements Are but Concomitants of Mental Action.*—The only thing which cerebral physiology tells us, when studied with the aid of molecular physics, is against the materialist, so far as it goes. It tells us that during the present life, altho thought and feeling are always manifested in connection with a peculiar form of matter, yet by no possibility can thought and feeling be in any sense the products of matter. Nothing could be more grossly unscientific than the famous remark of Cabanis, that the brain secretes thought as the liver secretes bile. It is not even correct to say that thought goes on in the brain. What goes on in the brain is an amazingly complex series of molecular movements with which thought and feeling are in some unknown way correlated, not as effects or as causes, but as concomitants.—FISKE *Destiny of Man*, ch. 16, p. 109. (H. M. & Co., 1900.)

2600. PICTURE DRAWN BY LIGHTNING STROKE—*Form Photographed in Death.*—When a disruptive discharge takes place through the air between two conductors, in many cases a part of the matter of each conductor is transferred to the other. [Accounts have been] received . . . from different sources of a remarkable phenomenon connected with this action. In the case of a person killed many years ago by lightning, while standing near to the whitewashed wall of a room, the discharge took place between his body and the wall, and on the latter was depicted, in dark color, an image of his person. Other cases of the same kind had been observed.—HENRY *Scientific Writings*, vol. i, p. 293. (Sm. Inst., 1886.)

2601. PICTURE-WRITING—*Transition from Hieroglyph to Sound-sign—Phonograph Returns to the Actual Sound.*—In examining the methods of writing, we began with the rude hunter's pictures, passing on to the Egyptian's use of a picture to represent the sound of its name, then to the breaking down of the picture into a mere sound-sign, till in this last stage the connection between figure and sound becomes so apparently arbitrary that the child has to be taught, this sign stands for A, this for B. In curious contrast with this is the modern invention of the phonograph, where the actual sound spoken into the vibrating diaphragm marks indentations in the traveling strip of tinfoil, by which the diaphragm can be afterwards caused to repeat the vibrations and reutter the sound. When one listens to the tones coming forth from the strip of foil the South Sea Islander's fancy of the talking chip seems hardly unreasonable.—TYLOR *Anthropology*, ch. 7, p. 181. (A., 1899.)

2602. PIGMENTS DIFFER FROM RAYS—*No Natural Color Is Pure—Blue and Yellow Lights Do Not Make Green.*—You will find it stated in many books that blue and yellow lights mixed together produce green. But blue and yellow have been just proved to be complementary colors, producing white by their mixture. The mixture of blue and yellow pigments undoubtedly produces green, but the mixture of pigments is totally different from the mixture of lights. Helmholtz has revealed the cause of the green in the case of a mixture of blue and yellow pigments. No natural color is pure. A blue liquid or a blue powder permits not only the blue to pass through it, but a portion of the adjacent green. A yellow powder is transparent not only to the yellow light, but also in part to the adjacent green. Now, when blue and yellow are mixed together the blue cuts off the yellow, the orange, and the red; the yellow, on the other hand, cuts off the violet, the indigo, and the blue. Green is the only color to which both are transparent, and the consequence is that when white light falls upon a mixture of yellow and blue powders the green alone is sent back to the eye.—TYNDALL *Lectures on Light*, lect. 1, p. 37. (A., 1898.)

2603. PILOTS OF CIVILIZATION—*The Buffalo a Pioneer—Bison-tracks Show the Best Passes over Mountains.*—It is also a remarkable fact that the North-American bison, or buffalo, has exerted an influence on geographical discoveries in pathless mountain districts. These animals advance in herds of many thousands in search of a milder climate, during winter, in the countries south of the Arkansas River. Their size and cumbrous forms render it difficult for them to cross high mountains on these migratory courses, and a well-trodden buffalo-path is therefore followed wherever it is met with, as it invariably indicates the most convenient passage across the mountains. Thus buffalo-paths have indicated the best tracks for passing over the Cumberland Mountains in the southwestern parts of Virginia and Kentucky, and over the Rocky Mountains between the sources of the Yellowstone and Platte rivers, and between the southern branch of the Columbia and the Californian Rio Colorado.—HUMBOLDT *Views of Nature*, p. 42. (Bell, 1896.)

2604. PITCH LAKE OF TRINIDAD—*Dead Forests Decomposed by Volcanic Fires.*—Fluid bitumen is seen to ooze from the bottom of the sea on both sides of the island of Trinidad, and to rise up to the surface of the water. Near Cape La Braye there is a vortex which, in stormy weather, according to Captain Mallet, gushes out, raising the water five or six feet, and covers the surface for a considerable space with petroleum or tar; and the same author quotes Gumilla as stating, in his "Description of the Orinoco," that about seventy years ago a spot of land on the western coast of Trinidad, near half-way between the capital and an Indian village, sank suddenly and was immediately replaced by a small lake of pitch, to the great terror of the inhabitants.

It is probable that the great pitch lake of Trinidad owes its origin to a similar cause; and Dr. Nugent has justly remarked that in that district all the circumstances are now combined from which deposits of pitch may have originated. The Orinoco has for ages been rolling down great quantities of woody and vegetable bodies into the surrounding sea, where, by the influence of currents and eddies, they may be arrested and accumulated in particular places. The frequent occurrence of earthquakes and other indications of volcanic action in those parts lend countenance to the opinion that these vegetable substances may have undergone, by the agency of subterranean fire, those transformations and chemical changes which produce petroleum; and this may, by the same causes, be forced up to the surface, where, by exposure to the air, it becomes inspissated, and forms the different varieties of pure and earthy pitch, or asphaltum, so abundant in the islands.—LYELL *Principles of Geology*, bk. ii, ch. 16, p. 250. (A., 1854.)

2605. PITILESSNESS OF NATURAL FORCES—*Contrast with Human Power—The Sense of the Sublime.*—The air [on the Matterhorn] was preternaturally still; an occasional gust came eddying round the corner of the mountain, but all else seemed strangely rigid and motionless and out of keeping with the beating heart and moving limbs, the life and activity, of man. Those stones and ice have no mercy in them, no sympathy with human adventure; they submit passively to what man can do; but let him go a step too far, let heart or hand fail, mist gather or sun go down, and they will exact the penalty to the uttermost. The feeling of "the sublime" in such cases depends very much, I think, on a certain balance between the forces of Nature and man's ability to cope with them: if they are too weak, the scene fails to impress; if they are too strong for him, what was sublime becomes only terrible.—TYNDALL *Hours of Exercise in the Alps*, ch. 3, p. 44. (A., 1898.)

2606. PLACE OF BACTERIA IN NATURE—*First Deemed Animals—Now Ascertained To Be Plants—Animals Have No Monopoly of Motion.*—For a considerable period of time after their first detection these unicellular organisms [bacteria] were considered to be members of the animal kingdom. As late as 1838, when Ehrenberg and Dujardin drew up their classification, bacteria were placed among the infusorians. This was in part due to the powers of motion which these observers detected in bacteria. It is now, of course, recognized that animals have no monopoly of motion. But what, after all, are the differences between animals and vegetables so low down in the scale of life? Chiefly two: there is a difference in life history (in structure and development), and there is a difference in diet. . . . It is true, they [bacteria] possess motion, are free from chlorophyl, and even feed occasionally upon products of decomposition—three physiological characters which would ally them to the animal kingdom. Yet by their structure and capsule of cellulose and by their life history and mode of growth they unmistakably proclaim themselves to be of the vegetable kingdom. In 1853 Cohn arrived at a conclusion to this effect, and since that date they have become more and more limited in classification and restricted in definition.—NEWMAN *Bacteria*, ch. 1, p. 5. (G. P. P., 1899.)

2607. PLACE OF EXPERIMENTS IN SCIENCE—*The Investigator Addresses Inquiries to Nature—The Teacher Presents Her Answers to the Public.*—Experiments have two great uses—a use in discovery and verification, and a use in tuition. They were long ago defined as the investigator's language addressed to Nature, to which she sends intelligible replies. These replies, however, usually reach the questioner in whispers too feeble for the public ear. But after the discoverer comes the teacher, whose function it is so to exalt and modify the experiments of his predecessor as to render them fit for public presentation.—TYNDALL *Lectures on Light*, lect. 1, p. 3. (A., 1898.)

2608. PLACE OR PERSON JUMBLED IN MEMORY—*Accidental Association—Light on Some Questions of Veracity.*—Thus, for example, I may have lent a book to a friend last week. I really remember the act of lending it, but have forgotten the person. But I am not aware of this. The picture of memory has unknowingly to myself been filled up by this unconscious process of shifting and rearrangement, and the idea of another person has by some odd accident got substituted for that of the real borrower. If we could go deeply enough into the matter, we should, of course, be able to explain why this particular confusion arose. We might find, for example, that the two persons were associated in my mind by a link of resemblance, or that I had dealings with the other person about the same time.

Similarly, when we manage to join an event to a wrong place, we may find that it is because we heard of the occurrence when staying at the particular locality, or in some other way had the image of the place closely associated in our minds with the event. But often we are wholly unable to explain the displacement.—SULLY *Illusions*, ch. 10, p. 266. (A., 1897.)

2609. PLAN AND PURPOSE MARK HUMANITY—*Passion, Appetite, and Desire Subdued to One Supreme Volition.*—To plan, to purpose, . . . is to exercise all the faculties of developed manhood, under the control of will. Yet this, like all other complex manifestations of those faculties, is also matter of degrees. We should not, therefore, by any means confine our estimate of such products of will to those who can say with the Paracelsus of Browning:

> I have subdued my life to the one purpose
> Whereto I ordained it;

or, again:

> I have made my life consist of one idea,

however grand the idea and noble the sentiment belonging to the plan. The lower order of savages, and the average man of the civilized community, do indeed suffer themselves to be swayed by internal passions and external circumstances rather than "subdue" their lives to any "one purpose." And yet there is another side to all this. They, too, as sharers in the possibilities of human development, habitually take large sections, as it were, of their own lives into their own keeping; they "ordain" them to some one purpose (tho it may be no nobler purpose than to take vengeance on an enemy; to excel in trapping game, or in outdressing and outranking others, or in bulling or bearing the market): and they subdue ideas and feelings and minor volitions to this one purpose. They thus rise above the lower animals and show the leading characteristics of a distinctively human development.—LADD *Psychology*, ch. 26, p. 630. (S., 1899.)

2610. PLAN FOR SCIENTIFIC CONQUEST OF THE GLOBE—Humboldt gave the first impulse, at the Scientific Congress of Berlin in 1828, to a great international movement for attacking simultaneously, in various parts of the globe, the complex problem of terrestrial magnetism. Through the genius and energy of Gauss, Göttingen became its center. Thence new apparatus and a new system for its employment issued. . . . The letter addressed by Humboldt in April, 1836, to the Duke of Sussex as president of the Royal Society, enlisted the cooperation of England. A network of magnetic stations was spread all over the British dominions, from Canada to Van Diemen's Land; measures were concerted with foreign authorities, and an expedition was fitted out, under the able command of Captain (afterwards Sir James) Clark Ross, for the special purpose of bringing intelligence on the subject from the dismal neighborhood of the south pole. In 1841 the elaborate organization created by the disinterested efforts of scientific "agitators" was complete; Gauss's "magnetometers" were vibrating under the view of attentive observers in five continents, and simultaneous results began to be recorded. —CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 157. (Bl., 1893.)

2611. PLAN MANIFESTED BY BEES—*Scouts Select Home for New Colony.*—M. de Fravière had the opportunity of observing the manner in which such an examination [of a new hive, by bees] is carried on, and with what prudence and accuracy. He placed an empty beehive, made in a new style, in front of his house, so that he could exactly watch from his own window what went on inside and out without disturbance to himself or to the bees. A single bee came and examined the building, flying all round it and touching it. It then let itself down on the board, and walked carefully and thoroughly over the interior, touching it continually with its antennæ so as to subject it on all sides to a thorough investigation. The result of its examination must have been satisfactory, for after it had gone away it returned accompanied by a crowd of some fifty friends, which now together went through the same process as their guide. This new trial must also have had a good result, for soon a whole swarm came, evidently from a distant spot, and took possession. Still more remarkable is the behavior of the scouts when they take possession of a satisfactory hive or box for an imminent or approaching swarm. Altho it is not yet inhabited they regard it as their property, watch it and guard it against stranger bees or other assailants, and busy themselves earnestly in the most careful cleansing of it, so far as this cleansing is impossible to the setter up of the hive. Such a taking possession sometimes occurs eight days before the entrance of the swarm. —ROMANES *Animal Intelligence*, ch. 4, p. 168. (A., 1899.)

2612. PLAN REVEALED IN RUDIMENTARY ORGANS—*History or Prophecy.* —In this point of view rudimentary or aborted organs need no longer puzzle us, for in respect to purpose they may be read either in the light of history or in the light of prophecy. They may be regarded as indicating always either what had already been or what was yet to be. Why new creations should never have been made wholly new; why they should have been always molded on some preexisting forms; why one fundamental ground-plan should have been adhered to for all vertebrate animals—we cannot understand. But as a matter of fact, it is so.—ARGYLL *Reign of Law*, ch. 4, p. 122. (Burt.)

2613. PLANET COOLED BY CELESTIAL SPACES—*Crust Wrinkling into Mountains.*—Astronomy shows us our planet

thrown off from the central mass of which it once formed a part, to move henceforth in an independent orbit of its own. That orbit, it tells us, passed through celestial spaces cold enough to chill this heated globe, and of course to consolidate it externally. . . . The first effect of cooling the surface of our planet must have been to solidify it, and thus to form a film or crust over it. That crust would shrink as the cooling process went on; in consequence of the shrinking, wrinkles and folds would arise upon it; and here and there, where the tension was too great, cracks and fissures would be produced. In proportion as the surface cooled, the masses within would be affected by the change of temperature outside of them, and would consolidate internally also, the crust gradually thickening by this process.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 6. (H. M. & Co., 1896.)

2614. PLANETS REVOLVE ROUND OTHER SUNS—*Variation of Algol Due to Eclipse.*—The most celebrated variable star, Algol, or β Persei, examined many times at the epoch of its minimum brightness, has always shown the type of Vega . . . from which we may conclude that the variation of the star is not due to a chemical phenomenon, that the star does not change, and is doubtless eclipsed by a planet of its system which passes in front of it. This idea, previously suggested, of attributing the periodical diminution of the brightness of Algol to an eclipse produced by an opaque body revolving round the star, agrees, moreover, very well with the regularity of the phenomenon and with the short duration of the phase of light-diminution.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 612. (A.)

2615. PLANS, VAST AND IMPRESSIVE, OF PRIMITIVE MAN—*The Mound-builders' Creations.*—The enclosure known as "Clark's Work," in Ross County, Ohio, is one of the largest and most interesting. It consists of a parallelogram, two thousand eight hundred feet by eighteen hundred, and enclosing about one hundred and eleven acres. To the right of this, the principal work is a perfect square, containing an area of about sixteen acres. Each side is eight hundred and fifty feet in length, and in the middle of each is a gateway thirty feet wide, covered by a small mound. Within the area of the great work are several smaller mounds and enclosures, and it is estimated that not less than three millions of cubic feet of earth were used in this great undertaking. Yet from the peculiarly mottled character of the earth forming these mounds, it would appear to have been brought in bags or small parcels. It has also been observed that water is almost invariably found within or close to these enclosures.—AVEBURY *Prehistoric Times*, ch. 8, p. 245. (A 1900.)

2616. PLANT, INSECTIVOROUS, CLOSING ON ITS PREY—*Struggles of Victim Seal Its Doom.*—If a small organic or inorganic object be placed on the glands in the center of a leaf [of sundew], these transmit a motor impulse to the marginal tentacles. The nearer ones are first affected and slowly bend towards the center, and then those farther off, until at last all become closely inflected over the object. This takes place in from one hour to four or five or more hours. The difference in the time required depends on many circumstances; namely, on the size of the object and on its nature, that is, whether it contains soluble matter of the proper kind; on the vigor and age of the leaf; whether it has lately been in action; and, according to Nitschke, on the temperature of the day, as likewise seemed to me to be the case. A living insect is a more efficient object than a dead one, as in struggling it presses against the glands of many tentacles. An insect, such as a fly, with thin integuments, through which animal matter in solution can readily pass into the surrounding dense secretion, is more efficient in causing prolonged inflection than an insect with a thick coat, such as a beetle. The inflection of the tentacles takes place indifferently in the light and darkness; and the plant is not subject to any nocturnal movement of so-called sleep.—DARWIN *Insectivorous Plants*, ch. 1, p. 7. (A., 1900.)

2617. PLANT LIFTS MINERAL TO LIVING WORLD—*Divine Life Must Uplift from Natural to Spiritual World.*—There being no passage from one kingdom to another, whether from inorganic to organic, or from organic to spiritual, the intervention of life is a scientific necessity if a stone or a plant or an animal or a man is to pass from a lower to a higher sphere. The plant stretches down to the dead world beneath it, touches its minerals and gases with its mystery of life, and brings them up ennobled and transformed to the living sphere. The breath of God, blowing where it listeth, touches with its mystery of life the dead souls of men, bears them across the bridgeless gulf between the natural and the spiritual, between the spiritually inorganic and the spiritually organic, endows them with its own high qualities, and develops within them those new and secret faculties by which those who are born again are said to "see the kingdom of God."—DRUMMOND *Natural Law in the Spiritual World*, int., p. 64. (H. Al.)

2618. PLANTS EXTENDED BY RUNNERS—*Numerous Progeny of a Single Plant.*—The spreading of strawberries by runners must be familiar to every observer. In 1894 a student reported that a wild strawberry plant in the botanic garden had produced in that year 1,230 plants. Weeds were all kept away, the season was favorable, the soil sandy; but on one side, within a foot

and a half, progress was checked by the presence of a large plant of another kind.—BEAL *Seed Dispersal*, ch. 3, p. 13. (G. & Co., 1898.)

2619. PLANTS IN SUBTERRANEAN CAVITIES—*Ejected in Volcanic Eruption.*—In what manner did the solid coverings of these most minute plants and animalcules, which can only originate and increase at the surface of the earth, sink down and penetrate into subterranean cavities, so as to be ejected from the volcanic orifices? We have of late years become familiar with the fact, in the process of boring Artesian wells, that the seeds of plants, the remains of insects, and even small fish, with other organic bodies, are carried in an uninjured state by the underground circulation of waters, to the depth of many hundred feet. With still greater facility in a volcanic region we may conjecture that water and mud full of invisible infusoria may be sucked down, from time to time, into subterranean rents and hollows in cavernous lava which has been permeated by gases, or in rocks dislocated by earthquakes. It often happens that a lake which has endured for centuries in a volcanic crater disappears suddenly on the approach of a new eruption. Violent shocks agitate the surrounding region, and ponds, rivers, and wells are dried up. Large cavities far below may thus become filled with fen mud chiefly composed of the more indestructible and silicious portions of infusoria, destined, perhaps, to be one day ejected in a fragmentary or half-fused state, yet without the obliteration of all traces of organic structure.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 389. (A., 1854.)

2620. PLANTS OF NORTH AMERICA FOUND IN JAPAN—*Poison-ivy and Poison-oak—Correspondence of Far-off Lands.*—Our *Rhus Toxicodendron*, or poison-ivy, is very exactly repeated in Japan, but is found in no other part of the world, altho a species much like it abounds in California. Our other poisonous *rhus (R. venenata)*, commonly called poison-dogwood, is in no way represented in Western America, but has so close an analog in Japan that the two were taken for the same by Thunberg and Linnæus, who called them both *R. vernix*.—ASA GRAY *Darwiniana*, art. 5, p. 221. (A., 1889.)

2621. PLANTS PROTECTED AGAINST USELESS INSECTS—*Slippery Surfaces an Impassable Barrier.*—Protection [of many flowers against ants is secured] by means of slippery surfaces. In this case, also, the leaves often form a collar round the stem, with curvèd surfaces over which ants cannot climb. "I have assured myself," says Kerner, "not only by observation, but by experiment, that wingless insects, and notably ants, find it impossible to mount upwards over such leaves as these. The little creatures run up the stem, and may even not unfrequently traverse the undersurface of the leaves, if not too smooth; but the reflexed and slippery margin is more than the best climbers among them can get over, and if they attempt it they invariably fall to the ground. There is no necessity for the lamina of the leaf to be very broad; even narrow leaves, as, for instance, those of *Gentiana firma*, are enough for the purpose, supposing, of course, that the margin is bent backwards in the way described." Of this mode of protection the cyclamen and snowdrop offer familiar examples. In vain do ants attempt to obtain access to such flowers: the curved surfaces baffle them; when they come to the edge they inevitably drop off to the ground again. In fact, these pendulous flowers protect the honey as effectually from the access of ants as the hanging nests of the weaver and other birds protect their eggs and young from the attacks of reptiles.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 52. (A., 1900.)

2622. PLANTS SUPPLIED WITH NITROGEN BY MICRO-ORGANISMS—*Bacteria of Nitrification.*—Nitrification occurs in two stages, each stage performed by a distinct organism. By one *(nitrosomonas)*, ammonia is converted into nitrite; by the other *(nitrobacter)*, the nitrite is converted into nitrate [in which latter form alone the plant can use it]. Both organisms are widely and abundantly distributed in the superficial soils. They act together and in conjunction and for one common purpose. They are separable by employing favorable media. . . . They belong to the soil, river-water, and sewage. They are also said to be frequently present in well-water. From some experiments at Rothamsted it appears that the organisms occur mostly in the first twelve inches, and in subsoils of clay down to three or four feet. In sandy soils nitrification may probably occur at a greater depth.—NEWMAN *Bacteria*, ch. 5, p. 158. (G. P. P., 1899.)

2623. PLANTS WITH GOOD INTENTIONS—*A Relapse into Parasitism—The Dodder.*—There are certain plants—the dodder, for instance—which begin life with the best intentions, strike true roots into the soil, and really appear as if they meant to be independent for life. But after supporting themselves for a brief period they fix curious sucking disks into the stem and branches of adjacent plants. And after a little experimenting, the epiphyte finally ceases to do anything for its own support, thenceforth drawing all its supplies ready-made from the sap of its host. In this parasitic state it has no need for organs of nutrition of its own, and Nature therefore takes them away. Henceforth, to the botanist, the adult dodder presents the degraded spectacle of a plant without a root, without a twig, without a leaf, and having a stem so useless as to be inadequate to bear its own weight.—DRUMMOND *Natural Law in the Spiritual World*, essay 9, p. 285. (H. Al.)

2624. PLASTICITY CHARACTERIZES LIFE—*The Crystal Changeless—The Plant Immobile—The Animal Free—The Soul More Mobile Still.*—Now plasticity is not only a marked characteristic of all forms of life, but in a special sense of the highest forms. It increases steadily as we rise in the scale. The inorganic world, to begin with, is rigid. A crystal of silica dissolved and redissolved a thousand times will never assume any other form than the hexagonal. The plant next, tho plastic in its elements, is comparatively insusceptible of change. The very fixity of its sphere, the imprisonment for life in a single spot of earth, is the symbol of a certain degradation. The animal in all its parts is mobile, sensitive, free; the highest animal, man, is the most mobile, the most at leisure from routine, the most impressionable, the most open for change. And when we reach the mind and soul this mobility is found in its most developed form. Whether we regard its susceptibility to impressions, its lightning-like response even to influences the most impalpable and subtle, its power of instantaneous adjustment, or whether we regard the delicacy and variety of its moods or its vast powers of growth, we are forced to recognize in this the most perfect capacity for change. This marvelous plasticity of mind contains at once the possibility and prophecy of its transformation.—DRUMMOND *Natural Law in the Spiritual World,* essay 8, p. 269. (H. Al.)

2625. PLATES, THIN, COLORS OF—*Illustrated by Colored Films on Molten Lead.*—"We took a quantity of clean lead and melted it with a strong fire, and then immediately pouring it out into a clean vessel of convenient shape and matter (we used one of iron, that the great and sudden heat might not injure it), and then carefully and nimbly taking off the scum that floated on the top we perceived, as we expected, the smooth and glossy surface of the melted matter to be adorned with a very glorious color, which being as transitory as delightful did almost immediately give place to another vivid color, and that was as quickly succeeded by a third, and this, as it were, chased away by a fourth; and so these wonderfully vivid colors successively appeared and vanished till the metal, ceasing to be hot enough to hold any longer this pleasing spectacle, the colors that chanced to adorn the surface when the lead thus began to cool remained upon it, but were so superficial that how little soever we scraped off the surface of the lead we did, in such places, scrape off all the color." [See FILMS; COLORS; LIGHT, DOUBLE REFLECTION OF.]—BOYLE *Experimental History of Colors,* quoted by TYNDALL in *Lectures on Light,* lect. 2, p. 68. (A., 1898.)

2626. PLAY AN INDICATION OF INTELLIGENCE—Over against the countless varieties of the play of children, reflecting all conceivable relations of life, stands the single form of mock fighting among the animals. (Trained animals do not, of course, concern us; their performances are not real play.) Dogs, cats, and monkeys, even when they are playing with their young, show their affection by pretending to fight with them. And tho it is true that play is an indication of high mental development, and brings the animal nearer to ourselves than any other activity, it is rather the fact that it plays than the nature of the play itself which is the important point. . . . Animal play never shows any inventiveness, any regular and orderly working out of some general idea.—WUNDT *Psychology,* lect. 24, p. 358. (Son. & Co., 1896.)

2627. PLAY AS AN ART OF PLEASURE—*Sports of Children Imitative.*—Play is one of the arts of pleasure. It is doing for the sake of doing, not for what is done. One class of games is spontaneous everywhere, the sports in which children imitate the life they will afterwards have to act in earnest. Eskimo children play at building snow-huts, and their mothers provide them with a tiny oil-lamp with a bit of wick to set burning inside. Among the savages whose custom it is to carry off their wives by force from neighboring tribes, the children play at the game of wife-catching, just as, with us, children play at weddings with a clergyman and bridesmaids. All through civilization toy weapons and implements furnish children at once play and education; the North-American warrior made his boy a little bow and arrow as soon as he could draw it, and the young South Sea Islander learned by throwing a reed at a rolling ring how in after-life to hurl his spear. It is curious to see that when growing civilization has cast aside the practical use of some ancient contrivance it may still survive as a toy, as where Swiss children to this day play at making fire by the Old-World plan of drilling one piece of wood into another; and in our country lanes the children play with bows and arrows and slings, the serious weapons of their forefathers.—TYLOR *Anthropology,* ch. 12, p. 305. (A., 1899.)

2628. PLAY OF YOUNG ANIMALS AND OF CHILDREN—The play of man and the animals differs in the same way as their "intelligence." We regard certain actions of the higher animals as playful when they take the form of imitations of purposive voluntary actions. We know that they are imitations because the end pursued is only a fictitious end—the real end being excitation of joyous emotions similar to those which follow as secondary effects from genuine purposive action. That means, you see, that the play of animals is, for all practical purposes, identical with play among mankind. Our own play, at least in its simpler forms—*e. g.*, in the play of children—is merely an imitation of the actions of every-day life

stripped of its original purpose, and resulting in pleasurable emotion.—WUNDT *Psychology*, lect. 24, p. 357. (Son. & Co., 1896.)

2629. PLAYHOUSES OF THE BOWER-BIRD—*Love of the Beautiful—Esthetic Sense in Animals—Stealing of Bright and Attractive Objects.*—Some animals exhibit emotions of the beautiful. The following is Mr. Gould's description, *in extenso*, of the habits of the bower-bird of New South Wales: The extraordinary bower-like structure, alluded to in my remarks on the genus, first came under my notice in the Sydney Museum, to which an example had been presented by Charles Cox, Esq. . . . On visiting the cedar bushes of the Liverpool Range, I discovered several of these bowers or playing-houses on the ground, under the shelter of the branches of the overhanging trees, in the most retired part of the forest; they differed considerably in size, some being a third larger than others. The base consists of an extensive and rather convex platform of sticks firmly interwoven, on the center of which the bower itself is built. This, like the platform on which it is placed, and with which it is interwoven, is formed of sticks and twigs, but of a more slender and flexible description, the tips of the twigs being so arranged as to curve inwards and nearly meet at the top; in the interior the materials are so placed that the forks of the twigs are always presented outwards, by which arrangement not the slightest obstruction is offered to the passage of the birds. The interest of this curious bower is much enhanced by the manner in which it is decorated with the most gaily colored articles that can be collected, such as the blue tail-feathers of the Rose-hill and Pennantian parrakeets, bleached bones, and shells of snails, etc.; some of the feathers are inserted among the twigs, while others, with the bones and shells, are strewed near the entrances. The propensity of these birds to fly off with any attractive object is so well known to the natives that they always search the runs for any small missing article that may have been accidentally dropped in the bush. I myself found at the entrance of one of them a small, neatly worked stone tomahawk of an inch and a half in length, together with some slips of blue cotton rag, which the birds had doubtless picked up at a deserted encampment of the natives.—ROMANES *Animal Intelligence*, ch. 10, p. 279. (A., 1899.)

2630. PLEASURE AND PAIN, EXPRESSION OF—*Tension or Relaxation of Muscles.*—In this law of pleasure and pain we have the key to the leading varieties of expression of the feelings. The organs of expression by movement are primarily the features, next the voice, lastly the movements and gestures of the body at large—head, trunk, and extremities. In pleasurable emotions these are unquestionably rendered active; the grimaces, gestures, and attitudes show an accession of active power. The notable circumstances in this display are the general erection of the body, the opening up of the features, the powerful exercise of the voice; all showing that the extensor muscles, which are by far the largest, are strongly stimulated. When we have surplus energy to expend we stretch and extend the body in preference to bending and relaxing it; the weight of the body itself is borne in the one case and not in the other. Any additional strain, as in walking, lifting weights, rowing a boat, is borne by the extensor muscles. It is the size of these that makes the muscular figure, the fulness of the calves, the thighs, and the hips. On the other hand, pain (not violently acute), dejection, depression, leads to the relaxation of all these powerful muscles; hence a general stooping and collapse of the figure, showing that the springs of muscular force have dried up. The difference of the two situations, as regards the carriage of the whole body, is most marked. Compare the victor in a triumph with one of his captives—the attitude of the beater with the beaten. And as regards the face, how much is suggested by the one descriptive trait, "His countenance fell"!—BAIN *Mind and Body*, ch. 4, p. 17. (Hum., 1880.)

2631. PLEASURE, STRANGE, IN DESOLATION—*The Question of the Wilderness.*—The plain as usual consisted of gravel, mingled with soil resembling chalk in appearance, but very different from it in nature. From the softness of these materials it was worn into many gulleys. There was not a tree, and, excepting the guanaco, which stood on the hilltop, a watchful sentinel over its herd, scarcely an animal or a bird. All was stillness and desolation. Yet in passing over these scenes, without one bright object near, an ill-defined but strong sense of pleasure is vividly excited. One asked how many ages the plain had thus lasted, and how many more it was doomed thus to continue.

> None can reply—all seems eternal now.
> The wilderness has a mysterious tongue,
> Which teaches awful doubt.
> —SHELLEY, *Lines on Mont Blanc.*

—DARWIN *Naturalist's Voyage around the World*, ch. 8, p. 168. (A., 1898.)

2632. PLEDGE, UTILITY OF—*A Strong Initiative.*—In the acquisition of a new habit or the leaving off of an old one, we must take care to launch ourselves with as strong and decided an initiative as possible. Accumulate all the possible circumstances which shall reenforce the right motives; put yourself assiduously in conditions that encourage the new way; make engagements incompatible with the old; take a public pledge, if the case allows; in short, envelop your resolution with every aid you know. This will give your new beginning such a momentum that the temptation to break down will not occur as soon as it otherwise

might; and every day during which a break-down is postponed adds to the chances of its not occurring at all.—JAMES *Talks to Teachers*, ch. 8, p. 67. (H. H. & Co., 1900.)

2633. PLEIADES, ORIGIN OF THE NAME—*The Mariner's Guide in Heaven.*—The Pleiades [were] doubtless known to the rudest nations from the earliest times; the mariner's stars—Pleias, ἀπὸ τοῦ πλεῖν (from πλεῖν, to sail), according to the etymology of the old scholiast of Aratus, who is probably more correct than those modern writers who would derive the name from πλεός plenty. The navigation of the Mediterranean lasted from May to the beginning of November, from the early rising to the early setting of the Pleiades.—HUMBOLDT *Cosmos*, vol. iii, p. 141. (H., 1897.)

2634. POET SHOWS TRUE SCIENTIFIC INSIGHT—The description given by Strabo and Pausanias of this elevation [the Hill of Methone, now Methana, in the peninsula of Trœzene] led one of the Roman poets, most celebrated for his richness of fancy, to develop views which agree in a remarkable manner with the theory of modern geognosy. "Near Trœzene is a tumulus, steep and devoid of trees, once a plain, now a mountain. The vapors enclosed in dark caverns in vain seek a passage by which they may escape. The heaving earth, inflated by the force of the compressed vapors, expands like a bladder filled with air, or like a goatskin. The ground has remained thus inflated, and the high projecting eminence has been solidified by time into a naked rock." Thus picturesquely and, as analogous phenomena justify us in believing, thus truly has Ovid described that great natural phenomenon which occurred 282 years before our era.—HUMBOLDT *Cosmos*, vol. i, p. 240. (H., 1897.)

2635. POETRY HAS EXISTED WITHOUT SCIENCE—*Knowledge Increases Appreciation of the Order, Rhythm, and Beauty of Nature.*—I do not thus think well, or indeed anything, of the doctrine that a poetry nursed in utter ignorance of the scientific aspects of Nature presents us with an essentially typical development of the poetic faculty. No one can deny that in the absence of all scientific knowledge, that faculty may be developed to sing in loftiest strains and fullest measure. But I enter a strong protest against the misrepresentation that the scientific faculty destroys the poetic, or that, of necessity, an exact method of looking at things should utterly annul the sense wherewith we discover their external beauty or the wondrous and subtle rhythm and measure that pervade the universe at large.—ANDREW WILSON *Science and Poetry*, p. 10. (Hum., 1888.)

2636. POETRY, INDESTRUCTIBLE POWER OF—*Science Not to Supersede—The Poetry of Science.*—That poetry must ever assert a powerful influence on man's estate, no reasonable being may doubt. It is too closely bound up with the personal history of man in all stages of civilization, too nearly related to his inmost mind, as the expression of his deepest emotions, to fall into decay even when it lights upon a grossly utilitarian time. The song of victory, the pæan of joy, the "*Io triumphe*" of the conqueror, or the coronach and lament for the dead, are expressions wherein the true poetry of our nature bursts forth in spite of ourselves; whilst developing from these more rugged and primitive sources, as a softened stream passes sidewards from a mountain torrent, we find the cultured soul of the poet communing with Nature, and teaching us new and better feelings, and the glory of a higher life. It is not saying too much, then, to predict that the true mission of poetry is that of leading us to see fairer aspects of things, to cultivate the beauty-sense, and to lead us to see Nature in her thousand moods, even if the thoughts it evokes are ofttimes "too deep for tears." Poetry thus becomes the handmaid of culture, and still more of religion. Science it may never attempt to supersede, altho there is and must be a poetry of knowledge. . . . But poetry, as the expression of the deepest emotions of the human soul, can never fade. In her records lie embalmed, as in a treasure-house, the thoughts of the far-back past, and the noblest sentiments which humanity may express. Such are the functions of true poesy, and such the mission of those

Who on earth have made us heirs
Of truth and pure delight by heavenly lays!

—ANDREW WILSON *Science and Poetry*, p. 11. (Hum., 1888.)

2637. POINTS, DEBATABLE, SETTLED—*Many Nebulæ Are Star-clusters—Some Are Certainly Gas-clouds.*—I have spoken hitherto of nebulæ as star-cloudlets, and unquestionably large numbers of these objects are really composed of stars, and give forth the same sort of light (in general respects) as our sun and other single stars. But others have been shown by the researches of our great physicist, Dr. Huggins, to be composed of luminous gas or vapor. The famous nebula in Orion is among the number thus constituted; so are the dumb-bell nebula in Vulpecula, the ring nebula in Lyra, and other well-known objects. In the southern hemisphere the great nebula in Argo has been shown to be gaseous (by Captain Herschel), and the fine, irregular nebula in the greater Magellanic Cloud is another of these gaseous masses. The strange objects called the planetary nebulæ are also all gaseous, so far as these researches have yet extended.—PROCTOR *Our Place among Infinities*, p. 227. (L. G. & Co., 1897.)

2638. POISON, ALCOHOL A—*Is It also a Food?*—The reader of this paper may criticize the wording of the question contained

in the title, for no one can dispute that alcohol is a poison, that it can destroy animal or vegetable protoplasm, that if taken in large doses it produces disease and has a paralyzing action, and, like all other poisons, if taken in small doses it has a stimulating effect. The question, therefore, ought to read: Can alcohol, despite its unquestionable toxic properties, also act as a food?—KASSOWITZ *Is Alcohol a Food or a Poison? (a Lecture)*, p. 1. (Translation by Mrs. J. H. W. STUCKENBERG.)

2639. ——— ——— *Phosphorus Has Closely Similar Effects—Neither To Be Classed as a Food.*—Since alcohol has a destructive action upon protoplasm, and since the process of oxidation of protoplasm is intimately connected with its activity, it is self-evident that a diminution in the amount of protoplasm must entail a diminished decomposition of protoplasm due to this activity, and hence, also, a diminished oxidation of its decomposition products.

That the action of a poison actually can lead to such results is plainly evident in the consequences of phosphoric poisoning, which, precisely like alcoholic poisoning, leads, on the one hand, to an increased excretion of nitrogen, an expression of toxic destruction of protoplasm, and, on the other, to a very considerable decrease in the taking in of oxygen and the giving out of carbon dioxid. Of course, it is not to be thought of that the oxidation of the small quantity of phosphorus ample to produce that effect could save fat by withdrawing the oxygen at its disposal; rather, it is perfectly clear that the protoplasm destroyed by the poisonous action of phosphorus (while fat is split off and nitrogen excreted) can no longer take part in the vital processes of oxidation. Hence, if we chose to call the toxic alcohol a food on the ground that it limits physiological processes of oxidation by means of destroying protoplasm, we should be obliged to declare phosphorus a much more valuable food, because much smaller doses diminish the normal processes of oxidation by destroying protoplasm. But even the most rigid doctrinaire could scarcely be made to agree with this view.—KASSOWITZ *Is Alcohol a Food or a Poison? (a Paper)*, p. 13. (Translation by Mrs. J. H. W. STUCKENBERG.)

2640. POISON OF CAYENNE—*Aids to Digestion—Dinner Pills—Attempt to Evade Penalty of Overindulgence—Illness in India.*—The mere condiment is a stimulating drug that does its work directly upon the inner lining of the stomach by exciting it to increased and abnormal activity. A dyspeptic may obtain immediate relief by using Cayenne pepper. Among the advertised patent medicines is a pill bearing the very ominous name of its compounder, the active constituent of which is Cayenne. Great relief and temporary comfort are commonly obtained by using it as a "dinner pill." If thus used only as a temporary remedy for an acute or temporary or exceptional attack of indigestion, all is well, but the Cayenne, whether taken in pills or dusted over the food or stewed with it in curries or any other wise, is one of the most cruel of slow poisons when taken habitually. Thousands of poor wretches are crawling miserably towards their graves, the victims of the multitude of maladies of both mind and body that are connected with chronic, incurable dyspepsia, all brought about by the habitual use of Cayenne and its condimental cousins.

The usual history of these victims is that they began by overfeeding, took the condiment to force the stomach to do more than its healthful amount of work, using but a little at first. Then the stomach became tolerant of this little, and demanded more; then more, and more, and more, until at last inflammation, ulceration, torpidity, and finally the death of the digestive powers, accompanied with all that long train of miseries to which I have referred. India is their special fatherland.—WILLIAMS *Chemistry of Cookery*, ch. 15, p. 260. (A., 1900.)

2641. POISONING, CUMULATIVE, FROM SUPPOSEDLY INNOCENT SUBSTANCE—*Boracic Acid as a Preservative of Milk.*—Boracic acid is one of the most useful antiseptics with which to wash sore eyes or preserve tinned foods or milk. It is not a strong germicide, but an unirritating and effective wash. Many cases of its addition to milk have found their way into the law courts, owing to cumulative poisoning, and it should only be used with the very greatest care as a food preservative.—NEWMAN *Bacteria*, ch. 9, p. 322. (G. P. P., 1899.)

2642. POISONS OF MICROBES MUTUALLY DESTRUCTIVE—*Antagonisms of Bacteria.*—Whatever [direct] opposition one species affords to another it is able to exercise by means of its poisonous properties. These are of two kinds. There is, as is now widely known, the poisonous product named the *toxin*. . . . There is also in many species, as Dr. Klein has pointed out, a poisonous constituent or constituents included in the body protoplasm of the bacillus, and which he therefore terms the *intracellular poison*. Now, whilst the former is different in every species, the latter may be a property common to several species. Hence those having a similar intracellular poison are antagonistic to each other, each member of such a group being unable to live in an environment of its own intracellular poison. Further, it has been suggested that there are organisms possessing only one poisonous property, namely, their toxin—for example, the bacilli of tetanus and diphtheria—whilst there are other species, as above, possessing a double poisonous property, an intracellular poison and a toxin. In this latter class would be included the bacilli of anthrax and tubercle.—NEWMAN *Bacteria*, ch. 1, p. 34. (G. P. P., 1899.)

2643. POLARIZATION OF LIGHT—*Tourmalin Quenches All but One Set of Vibrations—Two Crossed Plates Produce Darkness.*—We may begin the study of the polarization of light, with ease and profit, by means of a crystal of tourmalin. But we must start with a clear conception of an ordinary beam of light. It has been already explained that the vibrations of the individual ether-particles are executed across the line of propagation. In the case of ordinary light we are to figure the ether-particles as vibrating in all directions, or azimuths, as it is sometimes expressed, across this line. Now, in the case of a plate of tourmalin cut parallel to the axis of the crystal, a beam of light incident upon the plate is divided into two, the one vibrating parallel to the axis of the crystal, the other at right angles to the axis. The grouping of the molecules and of the ether associated with the molecules reduces all the vibrations incident upon the crystal to these two directions. One of these beams, namely, that whose vibrations are perpendicular to the axis, is quenched with exceeding rapidity by the tourmalin. To such vibrations many specimens of the crystal are highly opaque, so that, after having passed through a very small thickness of the tourmalin, the light emerges with all its vibrations reduced to a single plane. In this condition it is what we call *plane polarized light.*

A moment's reflection will show that, if what is here stated be correct, on placing a second plate of tourmalin with its axis parallel to the first, the light will pass through both; but that, if the axes be crossed, the light that passes through the one plate will be quenched by the other, a total interception of the light being the consequence.—TYNDALL *Lectures on Light,* lect. 3, p. 115. (A., 1898.)

2644. POLITICS AN EDUCATION—*Increasing Knowledge of Social Laws—Provision against Pauperism.*—The very attempt of the working classes to govern through combination their own affairs, and to determine their own condition, is an education in itself. On the extended scale on which that attempt is being made it must accustom them to consider great general causes, and to estimate the manner and the degree in which these can be effected by the methods of adjustment. Last, not least, it must lead them to study and to recognize the moral duties which are indeed the most fundamental of all natural laws. For it ought to be remembered that the first and most important object of combinations is one against which there can be no opposition founded on the doctrines of economic science. That object is to secure for the working classes those provisions against misfortune, sickness, accident, and age which are amongst the first duties of all organized societies of men. How far through such agency the causes of pauperism may be successfully attacked is a question on which we are only entering. In like manner, the conditions and limitations under which combination may succeed in blending the functions and in uniting the profits of capital and of labor—this also is a question to be determined by natural laws, not yet fully explored or understood.—ARGYLL *Reign of Law,* ch. 7, p. 226. (Burt.)

2645. POLLUTION AT THE SOURCE—*Foul Springs and Wells Spread Disease.*—Gathering-grounds are frequently the locality of the pollution. The recent Maidstone epidemic is an example. Here some of the springs supplying the town with water were contaminated by several typhoid patients. Frequently on the gathering-ground one may find a number of houses the waste and refuse of which will furnish ample surface pollution, which in its turn may readily pass into a collecting reservoir or a well. Only recently the writer investigated the cause of typhoid in a large country house, and traced it to pollution of the private well by surface washings from the stable quarters. Leakage of house-drains into wells is not an infrequent source of contamination.—NEWMAN *Bacteria,* ch. 2, p. 82. (G. P. P., 1899.)

2646. POLYGAMY NOT PRIMEVAL—*General Equality of the Sexes.*—We have seen that the cruel treatment of the female sex is almost universal among savages, and that it is entirely unknown among the lower animals. It is in the highest degree improbable and unnatural to suppose that this habit can have been primeval. But the same considerations carry us a great deal farther. They raise a presumption in favor of the later origin of other habits and customs which are not confined to the savage state, but have prevailed and do now prevail among nations comparatively civilized [such as polygamy and marriage by capture.] There can have been no polygamy when as yet there was only a single pair, or when there were several single pairs widely separated from each other. The presumption, if not the certainty, therefore, is that primeval man must have been monogamous. It is a presumption supported by the general equality of the sexes in respect to the numbers born, with only just such an excess of the male sex as tends to maintain that equality against the greater risks to life arising out of manly pursuits and duties. Thus the facts of Nature point to polygamy as in all probability a departure from the habits of primeval times.—ARGYLL *Unity of Nature,* ch. 10, p. 229. (Burt.)

2647. POTTER'S WHEEL KNOWN FROM EARLY ANTIQUITY—All power at first was hand power; the machinery of the world was moved only by human muscles. . . . Winds and water currents gradually have been domesticated for human uses in savagery. The study of these is

essential to a knowledge of industrial progress. The Zuñi woman's extremely simple potter's wheel, which is nothing more than the turning of her vessel about in a box of dry sand as the work goes on, is only a little more rude than the fashion in the interior of China of putting a lump of clay on the top of a revolving shaft which they turn with one hand while the pot is formed with the other. The potter's wheel was known in the world from high antiquity. The Africans push a mass of clay around with one hand and form it with the other. —MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology,* p. 80). (Sch. R. C.)

2648. POTTERY, ANCIENT, MODELED ON BASKETWORK — Prompted, it may be, by the very act of making a coiled basket, the ancient potter rolled out a fillet or slender cylinder of prepared paste about the thickness, say, of a chalk crayon. Every one who reads these lines has more than once seen children playing with putty, rolling it out into fillets and then coiling it. The cook also makes little cakes after the same process, and the tidy housewife supplies herself thus with mats for her tables.

The ancient potter also coiled her fillet of soft clay around and around in an orderly manner, pinching as she went. . . . This work was done occasionally on the outside of a basket, bowl, or another vase. But the work was more frequently built up by the hands, guided chiefly by the eye, until the vessel was finished. Luckily for the student, many vessels are left in the corrugated condition produced by the pinching and coiling. These examples not only show the process here referred to, but they evidence a marvelous variety of finger-nail and finger-tip work.—MASON *Woman's Share in Primitive Culture,* ch. 5, p. 98. (A., 1894.)

2649. POTTERY, IMPORTANCE OF, TO PRIMITIVE MAN — Before the introduction of metallic vessels the art of the potter was more important even than it is at present. Accordingly, the sites of all ancient habitations are generally marked by numerous fragments of pottery; this is as true of the ancient Indian settlements as of the Celtic towns of England or the lake villages of Switzerland.—AVEBURY *Prehistoric Times,* ch. 8, p. 242. (A., 1900.)

2650. POTTERY, ORIGIN OF, LOST IN PREHISTORIC TIMES—*The Potter's Wheel in Egypt—A Type of Creation—Hand-made Pottery in Hebrides.*—In Europe, as any museum of antiquities shows, the funeral urns and other earthen vessels of the Stone and Bronze ages were hand-made; and even now tourists who visit the Hebrides buy earthen cups and bowls of an old woman who makes them in ancestral fashion without a potter's wheel, and ornaments them with lines drawn with a pointed stick. Yet the potter's wheel was known in the world from high antiquity . . . , as shown in the wall-paintings of the Tombs of the Kings. It is seen that they turned the wheel by hand. So the Hindu potter is described as now going down to the riverside when a flood has brought him a deposit of fine clay, when all he has to do is to knead a batch of it, stick up his pivot in the ground, balance the heavy wooden table on the top, give it a spin round, and set to work. It was an improvement on this simplest wheel to work it from below by the foot, and in our potteries a laborer drives it with a wheel and band, but the principle remains unchanged. As we watch with untiring pleasure the potter with this simple machine so easily bringing shape out of shapelessness, we can well understand how in the ancient world it seemed the very type of creation, so that the Egyptians pictured one of their deities as a potter molding man on the wheel.—TYLOR *Anthropology,* ch. 11, p. 274. (A., 1899.)

2651. POTTERY, PRIMITIVE — *The Work of Woman—Made To Meet the Demand for Cooking.*—Women were the first ceramic artisans and developed all the technic, the forms, and the uses of pottery. The inventions concerned in this industrial progress are far-reaching in their own extent, in the influence which they have had in the refinement and development of women, and in the rewards of happiness which they brought to the races and tribes favored by their presence. . . . Pottery or earlier substitutes therefor had no place in the kitchen until the mush-making or meat-seething stage of cookery had arrived.—MASON *Woman's Share in Primitive Culture,* ch. 5, p. 91. (A., 1894.)

2652. ——— ——— *Once Made by Women, Still Made for Women.*—Long ago women made pottery for themselves to wear out and only a little for the convenience or delight of men. The very first woman that made pottery, perhaps, set the vessel on her head and went to the spring for water. A procession of women have been walking about over the earth ever since with jars on their heads. This first woman used another jar to cook food and another to serve it, and another to keep it clean and away from vermin and insects. Pray, what are millions of her great-grandchildren doing this very day but the selfsame things? It matters not who makes pottery, they are making it for women. Their convenience alone is consulted in its form, its temper and material. Its decorations are borrowed, and, tho her hands be no longer grimed with the paste, her wants and her imagination preside over the wheel.—MASON *Woman's Share in Primitive Culture,* ch. 5, p. 113. (A., 1894.)

2653. POVERTY AND THE STARS—*Enthusiasm for Science—A Life Course Changed.*—It was not without a struggle

that he [Bessel] resolved to exchange the desk for the telescope. His reputation with his employers was of the highest; he had thoroughly mastered the details of the business, which his keen, practical intelligence followed with lively interest; his years of apprenticeship were on the point of expiring, and an immediate and not unwelcome prospect of comparative affluence lay before him. The love of science, however, prevailed; he chose poverty and the stars, and went to Lilienthal with a salary of a hundred thalers yearly. Looking back over his life's work, Olbers long afterwards declared that the greatest service which he had rendered to astronomy was that of having discerned, directed, and promoted the genius of Bessel. —CLERKE *History of Astronomy*, pt. i, ch. 2, p. 36. (Bl., 1893.)

2654. POWER ACCOMPANIES COMPLEXITY—*Convolutions Few in Idiot's Brain —Reversion to Animal Type.*—Mr. Marshall has recently examined and described the brains of two idiots of European descent. He found the convolutions to be fewer in number, individually less complex, broader and smoother than in the apes. "In this respect," he says, "the idiots' brains are even more simple than that of the gibbon, and approach that of the baboon." The condition was the result neither of atrophy nor of mere arrest of growth, but consisted essentially in an imperfect evolution of the cerebral hemispheres or their parts, dependent on an arrest of development. The proportion of the weight of brain to that of body was extraordinarily diminished. We learn, then, that when man is born with a brain no higher—indeed, lower—than that of an ape, he may have the convolutions fewer in number, and individually less complex, than they are in the brain of a chimpanzee and an orang; the human brain may revert to or fall below that type of development from which, if the theory of Darwin be true, it has gradually ascended by evolution through the ages.—MAUDSLEY *Body and Mind*, lect. 2, p. 46. (A., 1898.)

2655. POWER, CONSTRUCTIVE, OF LOWER ORGANISMS—*Worms Build Tunnels Lined with Cement.*—The burrows [of earthworms] run down perpendicularly, or more commonly a little obliquely. . . . The walls of fresh burrows are often dotted with little globular pellets of voided earth, still soft and viscid, and these, as it appears, are spread out on all sides by the worm as it travels up or down its burrow. The lining thus formed becomes very compact and smooth when nearly dry, and closely fits the worm's body. The minute reflexed bristles which project in rows on all sides from the body thus have excellent points of support, and the burrow is rendered well adapted for the rapid movement of the animal. The lining appears also to strengthen the walls, and perhaps saves the worm's body from being scratched. I think so because several burrows which passed through a layer of sifted coal-cinders spread over turf to a thickness of 1½ inch, had been thus lined to an unusual thickness. In this case the worms, judging from the castings, had pushed the cinders away on all sides and had not swallowed any of them. In another place burrows similarly lined passed through a layer of coarse coal-cinders 3½ inches in thickness. We thus see that the burrows are not mere excavations, but may rather be compared with tunnels lined with cement. —DARWIN *Formation of Vegetable Mold*, ch. 2, p. 32. (Hum., 1887.)

2656. POWER, ECONOMY OF—*Automatic and Voluntary Actions of the Oyster.* —Look at the empty valve or shell from which you have just removed its tenant [the oyster]. You notice the oval impression on the inside of the valve showing where the muscle was attached, and you observe on the other and companion valve the neighbor impression. Between the two valves of the shell, then, there stretches this strong band of muscular fibers, so strong that it requires the deft hand of the oyster-opener to detach them. This muscle, which closes the valves and keeps them shut, is called the "abductor"; and while our oyster has but one, the mussels themselves possess two. It is a voluntary muscle this of the oyster, and quite as much at the command of the animal as your own biceps is placed under your behest.

But the abductor muscle of the oyster is not an organ which is frequently in use. If the shell is closed by its action, how, you inquire, are the valves opened? Look once again at the empty shell. You observe at its beak or apex the remains of a brownish substance. That is the "ligament" of the shell. It is an elastic band, which is put on the stretch when the shell is closed by the abductor muscle. If that muscle relaxes, you see what will happen. The elastic ligament will come into play, and by that elasticity will keep the shell open.

Now, as an open shell is the oyster's natural condition, we can note in this contrivance a saving of power. The shell is kept unclosed by the purely elastic and mechanical action of the ligament. The oyster has no need to bother itself over this duty. But it is when the more unusual work of closing the shell has to be accomplished that the vital and muscular act comes into play. Then the muscle acts, and "shuts up shop," so to speak, without delay. Nature is always economical in her distribution of power, and our oyster is kept gaping without the expenditure of any vital activity.—WILSON *Glimpses of Nature*, ch. 4, p. 18. (Hum., 1892.)

2657. POWER, ENORMOUS, STORED IN COAL—*Measured by Comparison with Human Labor.*—The most important source of mechanical power among those we have mentioned, and which promises almost to super-

sede all others, is that of burning coal. This material, like a watch wound up, is matter in a state of power, or in a state of unstable equilibrium, ready to rush into combination with the oxygen of the atmosphere as soon as the initial action is given, and to evolve power in the form of heat until the whole is consumed. It has been proved that on an average *four ounces* of coal is sufficient to draw, on a railway, one ton a mile. It has also been found by experiment that a man working on a tread-mill continuously for eight hours will elevate one and a half million of pounds one foot high. Now, good Cornish engines will perform the same work by the expenditure of the power of a pound and a half of coal. It follows from these data that about five tons of coal would evolve as much power during its combustion as would be equal to the continued labor of an able-bodied man for twenty years, at the rate of eight hours per day; or, in other words, to the average power of a man during the active period of his life. Providence has therefore stored away in the form of coal, for the use of man, an incalculable amount of mechanical power. Beneath the soil of our own great coal-basins there reposes power equivalent to the united force of myriads of giants, ready (like Aladdin's genius) to be called into activity by the lamp of science, and as its obedient slave to build cities, to transport palaces, or to remove mountains. There is no other locomotive power over which man has any prospect of control in the least degree comparable with this.—Henry *Improvement of the Mechanical Arts, Scientific Writings,* vol. i, p. 314. (Sm. Inst., 1886.)

2658. POWER, EXPULSIVE — *Comets Shot Forth from Stars—Proved by Parabolic Orbits.*—Every comet or meteor which follows a parabolic orbit possesses a velocity greater than that which the sun's attraction could give it, and it certainly enters the sphere of the solar attraction with a considerable original velocity. There is, then, no other way of explaining the interstellar velocities of comets and hyperbolic bolides but by tracing back their course to the time when their substance was projected from a star with a velocity exceeding by several miles per second that with which a body would reach that star if it had been drawn by gravity alone from an infinite distance.—Flammarion *Popular Astronomy,* bk. v, ch. 3, p. 527. (A.)

2659. POWER, IMPULSIVENESS A SOURCE OF — *Readiness and Promptness Achieve—Contrasted Advantages of the Reflective Character.*—As mental evolution goes on, the complexity of human consciousness grows ever greater, and with it the multiplication of the inhibitions to which every impulse is exposed. But this predominance of inhibition has a bad as well as a good side; and if a man's impulses are in the main orderly as well as prompt, if he has courage to accept their consequences, and intellect to lead them to a successful end, he is all the better for his hair-trigger organization, and for not being "sicklied o'er with the pale cast of thought." Many of the most successful military and revolutionary characters in history have belonged to this simple but quick-witted, impulsive type. Problems come much harder to reflective and inhibitive minds. They can, it is true, solve much vaster problems, and they can avoid many a mistake to which the men of impulse are exposed. But when the latter do not make mistakes, or when they are always able to retrieve them, theirs is one of the most engaging and indispensable of human types.—James *Psychology,* vol. ii, ch. 26, p. 538. (H. H. & Co., 1899.)

2660. POWER LOST IN TRANSMISSION—*Reflection of Light Only Partial.*—In all cases where the light is incident from air upon the surface of a solid or a liquid, or, more generally still, when the incidence is from a less highly refracting to a more highly refracting medium, the reflection is *partial.* In this case the most powerfully reflecting substances either transmit or absorb a portion of the incident light. At a perpendicular incidence water reflects only 18 rays out of every 1,000; glass reflects only 25 rays, while mercury reflects 666. When the rays strike the surface obliquely the reflection is augmented. At an incidence of 40°, for example, water reflects 22 rays, at 60° it reflects 65 rays, at 80° 333 rays; while at an incidence of 89½°, where the light almost grazes the surface, it reflects 721 rays out of every 1,000. Thus, as the obliquity increases, the reflection from water approaches and finally quite overtakes the reflection from mercury; but at no incidence, however great, when the incidence is from air, is the reflection from water, mercury, or any other substance *total.*—Tyndall *Lectures on Light,* lect. 1, p. 17. (A., 1898.)

2661. POWER, MECHANICAL, IN THE SUN'S RAYS — *The Noontide Sunshine of Manhattan Would Drive All the Engines of the World.*—From recent measures it appears that from every square yard of the earth exposed perpendicularly to the sun's rays, in the absence of an absorbing atmosphere, there could be derived more than one horse-power, if the heat were all converted into this use, and that even on such a little area as the island of Manhattan, or that occupied by the city of London, the noontide heat is enough, could it all be utilized, to drive all the steam-engines in the world. It will not be surprising, then, to hear that many practical men are turning their attention to this as a source of power, and that, tho it has hitherto cost more to utilize the power than it is worth, there is reason to believe that some of the greatest changes which civilization has to bring may

yet be due to such investigations.—LANGLEY *New Astronomy*, ch. 4, p. 111. (H. M. & Co., 1896.)

2662. POWER NOT PRODUCED BY MACHINE—*The Craze of Perpetual Motion.*—It was an old notion that power could be gained by machinery, and many men have spent years of time as well as fortunes in pursuing this will-o'-the-wisp, which, if true, would enable us to construct a machine that would propel itself. From their standpoint an animal or a man seemed to be a realization of a perpetual motion. They did not take into account the fact that the food which an animal eats and the air that it breathes sustain the relation, in a sense, to animal locomotion that coal burned under a boiler does to the propulsion of a steam-engine. In both cases there is oxidation caused by the union of oxygen with the carbon, the result of which is the production of heat. Many ingenious automatons were constructed that would simulate the movements of men and animals in the performance of certain kinds of work; and their ingenious constructors had in view the solution of a greater problem than that of the construction of a mere mechanical toy.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 2, p. 23. (F. H. & H., 1900.)

2663. POWER NOT PROPORTIONED TO SIZE—*Bacteria Inconceivably Minute.*—This [the coccus] is the group of round cells They vary in size as regards species and as regards the conditions, artificial or natural, under which they have been grown. Some are less than $\frac{1}{15000}$ of an inch in diameter; others are half as large again, if the word "large" may be used to describe such minute objects. No regular standard can be laid down as reliable with regard to their size. Hence the subdivisions of the cocci are dependent not upon the individual elements so much as upon the relation of those elements to each other.—NEWMAN *Bacteria*, ch. 1, p. 8. (G. P. P., 1899.)

2664. POWER OF ADAPTATION—*What is a "Common Plant"?*—"What," said Professor Lindley, fifty years ago, "is a 'common' plant but one which can grow and propagate itself in almost any kind of soil, and under almost every range of temperature; and what is a 'rare' plant but one which cannot flourish and produce seed, except under certain special conditions?" Every botanist knows that among our own wild plants, *Rosa*, *Rubus*, and *Salix* are alike the most "variable" and the most "common" types; "common," because they have the capacity for adapting themselves to different conditions of growth; "variable," because of the influence of those varying conditions upon their organization. Out of the forms of rose, bramble, and willow, ranked as "varietal" by Mr. Bentham, our ablest student of them, previous systematists had created more than three hundred "species."—CARPENTER *Nature and Man*, lect. 15, p. 437. (A., 1889.)

2665. POWER OF A GREAT TEACHER—*Work of Agassiz in America—Influence Long Enduring.*—With the possible exception of the elder Silliman, the influence of Louis Agassiz on the development of science in our country has been greater than that of any other single man. . . . The son of a Protestant clergyman, he was born in Switzerland in 1807, and his early academic education was obtained in Bienne, Lausanne, and Zurich, whence he passed to the great German universities of Heidelberg, Munich, and Erlangen. Even in those days he was a leader. . . . In 1846 an invitation to deliver a course of lectures before the Lowell Institute in Boston was obtained for him through the interest of his friend, Sir Charles Lyell, and he agreed, with Mr. John A. Lowell, to give a course of lectures on the "Plan of the Creation," especially in the animal kingdom. He arrived in Boston in October, and in December delivered his first lecture. "He carried his audience captive." . . . Enthusiastic audiences greeted him in New York, Philadelphia, Charleston, and elsewhere, and yielding to the irresistible opportunities offered to him he severed the ties that bound him to the land of his birth, and accepted the chair of zoology and geology in the Lawrence Scientific School.

Guyot, his friend from boyhood, in speaking of the immense power he exerted in this country in spreading the taste for natural science and elevating the standard, says:

"How many leading students of Nature are found to call themselves his pupils, and gratefully acknowledge their great indebtedness to his judicious training? How many who now occupy scientific chairs in our public institutions multiply his influence by inculcating his methods, thus rendering future success sure."

In this connection I want to quote from a letter of one of his students who wrote me concerning his teaching as follows:

"The ideal of a young scientific student, and of every great teacher, is a devotion to scientific research for its own sake. Agassiz had that ideal extraordinarily developed, and on that account the student was drawn to him and felt in a corresponding degree a great influence on his life. Agassiz made many and important contributions to science, but the greatest of all was a life which embodied the ideal that scientific research is an unselfish study of truth for truth's sake. Every student who was brought in contact with Agassiz recognized this ideal, and was profoundly influenced by it."

The Museum of Comparative Zoology in Cambridge is his most conspicuous monument, but his influence, more powerful than bricks or mortar, will live forever.

A boulder from the glacier of the Aar marks his last resting-place in Mount Au-

burn, and so "the land of his birth and the land of his adoption are united in his grave." — MARCUS BENJAMIN *Early Presidents of the American Association (Proceedings of Amer. Assoc. for the Advancement of Science, 1899).*

2666. POWER OF AIR-CURRENTS—*Birds and Insects Blown off Shore—Insects Borne to Mountain-tops.*—Small singing birds, and even butterflies (as I have myself witnessed in the Pacific), are often met with at great distances from the shore during storms blowing off land. In a similar manner insects are involuntarily carried into the higher regions of the atmosphere, to an elevation of 17,000 to 19,000 feet above the plains. The light bodies of these insects are borne upwards by the vertically ascending currents of air caused by the heated condition of the earth's surface. M. Boussingault, an admirable chemist, who ascended the Gneiss Mountains of Caracas, while holding the appointment of Professor in the newly established Mining Academy at Santa Fé de Bogotá, witnessed, during his ascent to the summit of the Silla, a phenomenon which confirmed in a most remarkable manner this vertical ascent of air. He and his companion, Don Mariano de Rivero, observed at noon a number of luminous, whitish bodies rise from the valley of Caracas to the summit of the Silla, an elevation of 5,755 feet, and then sink towards the adjacent seacoast. This phenomenon was uninterruptedly prolonged for a whole hour, when it was discovered that the bodies, at first mistaken for a flock of small birds, were a number of minute balls of grass-haulm. Boussingault sent me some of this grass, which was immediately recognized by Professor Kunth as a species of *Vilfa.*—HUMBOLDT *Views of Nature*, p. 232. (Bell, 1896.)

2667. POWER OF CONTROLLED INTENSITY—*Impulsiveness Easy.*—The highest form of character, however, abstractly considered, must be full of scruples and inhibitions. But action, in such a character, far from being paralyzed, will succeed in energetically keeping on its way, sometimes overpowering the resistances, sometimes steering along the line where they lie thinnest. . . . The mind of him whose fields of consciousness are complex, and who, with the reasons for the action, sees the reasons against it, and yet, instead of being palsied, acts in the way that takes the whole field into consideration—such a mind is the ideal sort of mind that we should seek to reproduce in our pupils. Purely impulsive action, or action that proceeds to extremities regardless of consequences, on the other hand, is the easiest action in the world and the lowest in type. —JAMES *Talks to Teachers*, ch. 15, p. 179. (H. H. & Co., 1900.)

2668. POWER OF ELEMENTAL FORCES — *Nature's Glassmaking — Fulgurites — Man's Imitations Feeble.*—In a broad band of sand-hillocks [near the Rio Plata] . . . I found a group of those vitrified, siliceous tubes which are formed by lightning entering loose sand. These tubes resemble in every particular those from Drigg, in Cumberland, . . . one of which was traced to a depth of not less than thirty feet. The internal surface is completely vitrified, glossy, and smooth. . . . Their circumference is about two inches, but in some fragments, which are cylindrical and without any furrows, it is as much as four inches. . . . At Paris M. Hachette and M. Beudant succeeded in making tubes, in most respects similar to these fulgurites, by passing very strong shocks of galvanism through finely-powdered glass. . . . One tube, formed with pounded glass, was very nearly an inch long, namely, .982, and had an internal diameter of .019 of an inch. When we hear that the strongest battery in Paris was used, and that its power on a substance of such easy fusibility as glass was to form tubes so diminutive, we must feel greatly astonished at the force of a shock of lightning which, striking the sand in several places, has formed cylinders, in one instance of at least thirty feet long, and having an internal bore, where not compressed, of full an inch and a half; and this in a material so extraordinarily refractory as quartz!—DARWIN *Naturalist's Voyage around the World*, ch. 3, p. 58. (A., 1898.)

2669. POWER OF EVIL DEPENDENT ON WHAT IT FINDS—*Bacteria Produce Disease in Disordered System.*—It has been known for some time past that not all waters polluted with disease-germs produce disease. . . . This may depend upon the infective agent, its quantity and quality, the body being able in many cases to resist a small dose of poison. It is, however, necessary to infection, especially in water-borne disease, that the tissues shall be in some degree disordered. The perverted action of the stomach influences the acid secretion of the gastric juice, through which bacilli might then pass uninjured. Particularly must this be so in the bacillus of cholera, which is readily killed by the normal acid reaction of the stomach.—NEWMAN *Bacteria*, ch. 2, p. 83. (G. P. P., 1899.)

2670. POWER OF EXPANSION—*Bunker Hill Monument Bent by Sunshine.*—Every day when the sun shines the top of Bunker Hill monument is thrown out of plumb several inches by the power of expansion. The same is true of any tower or shaft constructed in the same way. The side that the sun's rays fall upon is expanded, while the opposite remains practically the same. All the molecules on the sunny side are thrown into greater activity, and . require more space in which to move. This causes the column to bend away from the sun in the form of a curve.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 14, p. 120. (F. H. & H., 1900.)

2671. POWER OF EXPECTANT ATTENTION—*Officer Awakes at the Word "Signal."*—The following remarkable example . . . was mentioned to the writer by the late Sir Edward Codrington:

When a young man, he was serving as signal-lieutenant under Lord Hood at the time of the investment of Toulon; and being desirous of obtaining the favorable notice of his commander, he applied himself to his duty—that of watching for signals made by the "lookout" frigates—with such energy and perseverance that he often remained on deck eighteen or nineteen hours out of the twenty-four, going below only to sleep. During the few hours which he spent in repose his slumber was so profound that no noise of an ordinary kind, however loud, would awake him, and it used to be a favorite amusement with his comrades to try various experiments devised to test the soundness of his sleep. But if the word "signal" was even whispered in his ear he was instantly aroused, and was fit for immediate duty, the constant direction of his mind towards this one object having given to the impression produced by the softest mention of its name a power over his brain which no other could exert.

It seems impossible to account for these facts in any other way than by attributing to the nerve-centers a peculiar physical receptivity for impressions of some particular class, which they have acquired in virtue of the previous direction of the mind to them. —CARPENTER *Mental Physiology*, bk. ii, ch. 15, p. 582. (A., 1900.)

2672. POWER OF FLIGHT LOST BY DISUSE—*Wingless Moths, Flies, and Beetles.* —Kerguelen Island . . . was visited by the transit of Venus expedition. It is one of the stormiest places on the globe, being subject to almost perpetual gales, while, there being no wood, it is almost entirely without shelter. The Rev. A. E. Eaton, an experienced entomologist, was naturalist to the expedition, and he assiduously collected the few insects that were to be found. All were incapable of flight, and most of them entirely without wings. They included a moth, several flies, and numerous beetles. As these insects could hardly have reached the islands in a wingless state, even if there were any other known land inhabited by them—which there is not—we must assume that . . . they were originally winged, and lost their power of flight because its possession was injurious to them.—WALLACE *Darwinism*, ch. 5, p. 74. (Hum.)

2673. POWER OF GOOD INVOLVES CAPACITY OF FAILURE—*The Automaton Sure, but Helpless.*—A high brain may do many things, and may do each of them at a very slight hint. But its hair-trigger organization makes of it a happy-go-lucky, hit-or-miss affair. It is as likely to do the crazy as the sane thing at any given moment. A low brain does few things, and in doing them perfectly forfeits all other use. —JAMES *Psychology*, vol. i, ch. 5, p. 140. (H. H. & Co., 1899.)

2674. POWER OF GROWTH—*Growing Root Divides Earth, as Wooden Wedge Splits Rock.*—With these facts before us, there seems little difficulty in understanding how a radicle penetrates the ground. The apex is pointed and is protected by the root-cap; the terminal growing part is rigid and increases in length with a force equal, as far as our observations can be trusted, to the pressure of at least a quarter of a pound, probably with a much greater force when prevented from bending to any side by the surrounding earth. Whilst thus increasing in length it increases in thickness, pushing away the damp earth on all sides, with a force of above 8 pounds in one case, of 3 pounds in another case. It was impossible to decide whether the actual apex exerts, relatively to its diameter, the same transverse strain as the parts a little higher up; but there seems no reason to doubt that this would be the case. The growing part, therefore, does not act like a nail when hammered into a board, but more like a wedge of wood, which whilst slowly driven into a crevice continually expands at the same time by the absorption of water; and a wedge thus acting will split even a mass of rock.—DARWIN *Power of Movement in Plants*, ch. 2, p. 78. (A., 1900.)

2675. POWER OF HABIT—*Automatic Action—Without Reflection or Even Consciousness Accomplishes the Ends of Volition.*—Actions originally prompted by conscious intelligence may grow so automatic by dint of habit as to be apparently unconsciously performed. Standing, walking, buttoning and unbuttoning, piano-playing, talking, even saying one's prayers, may be done when the mind is absorbed in other things. The performances of animal *instinct* seem semi-automatic, and the *reflex acts* of self-preservation certainly are so. Yet they resemble intelligent acts in bringing about the *same ends* at which the animal's consciousness, on other occasions, deliberately aims.—JAMES *Psychology*, vol. i, ch. 1, p. 5. (H. H. & Co., 1899.)

2676. POWER OF HIGHER FACULTIES—*More Persistent than That of Lower—Intellect Rallies from Shock before Sense-perception.*—Under ordinary circumstances the discharge from a small Leyden jar is exceedingly unpleasant to me. Some time ago I happened to stand in the presence of a numerous audience, with a battery of fifteen large Leyden jars charged beside me. Through some awkwardness on my part I touched a wire leading from the battery, and the discharge went through my body. Life was absolutely blotted out for a very sensible interval, without a trace of pain. In a second or so consciousness returned;

I vaguely discerned the audience and apparatus, and by the help of these external appearances immediately concluded that I had received the battery discharge. The *intellectual* consciousness of my position was restored with exceeding rapidity, but not so the *optical* consciousness. To prevent the audience from being alarmed I observed that it had often been my desire to receive accidentally such a shock, and that my wish had at length been fulfilled. But while making this remark the appearance which my body presented to my eyes was that of a number of separate pieces. The arms, for example, were detached from the trunk, and seemed suspended in the air. In fact, memory and the power of reasoning appeared to be complete long before the optic nerve was restored to healthy action.—TYNDALL *Fragments of Science*, vol. i, ch. 21, p. 442. (A., 1900.)

2677. POWER OF MIND OVER BODY—*Pain from Imaginary Wound.*—"A butcher was brought into the shop of Mr. Macfarlan, the druggist, from the market-place opposite, laboring under a terrible accident. The man, on trying to hook up a heavy piece of meat above his head, slipped, and the sharp hook penetrated his arm, so that he himself was suspended. On being examined he was pale, almost pulseless, and expressed himself as suffering acute agony. The arm could not be moved without causing excessive pain, and in cutting off the sleeve he frequently cried out; yet when the arm was exposed, it was found to be quite uninjured, the hook having only traversed the sleeve of his coat."—BENNET *The Mesmeric Mania of 1851*, quoted by CARPENTER in *Nature and Man*, bk. i, ch. 4, p. 158. (A., 1900.)

2678. POWER OF MUSCLES INSTANTLY AVAILABLE—*Tension Maintained in Rest.*—During rest or inactivity a muscle has a slight but very perfect elasticity; it admits of being considerably stretched, but returns readily and completely to its normal length. In the living body the muscles are always stretched somewhat beyond their natural length; they are always in a condition of slight tension, an arrangement which enables the whole force of the contraction to be utilized in approximating the points of attachment. It is obvious that if the muscles were lax the first part of the contraction till the muscle became tight would be wasted.—BAKER *Handbook of Physiology*, vol. ii, ch. 15, p. 22. (W. W., 1885.)

2679. POWER OF QUIET PROCESS—*Simmering Water Cooks Food Effectually.*—As a medium for heating the substances to be cooked, simmering water is just as effective as "walloping" water. There are exceptional operations of cookery, wherein useful mechanical work is done by violent boiling; but in all ordinary cookery simmering is just as effective. The heat that is applied to do more than the smallest degree of simmering is simply wasted in converting water into useless steam. The amount of such waste may be easily estimated. To raise a given quantity of water from the freezing- to the boiling-point demands an amount of heat represented by 180° in Fahrenheit's thermometer, or 100° centigrade. To convert this into steam 990° F., or 550° C., is necessary—just five and a half times as much.—WILLIAMS *Chemistry of Cookery*, ch. 2, p. 15. (A., 1900.)

2680. ——— ——— *The Spring vs. the Volcano.*—Altho the violent and paroxysmal outbursts of volcanic mountains arrest the attention, and powerfully impress us with a sense of the volcanic activity going on beneath the earth's surface, yet it may well be doubted whether the quantity of heat which the earth gets rid of by their means at all approaches in amount that which is quietly dissipated by means of the numerous "stufas," gaseous exhalations, and thermal springs which occur in such abundance all over its surface. For while the former are intermittent in their action, and powerful outbursts are interrupted by long periods of rest, the action of the latter, tho feeble, is usually continuous.—JUDD *Volcanoes*, ch. 8, p. 218. (A., 1899.)

2681. POWER OF SLOW-MOVING MASS—*Glacier Plows Away Hill.*—The snout of a glacier is potent to remove anything against which it can fairly abut; and this power, notwithstanding the slowness of the motion, manifests itself at the end of the Morteratsch glacier. A hillock, bearing pine-trees, was in front of the glacier when Mr. Hirst and myself inspected its end, and this hillock is being bodily removed by the thrust of the ice. Several of the trees are overturned, and in a few years, if the glacier continues its reputed advance, the mound will certainly be plowed away.—TYNDALL *Fragments of Science*, ch. 9, p. 249. (A., 1897.)

2682. POWER OF THE INVISIBLE—*Energy of Molecules—Their Rebound Turns the Radiometer.*—The radiometer, to be seen in almost every optician's window, was invented by Sir William Crookes in 1873, and consists of an exceedingly delicate windmill, formed of four very slender arms supporting thin metal or pith disks, one side of which is blackened, the whole turning on a fine central point, so as to revolve with hardly any friction. The little machine is enclosed in a glass bulb from which nearly all the air has been extracted; and when exposed to the sun, or even to diffused daylight, the disks revolve with considerable speed. At first this motion was supposed to be caused by the direct impact of the rays of light, the almost complete vacuum only serving to diminish friction; but the explanation now generally adopted is that the black surfaces of the vanes, absorbing heat, become slightly

warmer than the white surfaces, and this greater warmth is communicated to the air-molecules, and causes them to rebound with greater rapidity from the dark surfaces and back again from the glass of the vessel, and the reaction, being all in one direction, causes the arms to revolve. The near approach to a vacuum is necessary, both to diminish resistance, and by greatly reducing the number of molecules in the vessel, to allow the very small differential action to produce a sensible effect. Sir William Crookes has found that there is a degree of rarefaction where the action is at a maximum, and that when a nearer approach to a perfect vacuum is attained the motion rapidly diminishes. A proof is thus given of the correctness of the explanation, and the instrument may, therefore, be considered to afford us an experimental illustration of the molecular theory of gases.—WALLACE *The Wonderful Century*, ch. 8, p. 59. (D. M. & Co., 1899.)

2683. ——— ——— *Heat-waves Contrasted with Rays of Light.*—Besides those which produce light, the sun sends forth incessantly a multitude of waves which produce no light. The largest waves which the sun sends forth are of this non-luminous character, tho they possess the highest heating power.

A common sunbeam contains waves of all kinds, but it is possible to sift or filter the beam so as to intercept all its light, and to allow its obscure heat to pass unimpeded. For substances have been discovered which, while intensely opaque to the light-waves, are almost perfectly transparent to the others. On the other hand, it is possible, by the choice of proper substances, to intercept in a great degree the pure heat-waves, and to allow the pure light-waves free transmission. . . . Supposing, then, that we withdraw, in the first instance, the large heat-waves and allow the light-waves alone to pass. These may be concentrated by suitable lenses and sent into water without sensibly warming it. Let the light-waves now be withdrawn and the larger heat-waves concentrated in the same manner; they may be caused to boil the water almost instantaneously. . . . The light-waves, even when concentrated to the uttermost, are unable to melt the most delicate hoar-frost.—TYNDALL *Forms of Water*, p. 12. (A., 1899.)

2684. ——— ——— *The Sun's Attractive Energy.*—The sun, besides sustaining us by his light-giving and heat-supplying powers, keeps us always near to him by that mighty force of attraction which his vast bulk enables him to exert. When we look at the sun as he rises (even as "the glory of God coming from the way of the east") how seldom is the thought present in our minds that in that ruddy orb there exists the most tremendous power, swaying not only this vast globe on which we live, but orbs yet vaster than she is and traveling on far wider courses.—PROCTOR *Expanse of Heaven*, ch. 2, p. 13. (L. G. & Co., 1897.)

2685. ——— ——— *Transporting Action of the Wind—Granite Cliffs Blown Away.*—The transporting action of the wind, or "deflation," as it is termed, goes on without ceasing day and night and during all seasons; and the result is seen in the deeply eroded rocks, enormous masses of which, it can be shown, have been thus gradually removed. The evidence of denudation is conspicuous, but its products have for the most part been carried away. In some places, as Professor Walther remarks of the Libyan Desert, are great walls of granite rising to heights of 6,000 feet, but showing no slopes of débris below, as would infallibly be present under temperate conditions of climate. In other places, again, are deeply excavated wadies containing no beds of gravel, grit, and sand, such as would not fail to show themselves had the depressions in question been formed by water-action alone. Everywhere deep, cavelike hollows have been worn out in the rocks, and yet these hold no sediment or detritus, but are swept bare. The wind tends, in short, to transport all loose material from the scene of its origin to the borders of the desert.—GEIKIE *Earth Sculpture*, ch. 2, p. 24. (G. P. P., 1898.)

2686. ——— ——— *Unseen Rays of Spectrum Rich in Heat.*—The great pioneer in this domain of science [the study of radiation] was Sir William Herschel. Causing a beam of solar light to pass through a prism, he resolved it into its colored constituents; he formed what is technically called the solar spectrum. Exposing thermometers to the successive colors, he determined their heating power, and found it to augment from the violet or most refracted end to the red or least refracted end of the spectrum. But he did not stop here. Pushing his thermometers into the dark space beyond the red, he found that, tho the light had disappeared, the radiant heat falling on the instruments was more intense than that at any visible part of the spectrum. In fact, Sir William Herschel showed, and his results have been verified by various philosophers since his time, that, besides its luminous rays, the sun pours forth a multitude of other rays, more powerfully calorific than the luminous ones, but entirely unsuited to the purposes of vision.—TYNDALL *Fragments of Science*, ch. 2, p. 32. (A., 1897.)

2687. ——— ——— *Unseen Rays of Spectrum Yield Chemical Energy, as Well as Heat.*—At the less refrangible end of the solar spectrum, then, the range of the sun's radiation is not limited by that of the eye. The same statement applies to the more refrangible end. Ritter discovered the extension of the spectrum into the invisible region beyond the violet, and in recent times this

ultraviolet emission has had peculiar interest conferred upon it by the admirable researches of Professor Stokes. The complete spectrum of the sun consists, therefore, of three distinct parts: first, of ultrared rays of high heating power, but unsuited to the purposes of vision; secondly, of luminous rays which display the succession of colors, red, orange, yellow, green, blue, indigo, violet; thirdly, of ultraviolet rays which, like the ultrared ones, are incompetent to excite vision, but which, unlike the ultrared rays, possess a very feeble heating power. In consequence, however, of their chemical energy these ultraviolet rays are of the utmost importance to the organic world.—TYNDALL *Fragments of Science*, ch. 2, p. 32, (A., 1897.)

2688. POWER OF THE SUN—*Greater than the Conjectures of Its Ancient Worshipers.*—At the return of the equinox the rising of the sun, the god of day, the king of light, was saluted by the Incas from the heights of their cyclopean terraces. The same adoration, the same worship, is met with among all the ancient peoples. Without yet taking into account the real size and the incomparable importance of the dazzling star, they already knew that he is the father of terrestrial Nature; they knew that it is his heat which supports life; they knew that it is he who makes the trees in the forests to grow, the stream to flow in the valley, the flowers of the meadow to bloom, the bird to sing in the wood, the cereals and the vines to ripen, and they hailed in him their father, their friend, and their protector.

Modern science has not only confirmed but increased tenfold, a hundredfold, the ancient conjectures. The sun's light, heat, and power are as much above the ancient ideas as the poetry of Nature is above our interpretation. No light created by human industry can be compared with his. Interposed before his disk, the brilliant electric light appears black. The highest temperatures of our furnaces, that of the melting of gold, of silver, of platinum, of iron, are but ice compared with the solar heat.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 3, p. 243. (A.)

2689. POWER OF TWINING OR CLIMBING INNATE—*Wonderful Adaptations.*—That the movements of climbing plants consist of ordinary circumnutation, modified by being increased in amplitude, is well exhibited whilst the plants are very young; for at this early age they move like other seedlings, but as they grow older their movements gradually increase without undergoing any other change. That this power is innate, and is not excited by any external agencies, beyond those necessary for growth and vigor, is obvious. No one doubts that this power has been gained for the sake of enabling climbing plants to ascend to a height, and thus to reach the light. This is effected by two very different methods—first by twining spirally round a support, but to do so their stems must be long and flexible; and secondly, in the case of leaf-climbers and tendril-bearers, by bringing these organs into contact with a support, which is then seized by the aid of their sensitiveness. It may be here remarked that these latter movements have no relation, as far as we can judge, with circumnutation. In other cases the tips of tendrils, after having been brought into contact with a support, become developed into little disks which adhere firmly to it.—DARWIN *Power of Movement in Plants*, ch. 5, p. 267. (A., 1900.)

2690. POWER OF UNAIDED VISION—*May Even Surpass Telescope—Visibility of Distant Objects—White on Black More Distinct than Black on White.*—During my visit at a charming country-seat . . . not far from Quito, where the long-extended crests of the volcano of Pichincha lay stretched before me at a horizontal distance trigonometrically determined at more than 90,000 feet, I was much struck by the circumstance that the Indians who were standing near me distinguished the figure of my traveling companion Bonpland (who was engaged in an expedition to the volcano) as a white point moving on the black basaltic sides of the rock, sooner than we could discover him with our telescopes. The white moving image was soon detected with the naked eye both by myself and by my friend. . . . Bonpland was enveloped in a white cotton mantle, the poncho of the country; assuming the breadth across the shoulders to vary from three to five feet, according as the mantle clung to the figure or fluttered in the breeze, and judging from the known distance, we found that the angle at which the moving object could be distinctly seen varied from 7″ to 12″. White objects on a black ground are, according to Hueck's repeated experiments, distinguished at a greater distance than black objects on a white ground. . . . Gauss's heliotrope light, which has become so important an element in German trigonometrical measurements, has been seen with the naked eye reflected from the Brocken on Hohenhagen, at a distance of about 227,000 feet, or more than 42 miles.—HUMBOLDT *Cosmos*, vol. iii, p. 55. (H., 1897.)

2691. POWER, PHILOSOPHIC, COMBINED WITH MEMORY—If . . . we consider the brain to be the organic condition by which the vestiges of our experience are associated with each other, we may suppose that some brains are "wax to receive and marble to retain." The slightest impressions made on them abide. Names, dates, prices, anecdotes, quotations, are indelibly retained, their several elements fixedly cohering together, so that the individual soon becomes a walking cyclopedia of information. . . . And when both memory

and philosophy combine together in one person, then, indeed, we have the highest sort of intellectual efficiency. Your Walter Scotts, your Leibnitzes, your Gladstones, and your Goethes, all your folio copies of mankind, belong to this type. Efficiency on a colossal scale would indeed seem to require it. For, altho your philosophic or systematic mind without good, desultory memory may know how to work out results and recollect where in the books to find them, the time lost in the searching process handicaps the thinker, and gives to the more ready type of individual the economical advantage.—JAMES *Talks to Teachers*, ch. 12, p. 120. (H. H. & Co., 1900.)

2692. POWER STORED IN COAL-FIELDS—*Millions of Horses Could Not Equal.*—We dig annually 84 millions of tons of coal from our pits. The amount of mechanical force represented by this quantity of coal seems perfectly fabulous. The combustion of a single pound of coal, supposing it to take place in a minute, would be equivalent to the work of 300 horses; and if we suppose 108 millions of horses working day and night with unimpaired strength for a year, their united energies would enable them to perform an amount of work just equivalent to that which the annual produce of our coal-fields would be able to accomplish.—TYNDALL *Fragments of Science*, vol. i, ch. 16, p. 373. (A., 1897.)

2693. POWER UNDESIRABLE WITHOUT BENEFICENCE—A cold and inert mass of matter, however, would be able to do all that the sun does by his mere mass, and yet be utterly unfit to be, like him, the ruler over a scheme of circling worlds. The glory of the sun is not in his strength alone. As Sir John Herschel has well said, "Giant size and giant strength are ugly qualities without beneficence." But the sun is the almoner of the Almighty, the delegated dispenser to us of light and warmth, as well as the center of attraction.—PROCTOR *Expanse of Heaven*, ch. 2, p. 15. (L. G. & Co., 1897.)

2694. POWERS, MECHANICAL, ALL USED BY PRIMITIVE MAN—The mechanical powers, in the order of their simplicity, are the *inclined plane*, the *wedge*, *lever*, the *roller*, the *pulley*, the *wheel and axle*, and the *screw*. These devices for converting time and weight and velocity into momentum, and for changing the direction and character of momentum, are at the foundation of the modern intricate machinery. But the simplest forms of all these useful things were elaborated by primitive mechanics with what little suggestion they could get from the animal world. The inclined plane, both for rolling and sliding friction, as well as for convenience in walking, is too easy to dwell upon. The Eskimo sledge men, the hunter dragging his game, the fishermen on a sloping beach landing a great sea monster or a canoe, the Indians of the cañons making a trail, the Caribs launching a pirogue, the mound-builders or the Mexicans ascending a great ceremonial earthwork, were equally skilled in selecting a gentle slope or in making one. The natives of British Columbia make skids of stout saplings, and on them roll up the logs that are to form the plate pieces of their communal dwellings, holding them in position by means of shore poles. The great stone buildings of Mexico, Central America, and Peru were the work of men's hands, with no aid from animals or natural powers. The invariable association of all such structures with sloping earthworks and pyramids points to the chief mechanical power known to the builders. An additional value is given to the inclined plane in that it allows the cooperation of as many individuals as are necessary, and it also lends itself to cooperation with the other powers. The wedge was in universal use among the American native mechanics. . . . The wedges were always made of the hardest material known in any region. Wood, ivory, elkhorn, bone, and even hammered copper did service.—MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology*, p. 74). (Sch. P. C.)

2695. POWERS, MECHANICAL, ANTEDATE HISTORY—*The Lever, Roller, Inclined Plane, and Pulley Known in Ancient Egypt.*—As to how simple mechanical powers were first learned, it is of no use to guess in what rude and early age men found that stones or blocks too weighty to lift by hand could be prized up and moved along with a stout stick, or rolled on two or three round poles, or got up a long, gentle slope more easily than up a short, steep rise. Thus such discoveries as those of the lever, roller, and inclined plane are quite out of historical reach. The ancient Egyptians used wedges to split off their huge blocks of stone, and one wonders that, knowing the pulleys as they did, it never appears in the rigging of their ships. . . . A draw-well, with a pulley, is to be seen in the Assyrian sculptures, where also a huge winged bull is being heaved along with levers, and dragged on a sledge with rollers laid underneath.—TYLOR *Anthropology*, ch. 8, p. 198. (A., 1899.)

2696. POWERS, UNUSED, PERISH—*The Eyes of the Mole Atrophied—Blind Fishes in Caves.*—There are certain burrowing animals—the mole, for instance—which have taken to spending their lives beneath the surface of the ground. And Nature has taken her revenge upon them in a thoroughly natural way—she has closed up their eyes. If they mean to live in darkness, she argues, eyes are obviously a superfluous function. By neglecting them these animals made it clear they do not want them. And as one of Nature's fixed principles is that nothing shall exist in vain, the eyes are presently taken away, or re-

duced to a rudimentary state. There are fishes also which have had to pay the same terrible forfeit for having made their abode in dark caverns, where eyes can never be required. And in exactly the same way the spiritual eye must die and lose its power by purely natural law if the soul choose to walk in darkness rather than in light.—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 99. (H. Al.)

2697. PRACTISE, EFFECT OF—*Machine Runs More Easily by Use—Exertion Secures Increased Supply—Nerve Stimulation More Readily Set Up.*—A movement which takes place again and again in the same direction comes by degrees to follow this direction more readily than any other, and will presently be unaffected by influences which at first would have had no difficulty in diverting it. When water is poured upon the ground it forms a channel for itself. Its initial direction may have been determined by the merest accident, but, once determined, is adhered to, and the more certainly the oftener we pour. When a machine is set in motion there is always the same resistance of mass to be overcome in its various parts; but friction is lessened by the wearing and smoothing of part against part, so that a machine which has been going for some time usually runs more easily than a new one or one which has lain for a long time unused. If you let your watch run down, and do not wind it up for a fortnight, you know that it is always liable to stop until it has been going again for a week or so. Now there is good evidence for the view that the same thing holds of neural processes. If we are in the habit of executing some definite muscular movement we know that it gradually becomes easier—*i. e.*, can be made with less expenditure of force. What we call "practise" consists simply in changes of this sort. The execution of a practised movement becomes easier because the stimulation-process in nerve and muscle is the more easily set up the more frequently it is repeated. This process is originated by an increased supply of the elements essential to the tissues; so that exercised muscles show an increase in the mass of their contractile substance.—WUNDT *Psychology*, lect. 9, p. 144. (Son. & Co., 1896.)

2698. PRACTISE MUST BE SUPPORTED BY THEORY—*Closet Workers Needful to Sustain Industrial Achievement.*—To keep society as regards science in healthy play, three classes of workers are necessary: Firstly, the investigator of natural truth, whose vocation it is to pursue that truth, and extend the field of discovery for the truth's own sake, and without reference to practical ends. Secondly, the teacher of natural truth, whose vocation it is to give public diffusion to the knowledge already won by the discoverer. Thirdly, the applier of natural truth, whose vocation it is to make scientific knowledge available for the needs, comforts, and luxuries of civilized life. These three classes ought to coexist and interact. Now, the popular notion of science, both in this country and in England, often relates not to science strictly so called, but to the applications of science. Such applications, especially on this continent, are so astounding—they spread themselves so largely and umbrageously before the public eye—that they often shut out from view those workers who are engaged in the quieter and profounder business of original investigation.—TYNDALL *Lectures on Light*, lect. 6, p. 219. (A., 1898.)

2699. PRACTISE TRANSFORMS VOLUNTARY INTO AUTOMATIC MOVEMENT—Practise always implies that an action which at first was performed voluntarily has gradually become reflex and automatic. Thus when the child learns to walk, the taking of each single step is accompanied by a considerable effort of will; but after a time and by slow degrees it becomes able to initiate a whole series of movements without attending to their execution in detail. In the same way we learn to play the pianoforte or to execute other complicated movements of the hands by frequent repetition of particular and connected acts, and their consequent transformation into a chain of effects which follow each other with mechanical certainty when once the appropriate impulse has been given. Now the modifications which the nervous system undergoes during the life of the individual, in consequence of the mechanizing of these practised movements, must naturally, like all other modifications of the same kind, be summated and intensified in the course of generations. The purposive character of the reflexes becomes then readily intelligible, if we regard them as resulting from the voluntary action of previous generations.—WUNDT *Psychology*, lect. 15, p. 227. (Son. & Co., 1896.)

2700. PRAYER A UNIVERSAL IMPULSE—*Will Persist Spite of All Discussion.*—We hear, in these days of scientific enlightenment, a great deal of discussion about the efficacy of prayer; and many reasons are given us why we should not pray, whilst others are given us why we should. But in all this very little is said of the reason why we *do* pray, which is simply that we cannot *help* praying. It seems probable that, in spite of all that "science" may do to the contrary, men will continue to pray to the end of time, unless their mental nature changes in a manner which nothing we know should lead us to expect. The impulse to pray is a necessary consequence of the fact that whilst the innermost of the empirical selves of a man is a self of the *social* sort, it yet can find its only adequate *socius* in an ideal world.—JAMES *Psychology*, vol. i, ch. 10, p. 316. (H. H. & Co., 1899.)

2701. PRAYER CANNOT BENEFIT BY FALSE PRETENSE—*Preaching to Oneself under Guise of Praying to God.*—We find many men now facing the consequences to which they have given their intellectual assent, and taking their stand upon the ground that prayer to God has no other value or effect than so far as it may be a good way of preaching to ourselves. It is a useful and helpful exercise for our own spirits, but it is nothing more. But how can they pray who have come to this? Can it ever be useful or helpful to believe a lie? That which has been threatened as the worst of all spiritual evils would then become the conscious attitude of our "religion," the habitual condition of our worship. This must be a bad science, as it is bad religion. It is in violation of a law the highest known to man—the law which inseparably connects earnest conviction of the truth in what we do or say with the very fountains of all intellectual and moral strength. No accession of force can come to us from doing anything in which we disbelieve.—ARGYLL *Reign of Law*, ch. 2, p. 37. (Burt.)

2702. PRECESSION OF THE EQUINOXES—*Changes Wrought during That Long Duration—Transitoriness of Human Life—The Transforming Work of Time.*—Immense and slow revolution of the skies! What events occur on our globe during the course of one of these periods! The last time that the pole occupied the place which it does today, 25,765 years ago, none of the present countries existed. None of the nations who dispute to-day for supremacy on the planet had then left the cradle of Nature. Already, doubtless, there were men upon the earth, but the social unions which they formed have left no trace of the degree of civilization to which they had attained, and it is very probable that these uncultured and savage beings were then in the midst of the primitive Stone Age, of which so many proofs have recently been collected. Where shall we be in our turn when, after another period of equal duration, the pole will have again returned to its present position? French, English, Germans, Italians, Spaniards, may then join hands in a common obscurity. None of our contemporary nations will have resisted the transforming work of time. Other nations, other languages, other religions will have long since replaced the present state of things. One day a traveler wandering on the banks of the Seine will be attracted by a heap of ruins, seeking the place where Paris had, during so many ages, shed its light. Perhaps he will find the same difficulty in recovering places formerly famous that the antiquary now finds in identifying the site of Thebes or of Babylon. Our nineteenth century will be then, in antiquity, very much further back than are for us the ages of the Pharaohs and the ancient Egyptian dynasties. A new human race intellectually superior to ours will have won its way to the sunlight; and we shall perhaps be very surprised, you and I, O studious and thoughtful readers! to meet each other, side by side—blanched and carefully labeled skeletons—installed in a glass case of a museum, by a naturalist of the two hundred and seventy-sixth century, as curious specimens of an ancient race, rather wild, but already endowed with a certain aptitude for the study of the sciences. Vanity of vanities! O noisy ambitions of a day, who pass our life disputing about tinsel, about empty titles and many-colored decorations, ask yourselves what philosophy must think of your ephemeral vainglory when it compares your puerile rivalries with the majestic work of Nature, which bears us all to the same destiny!—FLAMMARION *Popular Astronomy*, bk. i, ch. 4, p. 41. (A.)

2703. PRECIOUS DESTROYED BY WORTHLESS—*Weeds Kill Pasturage.*—The most noxious weed in New Zealand appears, . . . to be the *Hypochœris radicata*, a coarse, yellow-flowered composite not uncommon in our meadows and waste places. This has been introduced with grass seeds from England, and is very destructive. It is stated that excellent pasture was in three years destroyed by this weed, which absolutely displaced every other plant on the ground.—WALLACE *Darwinism*, ch. 2, p. 20. (Hum., 1889.)

2704. PRECIOUSNESS OF LOWLY LIFE—*Biology Values the Humblest.*—It is a well-established fact in biology that the humblest creature is just as important a link in the chain of creation as the highest mammal. The higher forms are so well known, and so little has been found out concerning some of the more lowly creatures, that the naturalist is very glad to leave the ninety-and-nine and go into the wilderness to seek the one that is lost.—MASON *Origins of Invention*, ch. 12, p. 413. (S., 1899.)

2705. PRECIPITATION OF MINERALS KEEPS WATER PURE—*Rocks Now Forming in the Rhone, the Adriatic, and the Mediterranean.*—The Rhone, the Po, the Nile, and many hundred minor streams and springs pour annually into the Mediterranean large quantities of carbonate of lime, together with iron, magnesia, silica, alumina, sulfur, and other mineral ingredients in a state of chemical solution. To explain why the influx of this matter does not alter the composition of this sea has never been regarded as a difficulty; for it is known that calcareous rocks are forming in the delta of the Rhone, in the Adriatic, on the coast of Asia Minor, and in other localities. Precipitation is acknowledged to be the means whereby the surplus mineral matter is disposed of, after the consumption of a certain portion in the secretions of testacea, zoophytes, and other marine animals.—LYELL *Principles of Geology*, bk. ii, ch. 20, p. 335. (A., 1854.)

2706. PRECISION OF SCIENCE—*Minute Exactness of Measurement Led to Discovery of Velocity of Light—The Satellites of Jupiter.*—Römer watched this moon [of Jupiter], saw it move round in front of the planet, pass to the other side of it, and then plunge into Jupiter's shadow, behaving like a lamp suddenly extinguished; at the second edge of the shadow he saw it reappear, like a lamp suddenly lighted. The moon thus acted the part of a signal-light to the astronomer, and enabled him to tell exactly its time of revolution. The period between two successive lightings-up of the lunar lamp he found to be 42 hours, 28 minutes, and 35 seconds. This measurement of time was so accurate that, having determined the moment when the moon emerged from the shadow, the moment of its hundredth appearance could also be determined. In fact, it would be 100 times 42 hours, 28 minutes, 35 seconds after the first observation. Römer's first observation was made when the earth was in the part of its orbit nearest Jupiter. About six months afterwards, the earth being then at the opposite side of its orbit, when the little moon ought to have made its hundredth appearance, it was found unpunctual, being fully 15 minutes behind its calculated time. Its appearance, moreover, had been growing gradually later as the earth retreated towards the part of its orbit most distant from Jupiter. Römer reasoned thus: "Had I been able to remain at the other side of the earth's orbit the moon might have appeared always at the proper instant; an observer placed there would probably have seen the moon 15 minutes ago, the retardation in my case being due to the fact that the light requires 15 minutes to travel from the place where my first observation was made to my present position."

This flash of genius was immediately succeeded by another. "If this surmise be correct," Römer reasoned, "then as I approach Jupiter along the other side of the earth's orbit the retardation ought to become gradually less, and when I reach the place of my first observation there ought to be no retardation at all." He found this to be the case, and thus not only proved that light required time to pass through space, but also determined its rate of propagation. —TYNDALL *Lectures on Light*, lect. 1, p. 20. (A., 1898.)

2707. ——— ——— *Observation Needs Correction by Deeper Knowledge—The Apparent Not the Real.*—Direct observation furnishes only what has been called the "raw material" of the positions of the heavenly bodies. A number of highly complex corrections have to be applied before their mean can be disengaged from their apparent places on the sphere. Of these, the most considerable and familiar is atmospheric refraction, by which objects seem to stand higher in the sky than they in reality do, the effect being evanescent at the zenith, and attaining, by gradations varying with conditions of pressure and temperature, a maximum at the horizon. Moreover, the points to which measurements are referred are themselves in motion, either continually in one direction, or periodically to and fro. The precession of the equinoxes is slowly progressive, or rather retrogressive; the nutation of the pole oscillatory in a period of about eighteen years—added to which, the non-instantaneous transmission of light, combined with the movement of the earth in its orbit, causes a minute displacement known as aberration. Now it is easy to see that any uncertainty in the application of these corrections saps the very foundations of exact astronomy.—CLERKE *History of Astronomy*, pt. i, ch. 2, p. 37. (Bl., 1893.)

2708. ——— ——— *Telegraphic Notation of Time—Buoy of Sunken Cable Found on the High Sea.*—To show what could be done if there were perfect means of determining the time, the following narrative may be cited: When the "Great Eastern" is carrying a telegraph cable across the Atlantic, her captain, of course, knows the true Greenwich time within a single second, for it is flashed to him from Valentia. He can therefore determine his true place with great accuracy. Now it chanced that on one occasion the captain of the "Great Eastern," while thus in telegraphic communication with Greenwich through Valentia, had occasion to search for a buoy which had been left floating (attached to a sunk cable) in a particular latitude and longitude. He made for the spot according to his calculated latitude and longitude, and (according to the account) after the final directions had been given to the effect that the ship should follow a certain course for a certain time he went below to examine a chart. When the time came he was about to go on deck, hoping to have made his course so truly that the buoy would be in sight; but at that very instant the ship's side was struck by the buoy.—PROCTOR *Expanse of Heaven*, p. 34. (L. G. & Co., 1897.)

2709. ——— ——— *Volcanic Dust of Iceland, Fallen in Norway, Identified in Germany.*—We sometimes meet with this far-traveled, volcanic dust under very unexpected circumstances. Thus, in the spring of 1875 I had occasion to visit Professor Vom Rath, of Bonn, who showed me a quantity of fine volcanic dust which had during the past winter fallen in considerable quantities in certain parts of Norway. This dust, upon microscopic examination, proved to be so similar to what was known to be frequently ejected from the Icelandic volcanoes that a strong presumption was raised that volcanic outbursts had been going on in that island. On returning to England I found that the first steamer of the season had just reached Leith from Iceland, bringing the intelligence that very violent erup-

tions had taken place during the preceding months.—JUDD *Volcanoes*, ch. 4, p. 72. (A., 1899.)

2710. PREDICTION OF CONDUCT— *Perfect Knowledge Would Be Perfect Foreknowledge.*—We can predict conduct with almost perfect certainty when we know character with an equal measure of assurance, and when we know the influences to which that character will be exposed. In proportion as we are sure of character, in the same proportion we are sure of conduct. Yet we never think of the will being the less free because we can predict its course. What we know in such cases is simply the use which, under given conditions, will be made of freedom. There is no certainty in the world of physics more absolute than some certainties in the world of mind. We know that a humane man will not do a uselessly cruel action. We know that an honorable man will not do a base action. And if in such cases we are deceived in the result, we know that it is because we were ignorant of some weakness or of some corruption; that is to say, we were ignorant of some elements of character. But we never doubt that if those had been known we could have foreseen the resulting lapse. Perfect knowledge must therefore be perfect foreknowledge. To know the present perfectly is to know the future certainly. To know all that is, is to know all that will be. To know the heart of man completely is to know his conduct completely also; for "out of the heart are the issues of life." So far from this conclusion being dangerous or hostile to any part of the Christian system, it is a conclusion which enables us, in a dim way, not merely to hold as a belief, but to see as a necessary truth that there can be no chance in this world—and how it is, and must be, that to the All-seeing and All-knowing the future is as open as the present and the past. But none of these ideas involve the idea of compulsion, and the absence of compulsion is all that can be meant by freedom.—ARGYLL *Reign of Law*, ch. 6, p. 185. (Burt.)

2711. PREDICTION OF EARTHQUAKES—*True Prophecies Remembered, Erroneous Forgotten.*—Certain persons with whom I am intimate appear to have persuaded themselves that they can foretell the coming of an earthquake by the sultry state of the atmosphere or a certain oppressiveness they feel, and an instinctive feeling arises that an earthquake is at hand. . . . The author has had such sensations himelf, due, perhaps, to a knowledge that it was the earthquake season, that there had been no disturbance for some weeks, and a consequent increasing state of nervous presentiment. In consequence of this not only has he carefully prepared his instruments for the coming shock, but he has written and telegraphed to friends to do the same. Sometimes these guesses have proved correct. One remarkable instance was a few hours prior to the severe shock of February 22, 1880, when he wired to his friends in Yokohama and asked them to see that their instruments were in good order. Oftener, however, his prognostications have been incorrect. The point in connection with this subject which he wishes to be remarked is, that the instances where earthquakes occurred shortly after the receipt of his letters are carefully remembered, and often mentioned, but the instances in which earthquakes did not occur appear to be entirely forgotten. He is led to mention these facts because they appear to be an experimental proof of what has taken place in bygone times, and what still takes place, especially amongst savages—namely, that the record of that which is remarkable survives, whilst that which is of every-day occurrence quickly dies.—MILNE *Earthquakes*, ch. 18, p. 302. (A., 1899.)

2712. PREDICTION, SCIENTIFIC, FULFILLED—*Pasteur and Silkworms.*—It was not . . . easy to make the [silkworm] cultivators accept new guidance. To strike their imagination, and if possible determine their practise, Pasteur hit upon the expedient of prophecy. In 1866 he inspected, at St. Hippolyte-du-Fort, fourteen different parcels of eggs intended for incubation. Having examined a sufficient number of the moths which produced these eggs, he wrote out the prediction of what would occur in 1867, and placed the prophecy as a sealed letter in the hands of the Mayor of St. Hippolyte. In 1867 the cultivators communicated to the mayor their results. The letter of Pasteur was then opened and read, and it was found that in twelve out of fourteen cases there was absolute conformity between his prediction and the observed facts. Many of the groups had perished totally: the others had perished almost totally; and this was the prediction of Pasteur. In two out of the fourteen cases, instead of the prophesied destruction, half an average crop was obtained.—TYNDALL *Floating Matter of the Air*, essay 1, p. 13. (A., 1895.)

2713. ——— ——— *Scientist Foretells Result of Ignoring Scientific Laws—Lighting-mast on Capitol Destroyed by Electricity.*—[An] apparatus had been erected at great expense for the purpose of lighting the public grounds. It consisted of a mast reaching to the height of ninety feet above the apex of the dome of the Capitol [at Washington], terminated by a lantern about five feet in diameter and six or seven feet high. In this were jet gas-burners, equal in illuminating power, according to the statement of the projector of the arrangement, to six thousand wax candles.

After the whole apparatus had been prepared, the speaker was requested to give an opinion as to the effect which the lightning might have upon it. His answer was that it would attract the lightning from the

heavens, and tho the building might be protected by good conductors from the lantern to the earth, yet no protection which the present state of science could devise would be as safe as no exposure; the very idea of protection involving that of a less degree of danger. Tho in the case of the ordinary lightning-rod the lightning is seldom or never attracted from the cloud by the conductor, yet in this case the great height of the mast, the height of the dome above the ground, and the elevated position of the building itself gave a total elevation bearing a considerable ratio to the height of the cloud; add to this the great amount of metallic surface, and, above all, the large gas-burner, and we have an arrangement well calculated to elicit a discharge from the cloud when under ordinary influences no effect of the kind would take place. . . . The fixture on the Capitol was indeed an exploring apparatus on a magnificent scale. The result was such as had been anticipated. The first thunder-storm which passed over the city after the erection of the lantern discharged itself upon it, put out the light, and when the whole was taken down several perforations were found melted in the copper ball which surmounted the lantern. —HENRY *Remarks on the Form of Lightning-Rods (Scientific Writings*, vol. i, p. 291). (Sm. Inst., 1886.)

2714. PREOCCUPATION OF MIND PRODUCES INSENSIBILITY TO PAIN—The writer has himself frequently begun a lecture whilst suffering neuralgic pain so severe as to make him apprehend that he would find it impossible to proceed; yet no sooner has he by a determined effort fairly launched himself into the stream of thought than he has found himself continuously borne along without the least distraction until the end has come and the attention has been released, when the pain has recurred with a force that has overmastered all resistance, making him wonder how he could have ever ceased to feel it.—CARPENTER *Mental Physiology*, ch. 3, p. 138. (A., 1900.)

2715. PREPARATION, NATURE'S, FOR MOTHERHOOD—*Four Great Steps—The Young Fewer in Number, Recognizable at Birth, Needing Mother's Care, and Necessary to Mother's Comfort.*—Now, before maternal love can be evolved out of this first care, before love can be made a necessity, and carried past the unhatched egg to the living thing which is to come out of it, Nature must alter all her ways. Four great changes at least must be introduced into her program. In the first place she must cause fewer young to be produced at a birth. In the second place she must have these young produced in such outward form that their mothers will recognize them. In the third place, instead of producing them in such physical perfection that they are able to go out into life the moment they are born, she must make them helpless, so that for a time they must dwell with her if they are to live at all. And fourthly, it is required that she shall be made to dwell with them; that in some way they also should be made necessary—physically necessary—to her to compel her to attend to them. All these beautiful arrangements we find carried out to the last detail. A mother is made, as it were, in four processes. She requires, like the making of a colored picture, four separate paintings, each adding some new thing to the effect.—DRUMMOND *Ascent of Man*, ch. 8, p. 272. (J. P., 1900.)

2716. PRESENCE THAT FILLS IMMENSITY, THE—*Exalted Conception of the Divine Majesty.*—Shall we say, then, of these vast luminaries that they were created in vain? Were they called into existence for no other purpose than to throw a tide of useless splendor over the solitudes of immensity? Our sun is only one of these luminaries, and we know that he has worlds in his train. Why should we strip the rest of this princely attendance? Why may not each of them be the center of his own system, and give light to his own worlds? It is true that we see them not; but could the eye of man take its flight into those distant regions it would lose sight of our little world before it reached the outer limits of our system—the greater planets would disappear in their turn—before it had described a small portion of that abyss which separates us from the fixed stars, the sun would decline into a little spot, and all its splendid retinue of worlds be lost in the obscurity of distance; he would at last shrink into a small, indivisible atom, and all that could be seen of this magnificent system would be reduced to the glimmering of a little star. Why resist any longer the grand and interesting conclusion? Each of these stars may be the token of a system as vast and as splendid as the one which we inhabit. Worlds roll in these distant regions, and these worlds must be the mansions of life and of intelligence. In yon gilded canopy of heaven we see the broad aspect of the universe, where each shining point presents us with a sun, and each sun with a system of worlds; where the Divinity reigns in all the grandeur of his attributes; where he peoples immensity with his wonders, and travels in the greatness of his strength through the dominions of one vast and unlimited monarchy.—CHALMERS *Astronomical Discourses*, p. 31. (R. Ct., 1848.)

2717. PRESENT, THE ETERNAL—*A Spirit Projected Timelessly through Space Would See Ancient Deeds and Scenes as Present Fact—The Omnipresent also the Omniscient—"The High and Lofty One That Inhabiteth Eternity" (Is. lvii, 15).*—A man, a spirit, leaving the earth, either by death or otherwise, this year, and transported in some hours or days to a great distance, would see the earth of former times, and

would see himself again a child, for the aspect of the earth would not arrive where he was till after a long delay.

There is here neither a vision, nor a phenomenon of memory, nor a marvelous or supernatural action, but an actual, positive, natural, and incontestable fact; what has been for a long time the past for the earth is only the present for a distant observer in space. This vision is, none the less, very astonishing. Indeed, it is a singular fact that it is impossible to see the stars as they are at the moment when we examine them, and that we are only able to see their past!

Thus the progressive motion of light carries with it through infinitude the ancient history of all the suns and all the worlds expressed in an eternal present.

The metaphysical reality of this vast problem is such that we can now conceive the omnipresence of the world in all its duration. Events vanish for the place which brings them forth, but they remain in space. This successive and endless projection of all the facts accomplished on each of the worlds is performed in the bosom of the Infinite Being whose omnipresence thus maintains everything in an eternal permanence.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 7, p. 617. (A.)

2718. PRESENT THE KEY TO PAST—*Rocks Worn Down Now as in Ancient Days.*—The present, geologists tell us, contains the key to the past. If we wish to find out how rocks have been removed, and what has since become of them, we must observe what is taking place under the influence of existing agents of change. How, then, are rocks being affected at present? We do not proceed far in our investigation before we discover that they are everywhere becoming disintegrated. In one place they are breaking up into angular fragments; in another, crumbling down into grit, sand, or clay. Brooks and rivers and the waves upon our coasts are constantly undermining them; everywhere, in short, rocks are being assaulted and reduced.—GEIKIE *Earth Sculpture*, ch. 2, p. 18. (G. P. P., 1898.)

2719. PRESERVATION OF STATUES IN BED OF LAVA—*Long-enduring Heat.*—But it must not be supposed that this complete fusion of rocky matter coming in contact with lava is of universal or even common occurrence. It probably happens when fresh portions of incandescent matter come successively in contact with fusible materials. In many of the dikes which intersect the tuffs and lavas of Etna there is scarcely any perceptible alteration effected by heat on the edges of the horizontal beds, in contact with the vertical and more crystalline mass. On the side of Mompiliere, one of the towns overflowed in [a previous] eruption . . . , an excavation was made in 1704, and by immense labor the workmen reached, at the depth of thirty-five feet, the gate of the principal church, where were three statues, held in high veneration. One of these, together with a bell, some money, and other articles, was extracted in a good state of preservation from beneath a great arch formed by the lava. It seems very extraordinary that any works of art, not encased with tuff, like those in Herculaneum, should have escaped fusion in hollow spaces left open in this lava-current, which was so hot at Catania eight years after it entered the town that it was impossible to hold the hand in some of the crevices.—LYELL *Principles of Geology*, bk. ii, ch. 25, p. 401. (A., 1854.)

2720. PRESSURE IN DEPTHS OF OCEAN—At a depth of 2,500 fathoms the pressure is, roughly speaking, two and a half tons per square inch—that is to say, several times greater than the pressure exerted by the steam upon the piston of our most powerful engines. Or, to put the matter in other words, the pressure per square inch upon the body of every animal that lives at the bottom of the Atlantic Ocean is about twenty-five times greater than the pressure that will drive a railway train.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 19. (A., 1894.)

2721. ——— *Drives Water into Pores of Sunken Wood.*—If wood be sunk to vast depths in the sea it may be impregnated with water suddenly. Captain Scoresby informs us, in his "Account of the Arctic Regions," that on one occasion a whale, on being harpooned, ran out all the lines in the boat, which it then dragged under water, to the depth of several thousand feet, the men having just time to escape to a piece of ice. When the fish returned to the surface "to blow" it was struck a second time, and soon afterwards killed. The moment it expired it began to sink—an unusual circumstance, which was found to be caused by the weight of the sunken boat, which still remained attached to it. By means of harpoons and ropes the fish was prevented from sinking until it was released from the weight by connecting a rope to the lines of the attached boat, which was no sooner done than the fish rose again to the surface. The sunken boat was then hauled up with great labor, for so heavy was it that, altho before the accident it would have been buoyant when full of water, yet it now required a boat at each end to keep it from sinking. "When it was hoisted into the ship the paint came off the wood in large sheets, and the planks, which were of wainscot, were as completely soaked in every pore as if they had lain at the bottom of the sea since the flood! A wooden apparatus that accompanied the boat in its progress through the deep, consisting chiefly of a piece of thick deal about fifteen inches square, happened to fall overboard, and tho it originally consisted of the lightest fir, sank in the water like a stone. The boat was rendered useless; even the wood of which it was

built, on being offered to the cook for fuel, was tried and rejected as incombustible."—LYELL *Principles of Geology*, bk. iii, ch. 47, p. 743. (A., 1854.)

2722. ——— ——— *Glass Crushed to Powder—Implosion vs. Explosion.*—A most beautiful experiment to illustrate the enormous force of this pressure was made during the voyage of H. M. S. "Challenger." I give the description of it in the words of the late Professor Moseley:

"Mr. Buchanan hermetically sealed up at both ends a thick glass tube full of air, several inches in length. He wrapped this sealed tube in flannel and placed it, so wrapped up, in a wide copper tube, which was one of those used to protect the deep-sea thermometers when sent down with the sounding apparatus.

"This copper tube was closed by a lid fitting loosely, and with holes in it, and the copper bottom of the tube similarly had holes bored through it. The water thus had free access to the interior of the tube when it was lowered into the sea, and the tube was necessarily constructed with that object in view, in order that in its ordinary use the water should freely reach the contained thermometer.

"The copper case containing the sealed glass tube was sent down to a depth of 2,000 fathoms and drawn up again. It was then found that the copper wall of the case was bulged and bent inwards opposite the place where the glass tube lay, just as if it had been crumpled inward by being violently squeezed.

"The glass tube itself, within its flannel wrapper, was found when withdrawn reduced to a fine powder, like snow almost. What had happened was that the sealed glass tube, when sinking to gradually increasing depths, had held out long against the pressure, but this at last had become too great for the glass to sustain, and the tube had suddenly given way and been crushed by the violence of the action to a fine powder. So violent and rapid had been the collapse that the water had not had time to rush in by means of the holes at both ends of the copper cylinder, and thus fill the empty space left behind by the collapse of the glass tube, but had instead crushed in the copper wall and brought equilibrium in that manner. The process is exactly the reverse of an explosion, and is termed by Sir Wyville Thomson an 'implosion.'"—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 19. (A., 1894.)

2723. PRESSURE OF GLACIER—*Giant Power of Natural Agencies.*—The glacier does more than abrade. Rocks are not homogeneous; they are intersected by joints and places of weakness, which divide them into virtually detached masses. A glacier is undoubtedly competent to root such masses bodily away. Indeed, the mere a priori consideration of the subject proves the competence of a glacier to deepen its bed. Taking the case of a glacier 1,000 feet deep (and some of the older ones were probably three times this depth), and allowing 40 feet of ice to an atmosphere, we find that on every square inch of its bed such a glacier presses with a weight of 375 lbs., and on every square yard of its bed with a weight of 486,000 lbs. With a vertical pressure of this amount the glacier is urged down its valley by the pressure from behind. We can hardly, I think, deny to such a tool a power of excavation.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 239. (A., 1898.)

2724. ——— ——— *Its Grinding Power.*—The movement of glacial ice causes friction and leads to the grinding, smoothing, and scratching of the rocks over which it passes. The intensity of this grinding can be appreciated to some extent by considering the force with which a thick ice mass presses on the rocks beneath. The weight of a cubic foot of ice is about fifty-seven pounds, hence a glacier 1,000 feet thick, which is by no means the maximum, would exert a pressure on its bed of twenty-eight tons to the square foot. A movement of ice charged with sand and stones under such a pressure cannot fail to produce abrasion of the rocks beneath.—RUSSELL *Glaciers of North America*, int., p. 18. (G. & Co., 1897.)

2725. PREVISION IN BIRDS AND INSECTS—*Mystery of Lower Organisms.*—Those birds and insects whose young are hatched by the heat of fermentation have an intuitive impulse to select the proper materials, and to gather them for the purpose. All creatures, guided sometimes apparently by senses of which we know nothing, are under like impulses to provide effectually for the nourishing of their young. It is, moreover, most curious and instructive to observe that the extent of prevision which is involved in this process and in the securing of the result seems very often to be greater as we descend in the scale of Nature, and in proportion as the parents are dissociated from the actual feeding or personal care of their young. The mammalia have nothing to provide except food for themselves, and have at first, and for a long time, no duty to perform beyond the discharge of a purely physical function. Milk is secreted in them by a purely unconscious process, and the young need no instruction in the art of sucking. Birds have much more to do—in the building of nests, in the choice of sites for these, and, after incubation, in the choice of food adapted to the period of growth. Insects, much lower in the scale of organization, have to provide very often for a much more distant future, and for various stages of development.—ARGYLL *Unity of Nature*, ch. 2, p. 40. (Burt.)

2726. PREVISION IN INSECTS—*Ants Caring for Eggs of Aphides.*—Here are aphides, not living in the ants' nests, but out-

side, on the leaf-stalks of plants. The eggs are laid early in October on the food-plant of the insect. They are of no direct use to the ants, yet they are not left where they are laid, exposed to the severity of the weather and to innumerable dangers, but brought into their nests by the ants, and tended by them with the utmost care through the long winter months until the following March, when the young ones are brought out and again placed on the young shoots of the daisy. This seems to me a most remarkable case of prudence. Our ants may not, perhaps, lay up food for the winter, but they do more, for they keep during six months the eggs which will enable them to procure food during the following summer, a case of prudence unexampled in the animal kingdom.—AVEBURY *Ants, Bees, and Wasps,* ch. 4, p. 73. (A., 1900.)

2727. ——— ——— *The Carpenter-bee —Remarkable Congenital Instinct of Larvæ.*—The carpenter-bee was first observed and described by Réaumur. It makes a long cylindrical tube in the wood of beams, palings, etc. This it divides into a number of successive chambers by partitions made of agglutinated sawdust built across the tube at right angles to its axis. In each chamber there is deposited a single egg, together with a store of pollen for the nourishment of the future larva. The larvæ hatch out in succession and in the order of their age—*i. e.*, the dates at which they were deposited. To provide for this, the bee bores a hole from the lower cell to the exterior, so that each larva, when ready to escape from its chamber, finds an open way from the tube. The larvæ have to cut their own way out through the walls of their respective chambers, and it is remarkable that they always cut through the wall that faces the tubular passage left by the parent; they never bore their way out in the opposite direction, which, were they to do so, would entail the destruction of all the other and immature larvæ.—ROMANES *Animal Intelligence,* ch. 4, p. 179. (A., 1899.)

2728. PREVISION OF THOUGHT—*Emphasis in Reading Shows Sense of Words to Come.*—How comes it about that a man reading something aloud for the first time is able immediately to emphasize all his words aright, unless from the very first he have a sense of at least the form of the sentence yet to come, which sense is fused with his consciousness of the present word, and modifies its emphasis in his mind so as to make him give it the proper accent as he utters it? Emphasis of this kind is almost altogether a matter of grammatical construction. If we read "no more" we expect presently to come upon a "than"; if we read "however" at the outset of a sentence it is a "yet," a "still," or a "nevertheless" that we expect. A noun in a certain position demands a verb in a certain mood and number, in another position it expects a relative pronoun. Adjectives call for nouns, verbs for adverbs, etc., etc. And this foreboding of the coming grammatical scheme combined with each successive uttered word is so practically accurate that a reader incapable of understanding four ideas of the book he is reading aloud can nevertheless read it with the most delicately modulated expression of intelligence.—JAMES *Psychology,* vol. i, ch. 9, p. 253. (H. H. & Co., 1899.)

2729. PRIDE OF HALF-KNOWLEDGE —*Scientific Basis for Practical Precaution— Thin Coverings Protect from Frost.*—We have the following beautiful passage in the "Essay" of Wells: "I had often, in the pride of half-knowledge, smiled at the means frequently employed by gardeners to protect tender plants from cold, as it appeared to me impossible that a thin mat or any such flimsy substance could prevent them from attaining the temperature of the atmosphere, by which alone I thought them liable to be injured. But when I had learned that bodies on the surface of the earth become, during a still and serene night, colder than the atmosphere, by radiating their heat to the heavens, I perceived immediately a just reason for the practise which I had before deemed useless."—TYNDALL *Heat a Mode of Motion,* lect. 17, p. 500. (A., 1900.)

2730. PRINCIPLE OF LIFE ONE THROUGH ALL NATURE AND ALL TIME —Whatever else may be true, the conviction is brought home to us that in all this endless multifariousness there is one single principle at work, that all is tending toward an end that was involved from the very beginning, if one can speak of beginnings and ends where the process is eternal. The whole universe is animated by a single principle of life; and whatever we see in it, whether to our half-trained understanding and narrow experience it may seem to be good or bad, is an indispensable part of the stupendous scheme.—FISKE *Through Nature to God,* pt. i, ch. 4, p. 24. (H. M. & Co., 1900.)

2731. PRINCIPLES, NEW, OF LOCOMOTION—*Changes in Habits and Speech.*— During the nineteenth century three distinct modes of locomotion have been originated and brought to a high degree of perfection. Two of them, the locomotive and the steamship, are altogether different in principle from what had gone before. Up to the very times of men now living, all our locomotion was on the same old lines which had been used for thousands of years. It had been improved in details, but without any alteration of principle and without any very great increase of efficiency. The principles on which our present methods rest are new; they already far surpass anything that could be effected by the older methods; with wonderful rapidity they have spread

over the whole world, and they have in many ways modified the habits and even the modes of speech of all civilized peoples.—WALLACE *The Wonderful Century*, ch. 1, p. 10. (D. M. & Co., 1899.)

2732. PRINTING INVENTED IN CHINA—*Block-books.*—This [printing] was a process simple enough in itself, and indeed well known from remote ages. Every Egyptian or Babylonian who smeared some black on his signet-ring or engraved cylinder, and took off a copy, had made the first step towards printing. But easy as the further application now seems to us, no one in the Old World saw it. It appears to have been the Chinese who invented the plan of engraving a whole page of characters on a wood-block and printing off many copies. They may have begun as early as the sixth century, and at any rate in the tenth century they were busy printing books. The Chinese writing, from its enormous diversity of characters, is not well suited to printing by movable types, but there is a record that this plan was early devised among them, having been carried on with separate terra-cotta types in the eleventh century. Moslem writers early in the fourteenth century describe Chinese printing, so that it was probably through them that the art found its way to Europe, where not long afterwards the so-called "block-books," printed from whole-page wood-blocks after the Chinese manner, make their appearance, followed by books printed with movable types. Few questions have been more debated by antiquaries than the claims of Gutenberg, Faust, and the others to their share of honor as the inventors of printing. Great as was the service these worthies did to the world, it is only fair to remember that what they did was but to improve the practical application of a Chinese invention. Since their time progress has been made in cheapening types, making paper by machinery, improving the presses, and working them by steam-power, but the idea remains the same.—TYLOR *Anthropology*, ch. 7, p. 180. (A., 1899.)

2733. PRIORITY OF DISCOVERY, SPURIOUS CLAIMS OF—*Everything Said by Some One Somewhere—Chance Utterance Is Not Discovery.*—In the hundreds of books and pamphlets which are every year published about ether, the structure of atoms, the theory of perception, as well as on the nature of the asthenic fever and carcinoma, all the most refined shades of possible hypotheses are exhausted, and among these there must necessarily be many fragments of the correct theory. But who knows how to find them? I insist upon this in order to make clear to you that all this literature, of untried and unconfirmed hypotheses, has no value in the progress of science. One who wants to publish something really new—facts—sees himself open to the danger of countless claims of priority, unless he is prepared to waste time and power in reading beforehand a quantity of absolutely useless books, and to destroy his readers' patience by a multitude of useless quotations.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 229. (L. G. & Co., 1898.)

2734. ——— ——— *Truth May Appear by Accident amid Any Flood of Error—Discovery Gives Reason and Proof of Truth.*—To find superficial resemblances is easy; it is amusing in society, and witty thoughts soon procure for their author the name of a clever man. Among the great number of such ideas there must be some which are ultimately found to be partially or wholly correct; it would be a stroke of skill always to guess falsely. In such a happy chance a man can loudly claim his priority for the discovery; if otherwise, a lucky oblivion conceals the false conclusions. The adherents of such a process are glad to certify the value of a first thought. Conscientious workers who are shy at bringing their thoughts before the public before they have tested them in all directions, solved all doubts, and have firmly established the proof, these are at a decided disadvantage.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 228. (L. G. & Co., 1898.)

2735. PROBLEM OF LAW AND LIBERTY—*How Much Control by Government?—How Much Freedom, Even if Abused?*—As the motives which determine individual conduct are not always reasonable motives, so it is clear that what men naturally do is no sure test either of what they ought to do or of what they ought to be allowed to do. It is their nature, under certain conditions, to do all that is bad and injurious to themselves and others. Hence it is the most difficult of all problems in the science of government to determine when, where, and how it is wise to interfere by the authority of law with the motives which are usually called the natural motives of men. The question is no other than this: How far the abuse of those motives can be checked and resisted by that public authority whose duty and function it is to place itself above the influences which, in individual men, overpower the voice of reason and of conscience.—ARGYLL *Reign of Law*, ch. 7, p. 199. (Burt.)

2736. PROBLEM OF MORAL EVIL—*Why Is Righteousness Not Automatic?*—The question then arises, as one of the greatest of all mysteries, how it is and why it is that the higher gifts of man's nature should not have been associated with corresponding dispositions to lead as straight and as unerringly to the crown and consummation of his course as the dispositions of other creatures do lead them to the perfect development of their powers and the perfect discharge of their functions in the economy of Nature?—ARGYLL *Unity of Nature*, ch. 9, p. 219. (Burt.)

2737. PROBLEM OF SCIENCE, A— *Flowers and Trees Absorb Different Colors —Is the Plant Affected by the Difference?*— Both in foliage and in flowers we have striking differences of absorption. The copper beech and the green beech, for example, take in different rays. But the very growth of the tree is due to some of the rays thus taken in. Are the chemical rays, then, the same in the copper and the green beech? In two such flowers as the primrose and the violet, where the absorptions, to judge by the colors, are almost complementary, are the chemically active rays the same? The general relation of color to chemical action is worthy of the application of the method by which Dr. Draper proved so conclusively the chemical potency of the yellow rays.—TYNDALL *Lectures on Light,* lect. 1, p. 39. (A., 1898.)

2738. PROBLEM OR HYPOTHESIS NOT TO BE MADE DOCTRINE—" We must draw [it is said] a strict distinction between what we wish to teach and what we wish to search for. The objects of our research are expressed as problems (or hypotheses). We need not keep them to ourselves; we are ready to communicate them to all the world, and say, 'There is the problem; that is what we strive for.' . . . The investigation of such problems, in which the whole nation may be interested, cannot be restricted to any one. This is freedom of inquiry. But the problem (or hypothesis) is not, without further debate, to be made a doctrine."—TYNDALL *Fragments of Science,* vol. ii, ch. 15, p. 397. (A., 1900.)

2739. PROBLEMS OF THE DEEP— When it was found that animals can and do live even at the greatest depths of the ocean, the interest of naturalists was concentrated on the solution of the following problems. Firstly, do the animals constituting the fauna of the abyss exhibit any striking and constant modification in correlation with the physical conditions of their strange habitat? And, secondly, from what source was the fauna of the abyss derived? Was it derived from the shallow shore waters, or from the surface of the sea? Is it of very ancient origin, or the result of, comparatively speaking, recent immigrations?—HICKSON *Fauna of the Deep Sea,* pref., p. 10. (A., 1898.)

2740. PROBLEMS YET UNSOLVED— *Decision of Science Waits for Facts—Tentative Hypotheses.*—It must be admitted, then, that the questions of the nature of the earth's interior and the cause of the high temperatures which produce volcanic phenomena are still open ones. We have not yet got beyond the stage of endeavoring to account for the facts observed by means of tentative hypotheses. Some of these, as we have seen, agree with the facts, so far as they are at present known, much better than others; but the decision between them, or the rejection of the whole of them in favor of some new hypothesis, must depend on the results of future observation and inquiry.—JUDD *Volcanoes,* ch. 12, p. 352. (A., 1899.)

2741. ——— ——— *Vain Search for Intra-Mercurian Planet—Perturbations of Mercury Still Unexplained.*—Intra-Mercurian planets have . . . been diligently searched for when the opportunity of a total eclipse offered, especially during the long obscuration at Caroline Island. Not only did Professor Holden "sweep" in the solar vicinity, but Palisa and Trouvelot agreed to divide the field of exploration, and thus make sure of whatever planetary prey there might be within reach; yet with only negative results. Belief in the presence of any considerable body or bodies within the orbit of Mercury is, accordingly, now at a low ebb. Yet the existence of the anomaly in the Mercurian movements indicated by Le Verrier has been made only surer by further research. Its elucidation constitutes one of the "pending problems" of astronomy.—CLERKE *History of Astronomy,* pt. ii, ch. 7, p. 308. (Bl., 1893.)

2742. PROCESS OF CRYSTALLIZATION SEEN BY MEANS OF SOLAR MICROSCOPE — Cleansing perfectly a glass plate, the solution of the chlorid [common sal ammoniac, or ammonium, dissolved in water] is poured over the glass, to which, when the plate is set on edge, a thin film of the liquid adheres. Warming the glass slightly, evaporation is promoted, but by evaporation the water only is removed. The plate is then placed in a solar microscope, and an image of the film is thrown upon a white screen. The warmth of the illuminating beam adds itself to that already imparted to the glass plate, so that after a moment or two the dissolved salt can no longer exist in the liquid condition. Molecule then closes with molecule, and you have a most impressive display of crystallizing energy overspreading the whole screen. You may produce something similar if you breathe upon the frost-ferns which overspread your window-panes in winter, and then observe through a pocket-lens the subsequent recongelation of the film. In this case the crystallizing force is hampered by the adhesion of the film to the glass; nevertheless, the play of power is strikingly beautiful.—TYNDALL *Lectures on Light,* lect. 3, p. 103. (A., 1898.)

2743. PROCESS SUCCESSFULLY USED, WHILE REASON UNKNOWN— *Real Cause of Fermentation Discovered by Pasteur.*—It was Pasteur who in 1857 first propounded the true cause and process of fermentation. The breaking-down of sugar into alcohol and carbonic acid gas had been known, of course, for a long period. Since the time of Spallanzani (1776) the putrefactive changes in liquids and organic matter had been prevented by boiling and subsequently sealing the flask or vessel con-

taining the fluid. Moreover, this successful preventive practise had been in some measure correctly interpreted as due to the exclusion of the atmosphere, but wrongly credited to the exclusion of the oxygen of the air. It was not until the beginning of the present century that authorities modified their view and declared in favor of yeast-cells as the agents in the production of fermentation.—NEWMAN *Bacteria*, ch. 4, p. 111. (G. P. P., 1899.)

2744. PRODUCT OF EVOLUTION MORE IMPORTANT THAN THE PROCESS —*Love the Final and Supreme Result.*—But, after all, the miracle of evolution is not the process, but the product. Beside the wonder of the result, the problem of the process is a mere curiosity of science. For what is the product? It is not mountain and valley, sky and sea, flower and star, this glorious and beautiful world in which man's body finds its home. It is not the godlike gift of mind nor the ordered cosmos where it finds so noble an exercise for its illimitable powers. It is that which of all other things in the universe commends itself, with increasing sureness as time goes on, to the reason and to the heart of humanity—love. Love is the final result of evolution. This is what stands out in Nature as the supreme creation.—DRUMMOND *Ascent of Man*, ch. 10, p. 335. (J. P., 1900.)

2745. PRODUCT OF SLIGHT FORCE BY VAST PERIOD—*Power of "Patient Continuance" (Rom. ii, 7)—The Silent Activities.*—There is no fact which the geological student is more constantly called upon to bear in mind than that of the potency of seemingly insignificant causes which continue in constant operation through long periods of time. Indeed, these small and almost unnoticed agencies at work upon the earth's crust are often found, in the long run, to produce far grander effects than those of which the action is much more striking and obvious. It is to the silent and imperceptible action of atmospheric moisture and frost that the disintegration of the solid rock-masses must be mainly ascribed; and the noisy cataract and ocean billow produce effects which are quite insignificant compared with those which must be ascribed to the slight and almost unnoticed forces. Great masses of limestone are built up of the remains of microscopic organisms, while the larger and higher life forms contribute but little to the great work of rock-building.—JUDD *Volcanoes*, ch. 10, p. 302. (A., 1899.)

2746. PROFICIENCY INCREASED BY REST—We notice after exercising our muscles or our brain in a new way that we can do so no longer at that time; but after a day or two of rest, when we resume the discipline, our increase in skill not seldom surprises us. I have often noticed this in learning a tune; and it has led a German author to say that we learn to swim during the winter and to skate during the summer.—JAMES *Psychology*, vol. i, ch. 4, p. 110. (H. H. & Co., 1899.)

2747. PROGENY OF LOWER ANIMALS MULTITUDINOUS—*Love Then Impossible—No Ethical Result Attained.*—The humbler denizens of the world produce offspring, not by units or tens, but by thousands and millions; and with populations so vast, maternal protection is not required to sustain the existence of the species. It was probably on the whole a better arrangement to produce a million and let them take their chance, than to produce one and take special trouble with it. It was easier, moreover, a thousand times easier, for Nature to make a million young than one mother. But the ethical effect, if one may use such a term here, of this early arrangement was nil. All this saving of motherly trouble meant for a long space in Nature complete absence of maternal training. With children of this sort motherhood had no chance. There was no time to love, no opportunity to love, and no object to love. It was a period of physical installations; and of psychical installations only as establishing the first stages of the maternal instinct—the prenatal care of the egg. This is a necessary beginning, but it is imperfect; it arrests itself at the critical point, where care can react upon the mother.—DRUMMOND *Ascent of Man*, ch. 8, p. 271. (J. P., 1900.)

2748. PROGRESS BY DISREGARD OF PLEASURE AND PAIN—Pleasure and pain are undoubtedly powerful as spur and bridle and bit in the struggle for existence. But whatever biology and certain doctrines of political economy may see fit to hold on this subject, psychology cannot find that the facts testify to this side of life as being by life any means all-powerful. Indeed, *all human life develops largely by relegating the immediate effects of our activity, as respects the quantities of pleasure or pain evoked, more and more into the background.*—LADD *Psychology*, ch. 10, p. 197. (S., 1899.)

2749. PROGRESS BY INTERCOURSE AND INTERCHANGE—*A Prophet without Honor in His Own Country.*—Humanity would probably not have progressed very far from its original state if the separate tribes and peoples had not mutually exchanged their small steps of progress, and constantly enriched their scanty possessions in culture by borrowing from others. Just the rigidness of the people's soul that timidly refuses every venture, everything untried, justifies the assumption that every nation has derived a great percentage of its endowments and opinions at second hand; [and this is further evident from the fact that] naturally the example of an entire neighboring tribe exercises a stronger and more convincing effect than the most living demonstration from a member of one's own society, whose

ideas in the eyes of his comrades "haven't traveled from a distance." The ancient saying, "A prophet is not without honor save in his own country," illumines the situation. This borrowing would be still more frequent if the petty tribal animosities, which among peoples of higher culture take the form of national pride, did not hinder a more energetic leaning toward foreign standards.—SCHURTZ *Urgeschichte der Kultur*, p. 58. (Translated for *Scientific Side-Lights.)*

2750. PROGRESS CHARACTERIZES TRUE SCIENCE—The beauty of all truly scientific work is to get to ever deeper levels.—JAMES *Psychology*, vol. ii, ch. 25, p. 448. (H. H. & Co., 1899.)

2751. PROGRESS FROM IMPLEMENT TO MACHINE—*From Hand-power to Use of Elemental Forces.*—The ingenuity of man has been eminent in the art of destroying his fellow men. In surveying the last group of deadly weapons, from the stone hurled by hand to the rifled cannon, there comes well into view one of the great advances of culture. This is the progress from the simple tool or implement, such as the club or knife, which enables man to strike or cut more effectively than with hands or teeth, to the machine which, when supplied with force, only needs to be set and directed by man to do his work. Man often himself provides the power which the machine distributes more conveniently, as when the potter turns the wheel with his own foot, using his hands to mold the whirling clay. The highest class of machines are those which are driven by the stored-up forces of Nature, like the sawmill, where the running stream does the hard labor, and the sawyer has only to provide the timber and direct the cutting.—TYLOR *Anthropology*, ch. 8, p. 197. (A., 1899.)

2752. PROGRESS, MENTAL, SUPERSEDES PHYSICAL—*Mind Gives Man Dominion.*—No fact in Nature is fraught with deeper meaning than this two-sided fact of the extreme physical similarity and enormous psychical divergence between man and the group of animals to which he traces his pedigree. It shows that when humanity began to be evolved an entirely new chapter in the history of the universe was opened. Henceforth the life of the nascent soul came to be first in importance, and the bodily life became subordinated to it. Henceforth it appeared that, in this direction at least, the process of zoological change had come to an end, and a process of psychological change was to take its place. Henceforth along this supreme line of generation there was to be no further evolution of new species through physical variation, but through the accumulation of psychical variations one particular species was to be indefinitely perfected and raised to a totally different plane from that on which all life had hitherto existed. Henceforth, in short, the dominant aspect of evolution was to be not the genesis of species, but the progress of civilization.—FISKE *Destiny of Man*, ch. 3, p. 29. (H. M. & Co., 1900.)

2753. PROGRESS OF HUMANITY—*Guides for the Study of Types of Ancient Culture Now Existent.*—There are five guides [from helplessness to power] whose services we have to engage on our interesting journey. The first is History, who does not know the way very far back—not over three thousand years—with much certainty. The second is Philosophy, the study of which in our own century has enabled us to find the cradle-land of many peoples. The third is Folk-lore, the survival of belief and custom among the uneducated. The fourth is Archeology, history written in things. The fifth is Ethnology, which informs us that in describing this arc of civilization some races have only marked time, while others have moved with radii of varying lengths. The result of this is that we now have on the earth types of every sort of culture it has ever known.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891; Proceedings of the Congress*, p. 406).

2754. ——— ——— *Improvement by Individual Effort—Civilization a Condition of Unstable Equilibrium—Hopeful Result of Education.*—There have been various centers and periods of civilization. Egypt, Greece, and Rome, tho they have left an impress upon the world which extends even to our time, and modifies all the present, have themselves "moldered down." It appears, therefore, that civilization itself may be considered as a condition of unstable equilibrium, which requires constant effort to be sustained, and a still greater effort to be advanced. It is not, in my view, the manifest destiny of humanity to improve by the operation of an inevitable necessary law of progress; but while I believe that it is the design of Providence that man should be improved, this improvement must be the result of individual effort, or of the combined effort of many individuals, animated by the same feeling, and cooperating for the attainment of the same end. The world is still in a degraded condition; ignorance, want, rapine, murder, superstition, fraud, uncleanliness, inhumanity, and malignity abound. We thank God, however, that he has given us the promise, and in some cases the foretaste, of a happier and holier condition; that he has vouchsafed to us as individuals, each in his own sphere, the privilege, and has enjoined upon us the duty, of becoming his instruments, and thus coworkers in ameliorating the condition of ourselves and our fellow men; and above all, that he has enabled us through education to improve the generations which are to follow us. If we sow judiciously in the present the world will assuredly reap a beneficent har-

vest in the future; and he has not lived in vain who leaves behind him as his successor a child better educated morally, intellectually, and physically than himself.—HENRY *Thoughts on Education (Scientific Writings*, vol. i, p. 327). (Sm. Inst., 1886.)

2755. PROGRESS OF LIFE IN GEOLOGIC TIME—*Prolific Periods and Epochs.*—Just as the growth of trees is promoted or arrested by the vicissitudes of summer and winter, so in the course of the geological history there have been periods of pause and acceleration in the work of advancement. This is in accordance with the general analogy of the operations of Nature, and is in no way at variance with the doctrine of uniformity already referred to. Nor has it anything in common with the unfounded idea, at one time entertained, of successive periods of entire destruction and restoration of life. Prolific periods of this kind appear in the marine invertebrates of the early Cambrian, the plants and fishes of the Devonian, the batrachians of the Carboniferous, the reptiles of the Trias, the broad-leaved trees of the Cretaceous, and the mammals of the early Tertiary. A remarkable contrast is afforded by the later Tertiary and modern time, in which, with the exception of man himself, and perhaps a very few other species, no new forms of life have been introduced, while many old forms have perished.—DAWSON *Facts and Fancies in Modern Science*, lect. 3, p. 124. (A. B. P. S.)

2756. PROGRESS OF SCIENCE—*Advance by Rejection of Ancient Dogmas—Language Still Preserves Old Forms.*—The dogmas of former ages survive now only in the superstitions of the people and the prejudices of the ignorant, or are perpetuated in a few systems, which, conscious of their weakness, shroud themselves in a veil of mystery. We may also trace the same primitive intuitions in languages exuberant in figurative expressions; and a few of the best chosen symbols engendered by the happy inspiration of the earliest ages, having by degrees lost their vagueness through a better mode of interpretation, are still preserved among our scientific terms.—HUMBOLDT *Cosmos*, vol. i, int., p. 24. (H., 1897.)

2757. ——— ——— *A Rhythmic Movement—Retardation the Prelude to Swifter Advance.*—Newton's espousal of the emission theory [of light] is said to have retarded scientific discovery. It might, however, be questioned whether, in the long run, the errors of great men have not really their effect in rendering intellectual progress rhythmical, instead of permitting it to remain uniform, the "retardation" in each case being the prelude to a more impetuous advance. It is confusion and stagnation, rather than error, that we ought to avoid. Thus, tho the undulatory theory was held back for a time, it gathered strength in the interval, and its development within the last half century has been so rapid and triumphant as to leave no rival in the field.—TYNDALL *Lectures on Light*, lect. 2, p. 80. (A., 1898.)

2758. ——— ——— *New Methods of Research.*—Comparing the methods now available for astronomical inquiries with those in use thirty years ago, we are at once struck with the fact that they have multiplied. The telescope has been supplemented by the spectroscope and the photographic camera. Now this really involves a whole world of change. It means that astronomy has left the place where she dwelt apart in rapt union with mathematics, indifferent to all things on earth save only to those mechanical improvements which should aid her to penetrate further into the heavens, and has descended into the forum of human knowledge, at once a suppliant and a patron, alternately invoking help from and promising it to each of the sciences, and patiently waiting upon the advance of all. The science of the heavenly bodies has, in a word, become a branch of terrestrial physics, or rather a higher kind of integration of all their results.—CLERKE *History of Astronomy*, pt. ii, ch. 13, p. 512. (Bl., 1893.)

2759. PROGRESS, SOCIAL—*Intellectual Beliefs Direct—Feelings Impel to Action—Steam and Steersman.*—It was not human emotions and passions which discovered the motion of the earth, or detected the evidence of its antiquity; which exploded scholasticism, and inaugurated the exploration of Nature; which invented printing, paper, and the mariner's compass. Yet the Reformation, the English and French Revolutions, and still greater moral and social changes yet to come, are direct consequences of these and similar discoveries. Even alchemy and astrology were not believed because people thirsted for gold and were anxious to pry into the future, for these desires are as strong now as they were then; but because alchemy and astrology were conceptions natural to a particular stage in the growth of human knowledge, and consequently determined during that stage the particular means whereby the passions which always exist sought their gratification. To say that men's intellectual beliefs do not determine their conduct is like saying that the ship is moved by the steam and not by the steersman. The steam, indeed, is the motive power; the steersman, left to himself, could not advance the vessel a single inch, yet it is the steersman's will and the steersman's knowledge which decide in what direction it shall move and whither it shall go.—MILL *Positive Philosophy of Auguste Comte*, p. 96. (H. H. & Co., 1887.)

2760. PROGRESS, UNCONSCIOUS—*The Greatest Movements Least Perceptible to Those Borne Onward by Them.*—If we ride in a well-appointed carriage with good

springs, upon a railway which is in excellent order, the movement is almost imperceptible to us, and the rate of speed may be increased indefinitely without making itself apparent to our senses. The smallest impediment to the evenness of the movement—such as that produced by a small object placed upon the rails—at once makes itself felt by a violent jar and vibration. How perfectly insensible we may be of the grandest and most rapid movements is taught us by the facts demonstrated by the astronomer. By the earth's daily rotation we are borne along at a rate which in some places amounts to over 1,000 miles an hour, and by its annual revolution we are every hour transported through a distance of 70,000 miles; yet concerning the fact and direction of these movements we are wholly unconscious.—JUDD *Volcanoes*, ch. 10, p. 285. (A., 1899.)

2761. PROOF, FIRST, OF DEEP-SEA FAUNA—*Commercial Industry Aids Science.*—The first direct proof of the existence of an invertebrate fauna in deep seas was found by the expedition that was sent to repair the submarine cable of the Mediterranean Telegraph Company. The cable had broken in deep water, and a ship was sent out to examine and repair the damage. When the broken cable was brought on deck it bore several forms of animal life that must have become attached to it and lived at the bottom of the sea in water extending down to a depth of 1,200 fathoms. Among other forms a caryophyllia was found attached to the cable at 1,100 fathoms, an oyster *(Ostrea cochlear)*, two species of pecten, two gasteropods, and several worms.—HICKSON *Fauna of the Deep Sea*, ch. 1, p. 7. (A., 1894.)

2762. PROOFS FROM THE VAST AND THE MINUTE UNITE—*Gases Imprisoned in the Fluid Rock of Volcanoes.*—That the molten materials which issue from volcanic vents have absorbed enormous quantities of steam and other gases we have the most undisputable evidence. The volume of such gases given off during volcanic outbursts, and while the lava-streams are flowing and consolidating, is enormous, and can only be accounted for by supposing that the masses of fluid rock have absorbed many times their volume of the gases. But we have another not less convincing proof of the same fact in the circumstance that volcanic materials which have consolidated under great pressure—such as granites, gabbros, porphyries, etc.—exhibit in their crystals innumerable cavities containing similar gases in a liquefied state.

It is to the violent escape of these gases from the molten rock-masses, as the pressure upon them is relieved, that nearly all the active phenomena of volcanoes must be referred.—JUDD *Volcanoes*, ch. 12, p. 357. (A., 1899.)

2763. PROPAGATION, RECTILINEAR, OF LIGHT—*Crossing of Rays with Inversion of Image—Overlapping Images.*—The following instructive experiment depends on the rectilinear propagation of light. Make a small hole in a closed window-shutter, before which stands a house or a tree, and place within the darkened room a white screen at some distance from the orifice. Every straight ray proceeding from the house or tree stamps its color upon the screen, and the sum of all the rays will, therefore, be an image of the object. But, as the rays cross each other at the orifice, the image is inverted. At present we may illustrate and expand the subject thus: In front of our camera is a large opening . . . from which the lens has been removed, and which is closed at present by a sheet of tin-foil. Pricking by means of a common sewing-needle a small aperture in the tin-foil, an inverted image of the carbon-points starts forth upon the screen. A dozen apertures will give a dozen images, a hundred a hundred, a thousand a thousand. But, as the apertures come closer to each other, that is to say, as the tin-foil between the apertures vanishes, the images overlap more and more. Removing the tin-foil altogether, the screen becomes uniformly illuminated. Hence the light upon the screen may be regarded as the overlapping of innumerable images of the carbon-points. In like manner the light upon every white wall on a cloudless day may be regarded as produced by the superposition of innumerable images of the sun.—TYNDALL *Lectures on Light*, lect. 1, p. 9. (A., 1898.)

2764. PROPERTIES OF MATTER TREATED AS CAUSES—The physicist who deduces from the activities of different forms of matter certain "properties" which he attributes to them, and then uses these very "properties" to account for those activities, is obviously reasoning in a circle.—CARPENTER *Nature and Man*, lect. 15, p. 411. (A., 1889.)

2765. PROPHECY IN SCIENCE—*Spectral Lines—Foreseeing Discovery of New Planet—God Communicating with Rational Creatures.*—If the possibility of God communicating with his rational creatures be conceded, then the objections taken to prophecy lose all value. If anything known to God and unknown to man can be revealed, things past and future may be revealed as well as things present. Science abounds in prophecy. All through the geological history there have been prophetic types, mute witnesses to coming facts. Minute disturbances of heavenly bodies, altogether inappreciable by the ordinary observer, enable the astronomer to predict the discovery of new planets. A line in a spectrum, without significance to the uninitiated, foretells a new element. The merest fragment, sufficient only for microscopic examination, enables the paleontologist to describe to incredulous auditors some organism altogether unknown in its entire structures. What

possible reason can there be for excluding such indications of the past and the future from a revelation made by him who knows perfectly the end from the beginning, and to whom the future results of human actions to the end of time must be as evident as the simplest train of causes and effects is to us? [See PREDICTION.]—DAWSON *Facts and Fancies in Modern Science*, lect. 6, p. 231. (A. B. P. S.)

2766. PROPORTION BETWEEN EXTENT OF AURORA AND ITS HEIGHT— It must be noted that the extent of the aurora appears to bear a certain relation to its height. The extensive auroras—those, for instance, which are seen simultaneously in the two hemispheres—appear to shine from an immense height. On the other hand, the auroras which are at low levels are always very limited in area, or even purely local. This appears to be another point in favor of the opinion already stated, namely, that these two categories of auroras are really distinct phenomena, both in their properties and in their origin.—ANGOT *Aurora Borealis*, ch. 4, p. 56. (A., 1897.)

2767. PROSPERITY MADE POSSIBLE BY SOCIAL ORDER— *Utility of Ancient Creeds and Cults.*—Even the creeds and cults of mankind, whatever view you may take of the divine element underneath them, have been thought out and wrought out with infinite pains from time to time by earnest souls. But they had their origin in the cradle-land and in the infancy of our race. What we enjoy is only the full-blown flower, the perfected fruit of which they possessed the germ. Let me enforce this idea, as we glorify the material prosperity of the nineteenth century, that many centuries ago men sat down and with great pains and sorrow invented the language, the art, the industries, the social order which made our machines feasible and desirable.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891; Proceedings of the Congress*, p. 407).

2768. PROSPERITY OF NATIONS THE RESULT OF SCIENTIFIC PROGRESS—An equal appreciation of all branches of the mathematical, physical, and natural sciences is a special requirement of the present age, in which the material wealth and the growing prosperity of nations are principally based upon a more enlightened employment of the products and forces of Nature. The most superficial glance at the present condition of Europe shows that a diminution or even a total annihilation of national prosperity must be the award of those states who shrink with slothful indifference from the great struggle of rival nations in the career of the industrial arts. It is with nations as with Nature, which, according to a happy expression of Goethe, "knows no pause in progress and development, and attaches her curse on all inaction." The propagation of an earnest and sound knowledge of science can therefore alone avert the dangers of which I have spoken. Man cannot act upon Nature, or appropriate her forces to his own use, without comprehending their full extent and having an intimate acquaintance with the laws of the physical world.—HUMBOLDT *Cosmos*, vol. i, int., p. 53. (H., 1897.)

2769. PROTECTION BY DESTRUCTION OF ENEMIES— *The Sparrow-hawk Devours Destroyers of Crops.*—The sparrow-hawk has a perfectly clean record, as far as chickens go, not one of the 320 whose stomachs were examined by Dr. Fisher having partaken of poultry, while no less than 215 had eaten insects and 89 had captured mice. Grasshoppers are the sparrow-hawk's chief food, and we may often see him hovering over the fields with rapidly moving wings. Then, dropping lightly down on some unsuspecting victim below, he returns to the bare limb or stub he uses for a lookout station, uttering an exultant *killy—killy—killy* as he flies.—CHAPMAN *Bird-Life*, ch. 7, p. 120. (A., 1900.)

2770. PROTECTION BY DISTASTEFULNESS — *Even Parasites Avoid the Monarch Butterfly.*—Mr. Samuel H. Scudder, who has largely bred North-American butterflies, has found so many of the eggs and larvæ destroyed by hymenopterous and dipterous parasites that he thinks at least nine-tenths, perhaps a greater proportion, never reach maturity. Yet he has never found any evidence that such parasites attack either the egg or the larva of the inedible *Danais archippus*, so that in this case the insect is distasteful to its most dangerous foes in all the stages of its existence, a fact which serves to explain its great abundance and its extension over almost the whole world.—WALLACE *Darwinism*, ch. 9, p. 161. (Hum., 1897.)

2771. PROTECTION BY MIMICRY— *Spiders Resembling Leaves Both in Action and Appearance.*—Green-leafed bushes are frequented by vividly green epeiras [spiders], but the imitative resemblance does not quite end here. The green spider's method of escape, when the bush is roughly shaken, is to drop itself down on the earth where it lies simulating death. In falling, it drops just as a green leaf would drop, that is, not quite so rapidly as a round, solid body like a beetle or a spider. Now in the bushes there is another epeira, in size and form like the last, but differing in color; for instead of a vivid green it is of a faded yellowish white—the exact hue of a dead, dried-up leaf. This spider, when it lets itself drop—for it has the same protective habit as the other—falls not so rapidly as a green freshly broken-off leaf, or as the green spider would fall, but with a slower motion, precisely like a leaf withered up till it has become almost light as a

feather. It is not difficult to imagine how this comes about: either a thicker line, or a greater stiffness or tenacity of the viscid fluid composing the web and attached to the point the spider drops from, causes one to fall slower than the other.—HUDSON *Naturalist in La Plata*, ch. 14, p. 182. (C. & H., 1895.)

2772. PROTECTION IMPOSSIBLE IF NATURAL LAW NEGLECTED—*Guardian Leucocytes Powerless To Save an Enfeebled or Corrupted Organism.*—It seems probable, and, in fact, almost certain, that so long as we live in tolerably healthy conditions, these leucocytes [or white corpuscles of the blood] are able to deal with all disease-germs which can gain access to our system; but when we live in impure air, or drink impure water, or feed upon unwholesome food, our system becomes enfeebled and our guardian leucocytes are unable to destroy the disease-germs that gain access to our organism; they then increase rapidly, and are in many cases able to destroy us.—WALLACE *The Wonderful Century*, ch. 14, p. 145. (D. M. & Co., 1899.)

2773. PROTECTION OF ALPINE PLANTS BY SNOW—*The Greenhouse Proves a Fitting Substitute.*—The most striking illustration of the protection which a covering of snow affords against cold is furnished by the way in which it was at last found possible to naturalize in gardens on the continent of Europe some of the peculiarly beautiful and brilliantly colored plants of the Alpine regions, which it had often been attempted to naturalize in vain. During the winter they always died, till an ingenious gardener hit upon the device of affording them artificially the protection against cold which in their native seats they regularly obtain from their covering of snow. He did so by putting them in the greenhouses along with the orange and pomegranate trees of warmer climates, and his experiment was crowned with success. The protection which snow affords against cold is perhaps the most important function that it fulfils in the economy of Nature, but it is not its only function, nor its only important function.—CHISHOLM *Nature-Studies*, p. 30. (Hum., 1888.)

2774. PROTECTION OF EARTH BY VEIL OF VAPOR—*Freezing Power of Radiation through Dry Air.*—A freedom of escape, similar to that from bodies of vapor at great elevations, would occur at the earth's surface generally were the aqueous vapor removed from the air above it; for the great body of the atmosphere is a practical vacuum as regards the transmission of radiant heat. The withdrawal of the sun from any region over which the atmosphere is dry must be followed by quick refrigeration. The removal, for a single summer night, of the aqueous vapor from the atmosphere which covers England would be attended by the destruction of every plant which a freezing temperature could kill. The moon would be rendered entirely uninhabitable by beings like ourselves through the operation of this single cause. With a radiation uninterrupted by aqueous vapor the difference between her monthly maxima and minima must be enormous. The winters of Tibet are almost unendurable. Witness how the isothermal lines dip from the north into Asia, in winter, as a proof of the low temperature of this region. Humboldt has dwelt upon the "frigorific power" of the central portions of this continent, and controverted the idea that it was to be explained by reference to the elevation, there being vast expanses of country, not much above the sea-level, with an exceedingly low temperature. But not knowing the influence which we are now studying, Humboldt, I imagine, omitted the most potent cause of the cold. The refrigeration at night is extreme because the air is dry. In Sahara, where "the soil is fire and the wind is flame," the cold at night is often painful to bear.—TYNDALL *Heat a Mode of Motion*, lect. 13, p. 385. (A., 1900.)

2775. PROTECTION OF LABOR—*Natural Laws Inadequate—Positive Enactments Needed—The Old English Apprenticeship.*—And now for the first time appeared some of the consequences of gregarious labor under the working of natural laws, and under no restrictions from positive institution. The mill-owners collected as apprentices boys and girls, and youths and men, and women, of all ages. In very many cases no provision adequate, or even decent, was provided for their accommodation. The hours of labor were excessive. The ceaseless and untiring agency of machines kept no reckoning of the exhaustion of human nerves. The factory system had not been many years in operation when its effects were seen. A whole generation were growing up under conditions of physical degeneracy, of mental ignorance, and of moral corruption.

The first public man to bring it under the notice of Parliament with a view to remedy was, to his immortal honor, a master manufacturer, to whom the new industry had brought wealth and power and station. In 1802 the elder Sir Robert Peel was the first to introduce a bill to interfere by law with the natural effects of unrestricted competition in human labor.—ARGYLL *Reign of Law*, ch. 7, p. 207. (Burt.)

2776. PROTECTION OF TREE AGAINST LOSS OF HEAT—MM. De la Rive and De Candolle have remarked upon the influence which its feeble conducting power in a lateral direction must exert, in preserving within a tree the warmth which it acquires from the soil. But Nature has gone farther and clothes the tree with a sheathing of worse conducting material than the wood itself, even in its worst direction [viz., the bark].—TYNDALL *Heat a Mode of Motion*, lect. 9, p. 253. (A., 1900.)

2777. PROTECTION, PRECIOUSNESS OF THE DIVINE—*Human Littleness and Insecurity.*—Now, it is this littleness and this insecurity which make the protection of the Almighty so dear to us, and bring, with such emphasis, to every pious bosom the holy lessons of humility and gratitude. The God who sitteth above, and presides in high authority over all worlds, is mindful of man; and tho at this moment his energy is felt in the remotest provinces of creation, we may feel the same security in his providence as if we were the objects of his undivided care. It is not for us to bring our minds up to this mysterious agency. But such is the incomprehensible fact that the same Being, whose eye is abroad over the whole universe, gives vegetation to every blade of grass, and motion to every particle of blood which circulates through the veins of the minutest animal; that, tho his mind takes into its comprehensive grasp immensity and all its wonders, I am as much known to him as if I were the single object of his attention; that he marks all my thoughts; that he gives birth to every feeling and every movement within me, and that, with an exercise of power which I can neither describe nor comprehend, the same God who sits in the highest heaven and reigns over the glories of the firmament is at my right hand, to give me every breath which I draw and every comfort which I enjoy.—CHALMERS *Astronomical Discourses*, p. 39. (R. Ct., 1848.)

2778. PROTECTION SECURED BY THE "SLEEP" OF PLANTS—*Saving Upper Surface of Leaf from Radiation the Object Gained.*—The fact that the leaves of many plants place themselves at night in widely different positions from what they hold during the day, but with the one point in common that their upper surfaces avoid facing the zenith, often with the additional fact that they come into close contact with opposite leaves or leaflets, clearly indicates, as it seems to us, that the object gained is the protection of the upper surfaces from being chilled at night by radiation. There is nothing improbable in the upper surface needing protection more than the lower, as the two differ in function and structure. All gardeners know that plants suffer from radiation. It is this and not cold winds which the peasants of Southern Europe fear for their olives. Seedlings are often protected from radiation by a very thin covering of straw, and fruit-trees on walls by a few fir branches, or even by a fishing-net, suspended over them.—DARWIN *Power of Movement in Plants*, ch. 6, p. 284. (A., 1900.)

2779. PROTECTION THE CHIEF CARE OF NESTING BIRDS—The first step in nest-building is the selection of a site. There is almost no suitable location, from a hole in the ground to branches in the tree-tops, in which birds may not place their nests. Protection seems to be the chief desideratum, and this is generally secured through concealment. Most birds hide their nests. Many sea-birds, however, lay their eggs on the shores or cliffs, with no attempt at concealment; but, as a rule, birds that nest in this manner resort to uninhabited islets and secure protection through isolation. Some birds nest alone and jealously guard the vicinity of their home from the approach of other birds, generally of the same species. Others nest in colonies brought together by temperament or community of interests, and dwell on terms of the closest sociability.—CHAPMAN *Bird-Life*, ch. 5, p. 65. (A., 1900.)

2780. PROVISION OF NATURE FOR MAN—*The Bamboo.*—Almost all tropical countries produce bamboos, and wherever they are found in abundance the natives apply them to a variety of uses. Their strength, lightness, smoothness, straightness, roundness, and hollowness, the facility and regularity with which they can be split, their many different sizes, the varying length of their joints, the ease with which they can be cut, and with which holes can be made through them, their hardness outside, their freedom from any pronounced taste or smell, their great abundance, and the rapidity of their growth and increase, are all qualities which render them useful for a hundred different purposes, to serve which other materials would require much more labor and preparation. The bamboo is one of the most wonderful and most beautiful productions of the tropics, and one of Nature's most valuable gifts to uncivilized man. [Quoted from Wallace, "Malay Archipelago."]—MASON *Origins of Invention*, ch. 6, p. 209. (S., 1899.)

2781. PSEUDO-SCIENCE—*Comte's Second-hand Knowledge.*—As I have said, that part of M. Comte's writings which deals with the philosophy of physical science appeared to me to possess singularly little value, and to show that he had but the most superficial and merely second-hand knowledge of most branches of what is usually understood by science. I do not mean by this merely to say that Comte was behind our present knowledge, or that he was unacquainted with the details of the science of his own day. No one could justly make such defects cause of complaint in a philosophical writer of the past generation. What struck me was his want of apprehension of the great features of science; his strange mistakes as to the merits of his scientific contemporaries, and his ludicrously erroneous notions about the part which some of the scientific doctrines current in his time were destined to play in the future.—HUXLEY *Lay Sermons*, serm. 8, p. 147. (A., 1895.)

2782. PSYCHOLOGY EXPERIMENTAL—*Not Advanced by Hypnotism.*—It must, moreover, be plain to you all that there

can be no question of an experimental psychological method, in the exact sense of those words, in this matter of hypnotizing. The condition of hypnosis is such as absolutely to preclude the possibility of a psychological experiment in the real sense. The psychological experiment demands from its subject concentration of the attention, practise, skilled introspection—in short, the fulfilment of all manner of conditions, which, if not altogether and normally out of the reach of the hypnotic subject, is at least wholly impossible during the course of the induced sleep. If we compose ourselves to sleep with the intention of observing our dreams, so far as that is possible, or even if we take morphin for the same purpose, we are not making an experiment, not doing anything that in execution or result is essentially different from simple observation. The conditions of dream observation are not altered in the slightest degree by the fact that we have brought on sleep intentionally. The characteristics of the experimental method are variation and gradation of the phenomena, and elimination of certain conditions. Such a mode of procedure can be followed out in artificially induced sleep as little—or, let us say, as imperfectly—as in natural sleep; we shall gain no more by investigating the former than by collecting casual observations of normal dreams. And all this holds in still greater measure of hypnotism, since just in the cases which present the most interesting phenomena there is a total absence of any subsequent recollection. We can only infer what goes on in the mind of the somnambulist from his words and actions; if we wish to subject him to special influences we are hampered by the same conditions as hinder the investigation of sleep and dreams.—WUNDT *Psychology*, lect. 22, p. 336. (Son. & Co., 1896.)

2783. PSYCHOLOGY EXPLAINING SOCRATES—*Heroism and Self-devotion Defy Analysis—Character Known by Experience and Sympathy.*—We can say that Socrates remained in the prison because his knee muscles were contracted in a sitting position and not working to effect his escape, and that these muscle processes took place because certain psychophysical ideas, emotions, and volitions, all composed of elementary sensations, occurred in his brain, and that they, again, were the effect of all the causes which sense stimulations and dispositions, associations, and inhibitions, physiological and climatic influences, produced in that organism. And we can say, on the other hand, that Socrates remained in the prison because he decided to be obedient to the laws of Athens unto death. This obedience means, then, not a psychophysical process, but a will attitude which we must understand by feeling it and living through it, an attitude which we cannot analyze, but which we interpret and appreciate. The first is a psychological description; the second is an historical interpretation. . . . And yet both are equally true, while they blend into an absurdity if we say that those psychophysical states in the brain of Socrates were the objects which inspired the will of his pupils, and were suggestive through two thousand years.—MÜNSTERBERG *Psychology and Life*, p. 219. (H. M. & Co., 1899.)

2784. PSYCHOLOGY, FANTASIES OF COMPARATIVE METHOD IN—*Wild Statements about Children and Savages.*—There are great sources of error in the comparative method. The interpretation of the "psychoses" of animals, savages, and infants is necessarily wild work, in which the personal equation of the investigator has things very much its own way. A savage will be reported to have no moral or religious feeling if his actions shock the observer unduly. A child will be assumed without self-consciousness because he talks of himself in the third person, etc., etc. No rules can be laid down in advance. Comparative observations, to be definite, must usually be made to test some preexisting hypothesis; and the only thing, then, is to use as much sagacity as you possess, and to be as candid as you can.—JAMES *Psychology*, vol. i, ch. 7, p. 194. (H. H. & Co., 1899.)

2785. PSYCHOLOGY IN THE SCHOOLROOM—*Science Limited by an Incalculable Element—The Unknown Mind of an Opponent.*—The science of psychology, and whatever science of general pedagogics may be based on it, are, in fact, much like the science of war. Nothing is simpler or more definite than the principles of either. In war all you have to do is to work your enemy into a position from which the natural obstacles prevent him from escaping if he tries to; then to fall on him in numbers superior to his own, at a moment when you have led him to think you far away; and so, with a minimum of exposure of your own troops, to hack his force to pieces, and take the remainder prisoners. Just so, in teaching, you must simply work your pupil into such a state of interest in what you are going to teach him that every other object of attention is banished from his mind; then reveal it to him so impressively that he will remember the occasion to his dying day; and finally fill him with devouring curiosity to know what the next steps in connection with the subject are. The principles being so plain, there would be nothing but victories for the masters of the science, either on the battle-field or in the schoolroom, if they did not both have to make their application to an incalculable quantity in the shape of the mind of their opponent. —JAMES *Talks to Teachers*, ch. 1, p. 9. (H. H. & Co., 1900.)

2786. ——— ——— *Teacher Deals with Mental Life; Not with Brain Processes and Ganglion-cells—Pedagogy Independent of*

Psychological Problems.—The case of physiological psychology is the simplest one. There was never a teacher who would have taught otherwise, or would have changed his educational efforts, if the physiological substratum of the mental life had been the liver or the kidneys instead of the brain. . . . It is a caricature of the facts if you tell the teacher that he can learn anything new about the mental life if he knows by heart the accompanying brain processes; and if the teacher, in the hope of understanding the mental life of children better, studies the ganglion-cells under the microscope, he could substitute just as well the reading of Egyptian hieroglyphics.—MÜNSTERBERG *Psychology and Life,* p. 129. (H. M. & Co., 1899.)

2787. PSYCHOLOGY MUST BEGIN WITH FACTS OF CONSCIOUSNESS—*Experience As Compared with Reflection.*—If it be sensation, feeling, idea, and will which led in the first instance to the assumption of mind, the only natural method of psychological investigation will be that which begins with just these facts. First of all, we must understand their empirical nature, and then go on to reflect upon them. For it is experience and reflection which constitute each and every science. Experience comes first; it gives us our bricks; reflection is the mortar which holds the bricks together. We cannot build without both. Reflection apart from experience, and experience without reflection, are alike powerless. It is therefore essential for scientific progress that the sphere of experience be enlarged, and new instruments of reflection from time to time invented.—WUNDT *Psychology,* lect. 1, p. 8. (Son. & Co., 1896.)

2788. PSYCHOLOGY, NOTHING NEW IN ESSENTIALS OF—There is no "new psychology" worthy of the name. There is nothing but the old psychology which began in Locke's time, plus a little physiology of the brain and senses and theory of evolution, and a few refinements of introspective detail.—JAMES *Talks to Teachers,* ch. 1, p. 7. (H. H. & Co., 1900.)

2789. PUGNACITY USEFUL—*The Fighting Impulse Needed to Conquer Difficulties.*—Pugnacity need not be thought of merely in the form of physical combativeness. It can be taken in the sense of a general unwillingness to be beaten by any kind of difficulty. It is what makes us feel "stumped" and challenged by arduous achievements, and is essential to a spirited and enterprising character. We have of late been hearing much of the philosophy of tenderness in education; "interest" must be assiduously awakened in everything, difficulties must be smoothed away. *Soft* pedagogies have taken the place of the old steep and rocky path to learning. But from this lukewarm air the bracing oxygen of effort is left out. It is nonsense to suppose that every step in education *can* be interesting. The fighting impulse must often be appealed to. Make the pupil feel ashamed of being scared at fractions, of being "downed" by the law of falling bodies; rouse his pugnacity and pride, and he will rush at the difficult places with a sort of inner wrath at himself that is one of his best moral faculties. A victory scored under such conditions becomes a turning-point and crisis of his character. It represents the high-water mark of his powers, and serves thereafter as an ideal pattern for his self-imitation.—JAMES *Talks to Teachers,* ch. 7, p. 54. (H. H. & Co., 1900.)

2790. PUNCTUALITY ESSENTIAL IN SCIENTIFIC OBSERVATIONS—*Eclipse To Be Recommenced—Story of Cassini.*—It is necessary to catch them [eclipses] on the wing, so to say, and not to imitate the too presumptuous marquis of the time of Louis XV. when conducting to the observatory a party of fashionable ladies, and who, having been a little delayed by the petty cares of the toilet, arrived half a minute after the end of the eclipse. As the ladies refused to alight from their coach, a little displeased by the unreasonableness of coquetry, "Let us all go in, ladies," cried the little dandy, with the most haughty assurance; "M. de Cassini is one of my best friends, and he will have real pleasure in recommencing the eclipse for us!" This anecdote has been retold in our century on the authority of Arago.—FLAMMARION *Popular Astronomy,* bk. ii, ch. 9, p. 194. (A.)

2791. PURIFICATION OF THE ATMOSPHERE—*Deadly Gas Made to Sustain Life.*—Consider, then, all the fires in the world and all the animals in the world continually pouring their carbonic acid into the atmosphere. Would it not be fair to conclude that our air must become more and more contaminated, and unfit to support either combustion or life? This seems inevitable, but it would be a conclusion founded upon half-knowledge, and therefore wrong. A provision exists for continually purifying the atmosphere of its excess of carbonic acid. By the leaves of plants this gas is absorbed, and within the leaves it is decomposed by the solar rays. The carbon is stored up in the tree, while the pure oxygen is restored to the atmosphere. Carbonic acid, in fact, is to a great extent the nutriment of plants; and inasmuch as animals, in the long run, derive their food from the vegetable world, this very gas, which at first sight might be regarded as a deadly constituent of the atmosphere, is the main sustainer both of vegetable and animal life. —TYNDALL *Heat a Mode of Motion,* lect. 3, p. 55. (A., 1900.)

2792. PURITY, APPARENT, NOT ALWAYS REAL—*Bacteria Float in Transit through the Air—Often Where Least Expected.*—There is no numerical standard for

bacteria in the air, as there is in water. The open air possibly averages about 250 per cubic meter. On the seacoast this number would fall to less than half; in houses and towns it would rise according to circumstances, and frequently in dry weather reach thousands per cubic meter. When it is remembered *that air possesses no pabulum* for bacteria, as do water and milk, it will be understood that bacteria do not live in the air. They are only driven by air-currents from one dry surface to another. Hence the quality and quantity of air organisms depend entirely upon environment and physical conditions. In some researches which the writer made into the air of workshops in Soho in 1896, it was instructive to observe that fewer bacteria were isolated by Sedgwick's sugar-tube in premises which appeared to the naked eye polluted in a large degree than in other premises apparently less contaminated. In the workroom of a certain skin-curer the air was densely impregnated with particles from the skin, yet scarcely a single bacterium was isolated. In the polishing-room of a well-known hat firm, in which the air appeared to the naked eye to be pure, and in which there was ample ventilation, there were found four or five species of saprophytic bacteria.—Newman *Bacteria*, ch. 3, p. 107. (G. P. P., 1899.)

2793. PURITY IS SAFETY—*Germless Air Produces No Putrefaction nor Disease.*—During the ten years extending from 1859 to 1869 researches on radiant heat in its relations to the gaseous form of matter occupied my continual attention. When air was experimented on I had to cleanse it effectually of floating matter, and while doing so I was surprised to notice that, at the ordinary rate of transfer, such matter passed freely through alkalis, acids, alcohols, and ethers. The eye being kept sensitive by darkness, a concentrated beam of light was found to be a most searching test for suspended matter both in water and in air—a test, indeed, indefinitely more searching and severe than that furnished by the most powerful microscope. With the aid of such a beam I examined air filtered by cotton-wool, air long kept free from agitation, so as to allow the floating matter to subside; calcined air and air filtered by the deeper cells of the human lungs. In all cases the correspondence between my experiments and those of Schwann, Schroeder, Pasteur, and Lister in regard to spontaneous generation was perfect. The air which they found inoperative was proved by the luminous beam to be optically pure and therefore germless.—Tyndall *Floating Matter of the Air*, essay 5, p. 288. (A., 1895.)

2794. PURITY, RELATIVE, OF ANIMAL FOOD—*Meat Rarely Contains Bacteria.*—Parasites are occasionally found in meat, but bacteria are comparatively rare. Not that they do not occur in the bodies of animals used for human consumption, for in the glands, mesenteries, and other organs they are common. But in those portions of the carcass which are used by man, namely, the muscles, bacteria are rare. The reasons alleged for this are the acid reaction (sarcolactic acid) and the more or less constant movement during life. A bacterial disease which, perhaps more than any other, might be expected to be conveyed by meat is tubercle. Yet the recent Royal Commission on Tuberculosis has again emphasized the absence of bacilli in the meat substance.—Newman *Bacteria*, ch. 6, p. 234. (G. P. P., 1899.)

2795. PURPOSE, APPARENT, IN REFLEX ACTION—*The Brainless Frog.*—In observing the effects, and in reading accounts of the effects, of what is called "reflex action" in the animal economy, and before I had submitted the phrase to strict analysis, I had long felt that sense of confusion which results from the presentation to the mind of false analogies, of incompetent description, and of formulæ of expression which, pretending to be scientific, are in reality nothing but the wilful shutting-out of knowledge. It is, however, most satisfactory to find that in one of the latest and best text-books of physiology, that of Professor Forster of Cambridge, there is a full confession of the incompetency of such words as "reflex action" to describe the relation between the stimulus of an "afferent" nerve and the "efferent" movements which are carried into responsive preadjusted action. The two classes of impulse and of resulting movement are justly described as really "incommensurate." And whilst the purely mechanical or physical relation of mere bending or turning is thus condemned not only as an inadequate, but as essentially a false image of the real relation which subsists between the antecedent and the consequent phenomena, that real relation is described and admitted in the following remarkable passage: "In the more complex reflex actions of the brainless frog, and in other cases, the relation is of such a kind as that the resulting movement bears *an adaptation* to the stimulus; the foot is withdrawn from the stimulus, or the movement is calculated to push or wipe away the stimulus. In other words, a certain purpose is evident in the reflex action."—Argyll *Unity of Nature*, ch. 8, p. 302. (Burt.)

2796. PURPOSE IN NATURE—*Beauty and Utility of Dust.*—Let us now briefly summarize what we owe to the universality of dust, and especially to that most finely divided portion of it which is constantly present in the atmosphere up to the height of many miles. First of all, it gives us the pure blue of the sky, one of the most exquisitely beautiful colors in Nature. It gives us also the glories of the sunset and the sunrise, and all those brilliant hues seen in high mountain regions. Half the beauty of the world would vanish with the absence

of dust. But, what is far more important than the color of sky and beauty of sunset, dust gives us also diffused daylight, or sky-light, that most equable and soothing and useful of all illuminating agencies. Without dust the sky would appear absolutely black, and the stars would be visible even at noonday. The sky itself would, therefore, give us no light. We should have bright, glaring sunlight or intensely dark shadows, with hardly any half-tones. From this cause alone the world would be so totally different from what it is that all vegetable and animal life would probably have developed into very different forms, and even our own organization would have been modified in order that we might enjoy life in a world of such harsh and violent contrasts.—WALLACE *The Wonderful Century*, ch. 9, p. 82. (D. M. & Co., 1899.)

2797. ——— ——— *Law of Structure Subordinate to Law of Purpose—Man and Gorilla.*—Professor Huxley, in his work on "Man's Place in Nature," has endeavored to prove that, so far as mere physical structure is concerned, "the differences which separate him from the gorilla and the chimpanzee are not so great as those which separate the gorilla from the lower apes." On the frontispiece of this work he exhibits in series the skeletons of the anthropoid apes and of man. It is a grim and grotesque procession. The form which leads it, however like the others in general structural plan, is wonderfully different in those lines and shapes of matter which have such mysterious power of expressing the characters of mind. And significant as those differences are in the skeleton, they are as nothing to the differences which emerge in the living creatures. Huxley himself admits that these differences amount to "an enormous gulf," to a "divergence immeasurable —practically infinite." What more striking proof could we have than this, that organic forms are but as clay in the hands of the potter, and that the "law of structure" is entirely subordinate to the "law" of purpose and intention under which the various parts of that structure are combined for use?—ARGYLL *Reign of Law*, ch. 5, p. 157. (Burt.)

2798. ——— ——— *Manifold Adaptations—One Design No Disproof of Another—Adaptation of Grain both to Reproduction and to Food.*—To perceive intention is a very different thing from perceiving all that is intended. Our own human experience should make this distinction familiar to us. Many things we do and many things we contrive are done and contrived with more than one intention. In the light of this experience it is altogether irrational to regard as an exception to the attainment of purpose in Nature the fact, for example, "that of fifty seeds she often brings but one to bear." It throws no doubt or difficulty in the way of our conviction, for example, that one purpose of seed-bearing in plants is the reproduction of their kind, because it appears that another purpose to which that seed-bearing is applied is the support of animal life. The intention with which a grain of wheat is so constituted as to be capable of producing another wheat plant is not the less in the nature of purpose because it coexists with another intention, that the same grain should be capable of sustaining the powers and the enjoyments of life in the body and in the mind of man. On the contrary, the power possessed by most plants, and by this plant especially, of producing seed in a ratio far beyond that which would be required for one purpose, is the sure indication and the proof that another purpose larger and wider was in view.—ARGYLL *Reign of Law*, ch. 4, p. 104. (Burt.)

2799. ——— ——— *Movement of Leaves of Plants.*—As the upward movements of the leaflets of *Robinia*, and the downward movements of those of *Oxalis*, have been proved to be highly beneficial to these plants when subjected to bright sunshine, it seems probable that they have been acquired for the special purpose of avoiding too intense an illumination.—DARWIN *Power of Movement in Plants*, ch. 8, p. 453. (A., 1900.)

2800. ——— ——— *Plain Coloring of Female Birds—Final Not Identical with Physical Cause.*—Utility, indeed, in a different sense, can be quoted with probability, as accounting for the comparative plain coloring of females in this and in almost all other genera of birds. But then it is utility conceived as operating by way of motive in a creative mind, and not operating as a physical cause in the production of a mechanical result. And here we find Mr. Wallace instinctively testifying to this great distinction, and employing language which indicates the passage from one order of ideas to another. He says, "The reason why female birds are not adorned with equally brilliant plumes is sufficiently clear; they would be injurious by rendering their possessors too conspicuous during incubation." [*Quarterly Journal of Science*, October, 1867, p. 481.] This is, no doubt, the true explanation of the purpose which the plain coloring of female birds is intended to serve; but it is no explanation at all of the physical causes by which this special protection is secured.—ARGYLL *Reign of Law*, ch. 5, p. 137. (Burt.)

2801. ——— ——— *The Extermination of Useless Organisms.*—Nature is purposeful, not only in adapting recently developed structures to her uses—*i. e.*, in fitting them to perform properly the functions allotted to them—but conversely, in removing everything superfluous, so that as soon as a structure is no longer required it is eliminated. Of course, this elimination is neither sudden nor voluntary, but comes to pass

gradually, in accordance with certain laws, so that we are often able to watch every stage of the transition from the full development of an organ to the entire absence of it.—WEISMANN *Heredity,* vol. ii, ch. 9, p. 6. (Cl. P., 1891.)

2802. ——— ——— *The Key to Structure—How Darwin "Neglected This Plain Guide."*—The idea of special use, as the controlling principle of construction, is so impressed on Mr. Darwin's mind that in every detail of structure, however singular or obscure, he has absolute faith that in this lies the ultimate explanation. If an organ is largely developed, it is because some special purpose is to be fulfilled. If it is aborted or rudimentary, it is because that purpose is no longer to be subserved. In the case of another species whose structure is very singular Mr. Darwin had great difficulty in discovering how the mechanism was meant to work so as to effect the purpose. At last he made it out, and of the clue which led to the discovery he says: "The strange position of the labellum perched on the summit of the column ought to have shown me that here was the place for experiment. I ought to have scorned the notion that the labellum was thus placed *for no good purpose.* I neglected this plain guide, and for a long time completely failed to understand the flower." ["Fertilization of Orchids," p. 262.]—ARGYLL *Reign of Law,* ch. 1, p. 23. (Burt.)

2803. PURPOSE, MANIFESTED BY MONKEY—I observed to-day that if a nut or any object he [a capuchin monkey] wishes to get hold of is beyond the reach of his chain he puts out a stick to draw it towards him, or, if that does not succeed, he stands upright and throws a shawl back over his head, holding it by the two corners so that it falls down his back; he then throws it forward with all his strength, still holding on by the corners; thus it goes out far in front of him and covers the nut, which he then draws towards him by pulling in the shawl. When his chain becomes twisted round the bars of a "clothes-horse" (which is given him to run about upon), and thus too short for his comfort, he looks at it intently and pulls it with his fingers this way and that, and when he sees how the turns are taken he deliberately goes round and round the bars, first this way, then that, until the chain is quite disentangled.—ROMANES *Animal Intelligence (extract from diary of author's sister),* ch. 17, p. 486. (A., 1899.)

2804. PURPOSE MISUNDERSTOOD—*Bird Not Buoyed Up by Air-cells—Why the Bird's Bones Are Hollow.*—The common explanation of birds being assisted by air-cells for the inhalation and storage of heated air must not only be erroneous, but founded on wholly false conceptions of the fundamental mechanical principles on which flight depends. If a bird could inhale enough warm air to make it buoyant, its power of flight would be effectually destroyed. It would become as light as a balloon, and consequently as helpless. If, on the other hand, it were merely to inflate itself with a small quantity of hot air insufficient to produce buoyancy, but sufficient to increase its bulk, the only effect would be to expose it to increased resistance in cleaving the air. It is true, indeed, that the bones of birds are made more hollow and lighter than the bones of mammals, because birds, tho requiring weight, must not have too much of it. It is true, also, that the air must have access to these hollows, else they would be unable to resist atmospheric pressure. But it is no part whatever of the plan or intention of the structure of birds, or of any part of that structure, to afford balloon-space for heated air with a view to buoyancy.—ARGYLL *Reign of Law,* ch. 3, p. 87. (Burt.)

2805. PURPOSE OF CIRCULATION ON THE SUN—*The Reverse of That on the Earth.*—The solar system of circulation, instead of being adapted, like that of the earth, to the distribution of heat received from without, was seen to be directed towards the transportation towards the surface of the heat contained within. Polar and equatorial currents, tending to a purely superficial equalization of temperature, were replaced by vertical currents bringing up successive portions of the intensely heated interior mass, to contribute their share in turn to the radiation into space which might be called the proper function of a sun.—CLERKE *History of Astronomy,* pt. ii, ch. 2, p. 187. (Bl., 1893.)

2806. PURPOSE, SELECTIVE, OF HONEY-BEE—*Plan Changed to Meet Difficulties.*—Finally, in places where special conditions of the situation do not otherwise permit, it may be observed that the bees, far from clinging obstinately to their plan, very well understand how to accommodate themselves to circumstances not only in cell-building, but also in making their combs. F. Huber tried to mislead their instinct, or rather to put to the proof their reason and cleverness in every possible way, but they always emerged triumphant from the ordeal. For instance, he put bees in a hive the floor and roof of which were made of glass, that is, of a body which the bees use very unwillingly for the attachment of their combs on account of its smoothness. Thus the possibility of building as usual from above downwards, and also from below upwards, was taken away from them; they had no point of support save the perpendicular walls of their dwelling. They thereupon built on one of these walls a regular stratum of cells, from which, building sideways, they tried to carry the comb to the opposite side of the hive To prevent this, Huber covered that side also with glass. But what way out of the difficulty was found by the clever

insects? Instead of building further in the projected direction they bent the comb round at the extreme point, and carried it at a right angle towards one of the inner sides of the hive which was not covered with glass, and there fastened it. The form and dimensions of the cells must necessarily have been altered thereby, and the arrangement of their work at the angle must have been quite different from the usual. They made the cells of the convex side so much broader than those of the concave that they had a diameter two or three times as great, and yet they managed to join them properly with the others. They also did not wait to bend the comb until they came to the glass itself, but recognized the difficulty beforehand, which had been interposed by Huber while they were building with a view to overcome the first difficulty.—ROMANES *Animal Intelligence*, ch. 4, p. 177. (A., 1899.)

2807. PURPOSE THE MARK OF MIND—*Theist vs. Atheist and Materialist.*—*The pursuance of future ends and the choice of means for their attainment are the mark and criterion of the presence of mentality* in a phenomenon. We all use this test to discriminate between an intelligent and a mechanical performance. We impute no mentality to sticks and stones, because they never seem to move for *the sake of* anything, but always when pushed, and then indifferently and with no sign of choice. So we unhesitatingly call them senseless. Just so we form our decision upon the deepest of all philosophic problems: Is the Kosmos an expression of intelligence rational in its inward nature, or a brute external fact pure and simple? If we find ourselves, in contemplating it, unable to banish the impression that it is a realm of final purposes, that it exists for the sake of something, we place intelligence at the heart of it and have a religion. If, on the contrary, in surveying its irremediable flux, we can think of the present only as so much mere mechanical sprouting from the past, occurring with no reference to the future, we are atheists and materialists.—JAMES *Psychology*, vol. i, ch. 1, p. 8. (H. H. & Co., 1899.)

2808. PURPOSE WROUGHT OUT IN DISCOVERY OF AMERICA—*The Result of Scientific Thought.*—Wholly different from the first discovery of the New Continent in the eleventh century, its rediscovery by Christopher Columbus and his explorations of the tropical regions of America have been attended by events of cosmical importance, and by a marked influence on the extension of physical views. Altho the mariners who conducted this great expedition at the end of the fifteenth century were not actuated by the design of attempting to discover a new quarter of the world, and altho it would appear to be proved that Columbus and Amerigo Vespucci died in the firm conviction that they had merely touched on portions of Eastern Asia, yet the expedition manifested the perfect character of being the fulfilment of a plan sketched in accordance with scientific combinations. The expedition was safely conducted westward, through the gate opened by the Tyrians and Colæus of Samos, across the immeasurable dark sea, *mare tenebrosum*, of the Arabian geographers. They strove to reach a goal, with the limits of which they believed themselves acquainted. They were not driven accidentally thither by storms, as Naddod and Gardar had been borne to Iceland, and Gunlijörn to Greenland.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 238. (H., 1897.)

2809. PURSUIT OF THE TYPE—*The Struggle of Nature—The Ideal of Christianity.*—We have been dealing with Christianity at its most mystical point. Mark here once more its absolute naturalness. The pursuit of the type is just what all Nature is engaged in. Plant and insect, fish and reptile, bird and mammal—these in their several spheres are striving after the type. To prevent its extinction, to ennoble it, to people earth and sea and sky with it—this is the meaning of the struggle for life. And this is our life—to pursue the type, to populate the world with it.—DRUMMOND *Natural Law in the Spiritual World*, essay 8, p. 279. (H. Al.)

2810. PUTREFACTION IMPOSSIBLE IN GERMLESS AIR—*Experiments of Schwann.*—Schwann placed flesh in a flask filled to one-third of its capacity with water, sterilized the flask by boiling, and then supplied it for months with calcined air. Throughout this time there appeared no mold, no infusoria, no putrefaction: the flesh remained unaltered, while the liquid continued as clear as it was immediately after boiling. Schwann then varied his experimental argument, with no alteration in the result. His final conclusion was that putrefaction is due to decompositions of organic matter attendant on the multiplication therein of minute organisms. These organisms were derived not from the air, but from something contained in the air, which was destroyed by a sufficiently high temperature.—TYNDALL *Floating Matter of the Air*, p. 282. (A., 1895.)

2811. QUALIFICATIONS OF ARABS FOR SCIENTIFIC RESEARCH—The Arabs possessed remarkable qualifications alike for appropriating to themselves, and again diffusing abroad, the seeds of knowledge and general intercourse, from the Euphrates to the Guadalquivir, and to the south of Central Africa. They exhibited an unparalleled mobility of character, and a tendency to amalgamate with the nations whom they conquered, wholly at variance with the repelling spirit of the Israelitish castes, while, at the same time, they adhered to their national character, and the traditional recollections of their original home, notwith-

standing their constant change of abode. No other race presents us with more striking examples of extensive land journeys, undertaken by private individuals, not only for purposes of trade, but also with the view of collecting information, surpassing in these respects the travels of the Buddhist priests of Tibet and China, Marco Polo, and the Christian missionaries, who were sent on an embassy to the Mongolian princes.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 212. (H., 1897.)

2812. QUALIFICATIONS OF GREAT SCIENTIST—*Kepler—Imaginative Power Joined with Accuracy of Observation.*—My reason for more particularly naming Kepler in these remarks on the influence of direct sensuous contemplation has been to point out how, in this great and highly gifted man, a taste for imaginative combinations was combined with a remarkable talent for observation, an earnest and severe method of induction, a courageous and almost unparalleled perseverance in calculation, and a mathematical profoundness of mind, which, revealed in his "Stereometria Doliorum," exercised a happy influence on Fermat, and, through him, on the invention of the theory of the infinitesimal calculus. A man endowed with such a mind was preeminently qualified by the richness and mobility of his ideas, and by the bold cosmical conjectures which he advanced, to animate and augment the movement which led the seventeenth century uninterruptedly forward to the exalted object presented in an extended contemplation of the universe.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 327. (H., 1897.)

2813. QUALITIES, MORAL, REQUIRED IN SCIENTIFIC INVESTIGATOR—Science [early] fascinated me on its own account. To carry it duly and honestly out, moral qualities were incessantly invoked. There was no room allowed for insincerity—no room even for carelessness. The edifice of science had been raised by men who had unswervingly followed the truth as it is in Nature, and in doing so had often sacrificed interests which are usually potent in this world.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 383. (A., 1900.)

2814. QUESTIONS FOR WHICH SCIENCE HAS NO ANSWER—*Yearning a Prophecy.*—[The] notion of decay, however, implied a reference to a period, when the Matterhorn was in the full strength of mountainhood. My thoughts naturally ran back to its possible growth and origin. Nor did they halt there, but wandered on through molten worlds to that nebulous haze which philosophers have regarded, and with good reason, as the proximate source of all material things. . . . Did that formless fog contain potentially the sadness with which I regarded the Matterhorn? Did the thought which now ran back to it simply return to its primeval home? . . .

Questions like these, useless as they seem, may still have a practical outcome. For if the final goal of man has not been yet attained, if his development has not been yet arrested, who can say that such yearnings and questions are not necessary to the opening of a finer vision, to the budding and the growth of diviner powers? Without this upward force could man have risen to his present height? When I look at the heavens and the earth, at my own body, at my strength and weakness of mind, even at these ponderings, and ask myself, Is there no being or thing in the universe that knows more about these matters than I do? what is my answer?—TYNDALL *Hours of Exercise in the Alps*, ch. 24, p. 291. (A., 1898.)

2815. RACE DEPENDENT UPON SINGLE TREE—*The South-American Fan-palm.*—The *Mauritia* [fan-palm] not only affords a secure habitation, but likewise yields numerous articles of food. Before the tender spathe unfolds its blossoms on the male palm, and only at that peculiar period of vegetable metamorphosis, the medullary portion of the trunk is found to contain a sago-like meal, which, like that of the *Jatropha* root, is dried in thin bread-like slices. The sap of the tree when fermented constitutes the sweet inebriating palm-wine of the Guaranes. The narrow-scaled fruit, which resembles reddish pine-cones, yields, like the banana and almost all tropical fruits, different articles of food, according to the periods at which it is gathered, whether its saccharine properties are fully matured, or whether it is still in a farinaceous condition. Thus in the lowest grades of man's development we find the existence of an entire race dependent upon almost a single tree; like certain insects which are confined to particular portions of a flower.—HUMBOLDT *Views of Nature*, p. 13. (Bell, 1896.)

2816. RACE, IMPROVEMENT OF, BY INDIVIDUAL SELF-DISCIPLINE—Every course of intellectual and moral self-discipline, steadily and honestly pursued, tends not merely to clear the mental vision of the individual, but to ennoble the race; by helping to develop that intuitive power which arises in the first instance from the embodiment in the human constitution of the general resultants of antecedent experience, but which, in its highest form, far transcends the experience that has furnished the materials for its evolution—just as the creative power of imagination shapes out conceptions which no merely constructive skill could devise.—CARPENTER *Mental Physiology*, bk. ii, ch. 11, p. 485. (A., 1900.)

2817. RACE SLOWLY OUTGROWS CHILDISH CONCEPTION—*Stars Set in Crystal Sphere.*—It must be admitted that the idea of the stars being set in a hollow sphere of crystal, forming the vault of the

firmament, was a very natural one. They seemed to revolve around the earth every day for generation after generation without the slightest change in their relative positions. If there were no solid connection between them, it does not seem possible that a thousand bodies could move around their vast circuit for such long periods of time without a single one of them varying its distance from one of the others. It is especially difficult to conceive how they could all move around the same axis. But when they are all set in a solid sphere, every one is made secure in its place. The planets could not be set in the same sphere, because they change their positions among the stars. This idea of the sphericity of the heavens held on to the minds of men with remarkable tenacity. The fundamental proposition of the system, both of Ptolemy and Copernicus, was that the universe is spherical, the latter seeking to prove the naturalness of the spherical form by the analogy of a drop of water, altho the theory served him no purpose whatever. Faint traces of the idea are seen here and there in Kepler, with whom it vanished from the mind of the race, as the image of Santa Claus disappears from the mind of the growing child.—NEWCOMB *Popular Astronomy*, pt. i, int., p. 4. (A. B. Co.)

2818. RADIATION FROM LEAVES—*Space Draining Plants of Heat—Death of Leaves that Cannot Turn.*—We doubted at first whether radiation would affect in any important manner objects so thin as are many cotyledons and leaves, and more especially affect differently their upper and lower surfaces; for altho the temperature of their upper surfaces would undoubtedly fall when freely exposed to a clear sky, yet we thought that they would so quickly acquire by conduction the temperature of the surrounding air, that it could hardly make any sensible difference to them whether they stood horizontally and radiated into the open sky, or vertically and radiated chiefly in a lateral direction towards neighboring plants and other objects. We endeavored, therefore, to ascertain something on this head by preventing the leaves of several plants from going to sleep, and by exposing to a clear sky when the temperature was beneath the freezing-point, these, as well as the other leaves on the same plants which had already assumed their nocturnal vertical position. Our experiments show that leaves thus compelled to remain horizontal at night suffered much more injury from frost than those which were allowed to assume their normal vertical position.—DARWIN *Power of Movement in Plants*, ch. 6, p. 285. (A., 1900.)

2819. RADIATION FROM METAL AND WOOL—*Protecting Cover Should Fit Loosely.*—Here are two metal vessels, one of which is covered with lampblack, while the other is bright. Three-quarters of an hour ago boiling water was poured into them, a thermometer being placed in each. Both thermometers then showed the same temperature, but now one of them is some degrees below the other, the vessel which has cooled most rapidly being the coated one. Here, again, are two vessels, one of which is bright, and the other closely coated with flannel. Half an hour ago two thermometers, plunged in these vessels, showed the same temperature, but the covered vessel has now a temperature two or three degrees lower than the naked one. It is not unusual to preserve the heat of teapots by a woolen covering; but to be effective the "cozy" must fit very loosely. A closely fitting cover which has the heat of the teapot freely imparted to it by contact would, as we have seen, promote the loss which it is intended to diminish, and thus do more harm than good.—TYNDALL *Heat a Mode of Motion*, lect. 11, p. 299. (A., 1900.)

2820. RADIATION KEEPING PACE WITH CONTRACTION — *Would Sustain Sun's Heat for Millions of Years.*—Calculation shows that, assuming the thermal capacity of the sun to be the same as that of water, the temperature might be raised to 28,000,000 of degrees, if this quantity of heat could ever have been present in the sun at one time. This cannot be assumed, for such an increase of temperature would offer the greatest hindrance to condensation. It is probable rather that a great part of this heat, which was produced by condensation, began to radiate into space before this condensation was complete. But the heat which the sun could have previously developed by its condensation would have been sufficient to cover its present expenditure for not less than 22,000,000 of years of the past.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 181. (L. G. & Co., 1898.)

2821. RAIN, SILENT ACTION OF—*Solid Rocks Dissolved—"The Waters Wear the Stones" (Job xiv. 19).*—The most conspicuous agent employed [in the disintegration of rocks] is rain. Rain is not chemically pure, but always contains some proportion of oxygen and carbonic acid absorbed from the atmosphere; and after it reaches the ground organic acids are derived by it from the decaying vegetable and animal matter with which soils are more or less impregnated. Armed with such chemical agents, it attacks the various minerals of which rocks are composed, and thus, sooner or later, these minerals break up. . . . In all regions where rain falls the result of this chemical action is conspicuous; soluble rocks are everywhere dissolving, while partially soluble rocks are becoming rotten and disintegrated. In limestone areas it can be shown that sometimes hundreds of feet of rock have thus been gradually and silently removed from the surface of the land. And the great depth now and

again attained by rotted rock testifies likewise to the destructive action of rain-water percolating from the surface.—GEIKIE *Earth Sculpture*, ch. 2, p. 25. (G. P. P., 1898.)

2822. RAINBOW, NO PERFECT IMAGE OF IN WATER—Seeing two [rainbows], the one in the heavens, the other in the water, you might be disposed to infer that the one bears the same relation to the other that a tree upon the water's edge bears to its reflected image. The rays, however, which reach an observer's eye after reflection, and which form a bow, would, were their course uninterrupted, converge to a point vertically under the observer, and as far below the level of the water as his eye is above it. But under no circumstances could an eye above the water-level, and one below it, see the same bow—in other words, the selfsame drops of rain cannot form the reflected bow and the bow seem directly in the heavens. The reflected bow, therefore, is not, in the usual optical sense of the term, the image of the bow seen in the sky. —TYNDALL *Lectures on Light*, lect. 1, p. 26. (A., 1898.)

2823. RANGE OF THE CONDOR—*A Run Necessary for Flight—A Palisade Trap.*—This bird [the condor], which, singularly enough, like the lamas, vicuñas, alpacas, and guanacos, is not found beyond the equator in New Granada, penetrates as far south as the Straits of Magellan. In Chile, as in the elevated plateaux of Quito, the condors, which usually live in pairs, or even alone, congregate in flocks for the purpose of attacking lambs and calves, or seizing on young guanacos (guanacillos). The havoc annually committed by the condor among the herds of sheep, goats, and cattle, as well as among the wild vicuñas, alpacas, and guanacos of the chain of the Andes, is very considerable. The Chileans assert that this bird when in captivity can endure hunger for forty days; when in a free state, however, its voracity is excessive, and it then, like the vulture, feeds by preference on carrion.

The mode of catching these birds, by an enclosure of palisades. . . . is as successful in Chile as in Peru; for the bird, after being rendered heavy from excess of food, is obliged to run a short distance with half-extended wings before it can take flight. A dead ox, which is already in an incipient state of decomposition, is strongly enclosed with palisades, within which narrow space the condors throng together; being unable, as already observed, to fly on account of the excess of food which they have devoured, and impeded in their run by the palisades, these birds are either killed by the natives with clubs, or are caught alive by the lasso. The condor was represented as a symbol of strength on the coinage of Chile immediately after the first declaration of political independence.—HUMBOLDT *Views of Nature*, p. 239. (Bell, 1896.)

2824. RAYS OF STARS—*Splendor of the Heavens Increased by Optical Illusion.*—The rays of the stars disappear when the image of the radiating star is seen through a very small aperture made with a needle in a card, and I have myself frequently observed both Canopus and Sirius in this manner. The same thing occurs in telescopic vision through powerful instruments, when the stars appear either as intensely luminous points, or as exceedingly small disks. Altho the fainter scintillation of the fixed stars in the tropics conveys a certain impression of repose, a total absence of stellar radiation would, in my opinion, impart a desolate aspect to the firmament, as seen by the naked eye. Illusion of the senses, optical illusion, and indistinct vision, probably tend to augment the splendor of the luminous canopy of heaven.—HUMBOLDT *Cosmos*, vol. iii, p. 128. (H., 1898.)

2825. REACTION OF ENVIRONMENT ON MAN—*Physical Influences Have Mental Results.*—The knowledge of the character of Nature in different regions is most intimately associated with the history of the human race and its mental culture. For altho the dawn of this culture cannot have been determined solely by physical influence, climatic relations have at any rate to a great extent influenced its direction, as well as the character of nations, and the degree of gloom or cheerfulness in the dispositions of men. How powerfully did the skies of Greece act on its inhabitants! Was it not among the nations who settled in the beautiful and happy region between the Euphrates, the Halys, and the Ægean Sea that social polish and gentler feelings were first awakened? and was it not from these genial climes that our forefathers, when religious enthusiasm had suddenly opened to them the Holy Lands of the East, brought back to Europe, then relapsing into barbarism, the seeds of a gentler civilization? The poetical works of the Greeks and the ruder songs of the primitive northern races owe much of their peculiar character to the forms of plants and animals, to the mountain-valleys in which their poets dwelt, and to the air which surrounded them. To revert to more familiar objects, who is there that does not feel himself differently affected beneath the embowering shade of the beechen grove, or on hills crowned with a few scattered pines, or in the flowering meadow where the breeze murmurs through the trembling foliage of the birch? A feeling of melancholy, or solemnity, or of light, buoyant animation is in turn awakened by the contemplation of our native trees. This influence of the physical on the moral world—this mysterious reaction of the sensuous on the ideal—gives to the study of Nature, when considered from a higher point of view, a peculiar charm which has not hitherto been sufficiently recognized.—HUMBOLDT *Views of Nature*, p. 219. (Bell, 1896.)

2826. READINESS OF NERVE-CURRENTS TO FOLLOW ACCUSTOMED PATHS—*Paths Deepened as Traversed—The Power of Habit.*—Of course, a simple habit, like every other nervous event—the habit of snuffling, for example, or of putting one's hands into one's pockets, or of biting one's nails—is, mechanically, nothing but a reflex discharge, and its anatomical substratum must be a path in the system. The most complex habits . . . are, from the same point of view, nothing but concatenated discharges in the nerve-centers, due to the presence there of systems of reflex paths, so organized as to wake each other up successively, the impression produced by one muscular contraction serving as a stimulus to provoke the next, until a final impression inhibits the process and closes the chain. . . . For the entire nervous system is nothing but a system of paths between a sensory *terminus a quo* and a muscular, glandular, or other *terminus ad quem.* A path once traversed by a nerve-current might be expected to follow the law of most of the paths we know, and to be scooped out and made more permeable than before; and this ought to be repeated with each new passage of the current. . . . So nothing is easier than to imagine how, when a current once has traversed a path, it should traverse it more readily still a second time.—JAMES *Psychology,* vol. i, ch. 4, p. 107. (H. H. & Co., 1899.)

2827. READING OF CHARACTER A RARE ATTAINMENT—*Its Perfection Involves Knowledge Not Less Than Omniscient (John ii, 24).*—Even overlooking human reticence, and, what is worse, human hypocrisy, the conditions of an accurate reading of others' minds are rarely realized. If, as has been remarked by a good authority, one rarely meets, even among intelligent people, with a fairly accurate observer of external things, what shall be said as to the commonly claimed power of "intuitive insight" into other people's thoughts and feelings, as tho it were a process above suspicion? It is plain, indeed, on a little reflection, that, taking into account what is required in the way of large and varied experience (personal and social), a habit of careful introspection, as well as a habit of subtle discriminative attention to the external signs of mental life, and lastly a freedom from prepossession and bias, only a very few can ever hope even to approximate to good readers of character.—SULLY *Illusions,* ch. 9, p. 229. (A., 1897.)

2828. REALITY OF THE HUMAN SOUL—*No Ghostly Universe—Thoughts and Feelings the Surest of All Facts.*—What we call the soul, the mind, the conscious self, is something strange and wonderful. In our ordinary efforts to conceive it, invisible and impalpable as it is, we are apt to try so strenuously to divorce it from the notion of substance that it seems ethereal, unreal, ghostlike. Yet of all realities the soul is the most solid, sound, and undeniable. Thoughts and feelings are the fundamental facts from which there is no escaping. Our whole universe, from the sands on the seashore to the flaming suns that throng the Milky Way, is built up of sights and sounds, of tastes and odors, of pleasures and pains, of sensations of motion and resistance either felt directly or inferred. This is no ghostly universe, but all intensely real as it exists in that intensest of realities, the human soul!—FISKE *Through Nature to God,* pt. ii, ch. 5, p. 27. (H. M. & Co., 1900.)

2829. REASON, THE INTENTIONAL ADAPTATION OF MEANS TO ENDS—Reason or intelligence is the faculty which is concerned in the intentional adaptation of means to ends. It therefore implies the conscious knowledge of the relation between means employed and ends attained, and may be exercised in adaptation to circumstances novel alike to the experience of the individual and to that of the species.—ROMANES *Animal Intelligence,* int., p. 17. (A., 1899.)

2830. REASON WORKING FOR EVIL—*Cruel Practises Logical Results from False Premises.*—It is astonishing how reasonable—that is to say, how logical—are even the most revolting practises connected, for example, with religious worship or religious customs, provided we accept as true some fundamental conception of which they are the natural result. If it be true that the God we worship is a being who delights in suffering, and takes pleasure, as it were, in the very smell of blood, then it is not irrational to appease him with hecatombs of human victims. This is an extreme case. There are, however, such cases, as we know, actually existing in the world. But, short of this, the same principle is illustrated in innumerable cases, where cruel and apparently irrational customs are in reality nothing but the logical consequences of some fundamental belief respecting the nature, the character, and the commands of God. In like manner, in the region of morals and of conduct not directly connected with religious beliefs, reason may be nothing but the servant of desire, and in this service may have no other work to do than that of devising means to the most wicked ends. If the doctrine given to reason be the doctrine that pleasure and self-indulgence, at whatever sacrifice to others, are the great aims and ends of life, then reason will be busy in seeking out "many inventions" for the attainment of them, each invention being more advanced than another in its defiance of all obligation and in its abandonment of all sense of duty. Thus the development of selfishness under the guidance of faculties which place at its command the great powers of foresight and contrivance, is a kind of development quite as natural and quite as common as that which constitutes the growth of knowledge and of virtue. It is, indeed, a development which, under the con-

dition supposed—that is to say, the condition of false or erroneous data supplied to the reasoning faculty—is not an accident or a contingency, but a necessary and inevitable result.—ARGYLL *Unity of Nature*, ch. 10, p. 260. (Burt.)

2831. REASONING, APPARENT INSTANCE OF, AMONG BEES—*Inference Sagaciously Drawn.*—Huber gives a case of apparent exercise of reason, or power of inference from a particular case to other and general cases. A piece of comb fell down and was fixed in its new position by wax. The bees then strengthened the attachments of all the other combs, clearly because they inferred that they, too, might be in danger of falling. This is a very remarkable case, and leads Huber to exclaim, "I admit that I was unable to avoid a feeling of astonishment in the presence of a fact from which the purest reason seemed to shine out."—ROMANES *Animal Intelligence*, ch. 4, p. 185. (A., 1899.)

2832. —— —— *Intelligence Shown in Repair of Damages.*—A closely similar and therefore corroborative case [cf. 2831] of an even more remarkable kind is thus narrated in Watson's "Reasoning Power of Animals," p. 448:

"Dr. Brown, in his book on the bee, gives another illustration of the reasoning power of bees, observed by a friend of his. A center comb in a hive, being overburdened with honey, had parted from its fastenings and was pressing against another comb, so as to prevent the passage of the bees between them. This accident excited great bustle in the colony, and as soon as their proceedings could be observed it was found that they had constructed two horizontal beams between the two combs, and had removed enough of the honey and wax above them to admit the passage of a bee, while the detached comb had been secured by another beam and fastened to the window with spare wax. But what was most remarkable was that, when the comb was thus fixed, they removed the horizontal beams first constructed as being of no further use. The whole occupation took about ten days."—ROMANES *Animal Intelligence*, ch. 4, p. 185. (A., 1899.)

2833. REASONING VS. EMPIRICAL JUDGMENT—*Cloth and Dyestuff.*—Suppose I say, when offered a piece of cloth, "I won't buy that; it looks as if it would fade," meaning merely that something about it suggests the idea of fading to my mind; my judgment, tho possibly correct, is not reasoned, but purely empirical; but if I can say that into the color there enters a certain dye which I know to be chemically unstable, and that therefore the color will fade, my judgment is reasoned. The notion of the dye, which is one of the parts of the cloth, is the connecting link between the latter and the notion of fading.—JAMES *Psychology*, vol. ii, ch. 22, p. 340. (H. H. & Co., 1899.)

2834. RECITATION, VERBAL, VALUE OF—*Reaction of Mind upon Impressions.*—The older pedagogic method of learning things by rote, and reciting them parrot-like in the schoolroom, rested on the truth that a thing merely read or heard, and never verbally reproduced, contracts the weakest possible adhesion in the mind. Verbal recitation or reproduction is thus a highly important kind of reactive behavior on our impressions; and it is to be feared that, in the reaction against the old parrot recitations as the beginning and end of instruction, the extreme value of verbal recitation as an element of complete training may nowadays be too much forgotten.—JAMES *Talks to Teachers*, ch. 5, p. 34. (H. H. & Co., 1900.)

2835. RECOGNITION, A TRIUMPH OF—*Uranus Often Seen Before—Herschel Recognized It as a Planet.*—So soon as astronomers had recognized the nature of the path of Uranus, so as to be able to predict the motions of the planet, they could also trace back its course, so as to find where it had been at any given time before its discovery. Now, when this had been done, it was found that Uranus had in reality been often observed before—no less than nineteen times, in fact.

It had been observed by the eminent astronomers Flamsteed, Bradley, Mayer, and Lemonnier. Flamsteed had seen it five times, each time recording its place as that of a star of the fifth magnitude. But Lemonnier had actually seen the planet no less than twelve times. Unfortunately, Lemonnier was not an orderly man; "his astronomical papers," says one who has recently written on the subject, "are said to have been a very picture of chaos"; and M. Bouvard narrates that he had "seen one of Lemonnier's observations of this very star written on a paper-bag which had contained hair-powder." So narrowly had the planet escaped recognition until its discovery should come to reward the most laborious of all astronomers—the great Sir W. Herschel.—PROCTOR *Expanse of Heaven*, p. 117. (L. G. & Co., 1897.)

2836. RECOGNITION, MARKS THAT SERVE FOR—*Varied Colors of Birds.*—If we consider the habits and life histories of those animals which are more or less gregarious, comprising a large proportion of the herbivora, some carnivora, and a considerable number of all orders of birds, we shall see that a means of ready recognition of its own kind, at a distance or during rapid motion, in the dusk of twilight or in partial cover, must be of the greatest advantage and often lead to the preservation of life.

Among birds, these recognition marks are especially numerous and suggestive. Species which inhabit open districts are usually pro-

tectively colored; but they generally possess some distinctive markings for the purpose of being easily recognized by their kind, both when at rest and during flight. Such are the white bands or patches on the breast or belly of many birds, but more especially the head and neck markings in the form of white or black caps, collars, eye-marks or frontal patches.—WALLACE *Darwinism*, ch. 8, pp. 147-150. (Hum.)

2837. RECOGNITION, MATERNAL—*Possible Only among the Higher Animals.*—The next thing [in the evolution of motherhood] was to make it possible for the parent to recognize its young. . . . In the lower reaches the young are never in the smallest degree like their parents, and, granting the highest power of recognition to the mother, it is impossible that she should recognize her own offspring. For generations even science was imposed upon here, for many forms of life were described and classified as distinct species which have turned out to be simply the young of other species. . . . The larval forms of the starfish, or the sea-urchin, or their kinsman the holothurian are disguised past all recognition; and among the insects the relation between butterflies and moths and their respective caterpillars is beyond any possible clue. No doubt there are other modes of recognition in Nature than those which depend on the sense of sight. But looked at on every side, the fact remains that the power to identify their young is all but absent until the higher animals appear.—DRUMMOND *Ascent of Man*, ch. 8, p. 274. (J. P., 1900.)

2838. RECOGNITION OF THE IDEAL —*The First Step toward Conformity.*—The recognition of the ideal is the first step in the direction of conformity. But let it be clearly observed that it is but a step. There is no vital connection between merely seeing the ideal and being conformed to it.—DRUMMOND *Natural Law in the Spiritual World*, essay 8, p. 274. (H. Al.)

2839. RECOGNITION OF UNSEEN POWER—*Illustration of Mill Shaft.*—If we think the man foolish who supposes the main shaft of a cotton-mill to turn of itself, merely because he sees it apparently end in a wall which conceals from him the source of its motive power, are we not really chargeable with the like folly if we attribute self-motion to the ultimate molecules of matter, merely because the power that moves them is hid from our sight?—CARPENTER *Nature and Man*, lect. 12, p. 363. (A., 1889.)

2840. RECOIL OF CANNON—*Gun Heavy To Absorb Its Own Reaction.*—In constructing a cannon provision must always be made for its recoil when fired. A cannon that fires a very heavy shot must itself be heavy, for two reasons: first, in order that it may be strong enough to resist the charge of powder, and, secondly, that it may be heavy enough to absorb the reaction, so that the recoil will not be too great.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 1, p. 8. (F. H. & H., 1900.)

2841. RECONCILIATION, IRRATIONAL—*Attempt to Force Science to Accord with Supposed Biblical Teaching—Scheme of Tycho Brahe.*—There was a slight delay in the adoption of the theory of the central sun and the motion of the earth, a delay due to the astronomer Tycho Brahe, who contrived, in 1582, a mixed system susceptible of reconciling observation with the Bible, in the name of which the teaching-schools refused to accept the theory of the earth's motion.

Here is how the Danish astronomer himself states his theory:

"I think it is decidedly necessary, without any doubt, to place the earth motionless at the center of the system, according to the opinion of the ancients and the testimony of Scripture. I do not admit, with Ptolemy, that the earth may be the center of the orbits of the second 'mobile,' but I think that the celestial motions are arranged so that the moon and the sun only, with the eighth sphere, the most distant of all, and which includes all the others, have the center of their motion near the earth. The five other planets revolve round the sun as round their chief and king, and the sun must be incessantly in the midst of their orbs, which accompany him in his annual motion. . . . Thus the sun would be the ruler and end of all these revolutions, and, like Apollo in the midst of the Muses, he would rule alone all the celestial harmony."

To the system of Tycho Brahe there exists the same serious objection which was made to that of Ptolemy, since in fixing the earth at the center of the world-system he supposed that the sun, all the planets, and the whole sky of fixed stars, described round us their immense orbits in twenty-four hours. It never enjoyed a real influence.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 1, p. 343. (A.)

2842. RECONSTRUCTION FROM FRAGMENTS—*Intuitive Perception of Genius—Agassiz Rivals Exploit of Cuvier—Extinct Crustacean of Balruddery Restored.*—The numerous specimens . . . were spread out before us. . . . There were the fragments of scaly rhombs, of scaly crescents, of scaly circles, with scaly parallelograms attached to them, and of several other regular compound figures besides. . . . Agassiz glanced over the collection. One specimen especially caught his attention—an elegantly symmetrical one. It seemed a combination of the parallelogram and the crescent; there were pointed horns at each end; but the convex and concave lines of the opposite sides passed into almost parallel right lines towards the center. His eye brightened as he contemplated it. "I will tell you," he said, turning to the company—"I will tell you what these are—the remains

of a huge lobster." He arranged the specimens in the group before him with as much apparent ease as I have seen a young girl arranging the pieces of ivory or mother-of-pearl in an Indian puzzle. A few broken pieces completed the lozenge-shaped shield; two detached specimens, placed on its opposite sides, furnished the claws; two or three semirings, with serrated edges, composed the jointed body; the compound figure, which but a minute before had so strongly attracted his attention, furnished the terminal flap, and there lay the huge lobster before us, palpable to all. There is homage due to supereminent genius, which Nature spontaneously pays when there are no low feelings of envy or jealousy to interfere with her operations, and the reader may well believe that it was willingly rendered on this occasion to the genius of Agassiz.—MILLER *Old Red Sandstone*, ch. 8, p. 135. (G. & L., 1851.)

2843. RECORD, ENDURING, OF THE EVANESCENT—*Prints of Rain-drops in Geologic Rocks.*—It may be asked how any clue can be found to phenomena so evanescent as those of clouds and moisture. But do we not trace in the old deposits the rain-storms of past times? The heavy drops of a passing shower, the thick, crowded tread of a splashing rain, or the small pin-pricks of a close and fine one—all the story, in short, of the rising vapors, the gathering clouds, the storms and showers of ancient days, we find recorded for us in the fossil rain-drops; and when we add to this the possibility of analyzing the chemical elements which have been absorbed into the soil, but which once made part of the atmosphere, it is not too much to hope that we shall learn something hereafter of the meteorology even of the earliest geological ages.—AGASSIZ *Geological Sketches*, ser. i, ch. 3, p. 74. (H. M. & Co., 1896.)

2844. RECORD OF MEMORY IMPERISHABLE—*Accident May Recall What is Lost from Consciousness—The Day of Judgment.*—Accordingly, in a brain that is not disorganized by injury or disease, the organic registrations are never actually forgotten, but endure while life lasts; no wave of oblivion can efface their characters. Consciousness, it is true, may be impotent to recall them; but a fever, a blow on the head, a poison in the blood, a dream, the agony of drowning, the hour of death, rending the veil between our present consciousness and these inscriptions, will sometimes call vividly back, in a momentary flash, and call back, too, with all the feelings of the original experience, much that seemed to have vanished from the mind forever. In the deepest and most secret recesses of mind there is nothing hidden from the individual self, or from others, which may not be thus some time accidentally revealed, so that it might well be that, as De Quincey surmised, the opening of the book at the day of judgment shall be the unfolding of the everlasting scroll of memory.—MAUDSLEY *Body and Mind*, lect. 1, p. 26. (A., 1898.)

2845. RECORDS, EARLY, OF SCIENTIFIC FACT—*Eruptions of Etna.*—Etna appears to have been in activity from the earliest times of tradition, for Diodorus Siculus mentions an eruption which caused a district to be deserted by the Sicani before the Trojan war. Thucydides informs us that in the sixth year of the Peloponnesian war, or in the spring of the year 425 B. C., a lava-stream ravaged the environs of Catania, and this, he says, was the third eruption which had happened in Sicily since the colonization of that island by the Greeks. The second of the three eruptions alluded to by the historian took place in the year 475 B. C., and was that so poetically described by Pindar, two years afterwards, in his first Pythian ode. . . .

In these verses a graphic description is given of Etna, such as it appeared five centuries before the Christian era, and such as it has been seen when in eruption in modern times. The poet is only making a passing allusion to the Sicilian volcano as the mountain under which Typhœus lay buried, yet by a few touches of his master-hand every striking feature of the scene has been faithfully portrayed. We are told of "the snowy Etna, the pillar of heaven—the nurse of everlasting frost, in whose deep caverns lie concealed the fountains of unapproachable fire—a stream of eddying smoke by day, a bright and ruddy flame by night, and burning rocks rolled down with loud uproar into the sea."—LYELL *Principles of Geology*, bk. ii, ch. 25, p. 398. (A., 1854.)

2846. RECORDS, IMPERISHABLE, OF THE BABYLONIANS—*Humane Laws—Astronomical Beginnings—Cuneiform Inscriptions.*—Of the early Babylonians or Chaldeans less is known [than of the Egyptians], yet their monuments and inscriptions show how ancient and how high was their civilization. Their writing was in cuneiform or wedge-shaped characters, of which they seem to have been the inventors, and which their successors, the Assyrians, learnt from them. They were great builders of cities, and the bricks inscribed with their kings' names remain as records of their great temples, such, for instance, as that dedicated to the god of Ur, at the city known to Biblical history as Ur of the Chaldees. Written copies of their laws exist, so advanced as to have provisions as to the property of married women, the imprisonment of a father or mother for denying their son, the daily fine of a half-measure of corn levied on the master who killed or ill-used his slaves. Their astrology, which made the names of Chaldean and Baylonian famous ever since, led them to make those regular

observations of the heavenly bodies which gave rise to the science of astronomy. The nation which wrote its name thus largely in the book of civilization dates back into the same period of high antiquity as the Egyptian.—TYLOR *Anthropology*, ch. 1, p. 22. (A., 1899.)

2847. RECORDS OF ANCIENT DEAD —*Histories Self-written in the Rocks.*—Indeed, the fossil remains of all times tell us almost as much of the physical condition of the world at different epochs as they do of its animal and vegetable population. When Robinson Crusoe first caught sight of the footprint on the sand he saw in it more than the mere footprint, for it spoke to him of the presence of men on his desert island. We walk on the old geological shores, like Crusoe along his beach, and the footprints we find there tell us, too, more than we actually see in them. The crust of our earth is a great cemetery, where the rocks are tombstones on which the buried dead have written their own epitaphs. They tell us not only who they were, and when and where they lived, but much also of the circumstances under which they lived. We ascertain the prevalence of certain physical conditions at special epochs by the presence of animals and plants whose existence and maintenance required such a state of things, more than by any positive knowledge respecting it.—AGASSIZ *Geological Sketches*, ser. i, ch. 2, p. 30. (H. M. & Co., 1896.)

2848. RECORDS OF GEOLOGY—*Compared with Human Traditions.*—There is a rabbinical tradition that the sons of Tubalcain, taught by a prophet of the coming deluge, and unwilling that their father's arts should be lost in it to posterity, erected two obelisks of brass, on which they inscribed a record of his discoveries, and that thus the learning of the family survived the cataclysm. The flood subsided, and the obelisks, sculptured from pinnacle to base, were found fast fixed in the rock. Now, the twin pyramids of the Old Red Sandstone, with their party-colored bars and their thickly crowded inscriptions, belong to a period immensely more remote than that of the columns of the antediluvians, and they bear a more certain record.—MILLER *The Old Red Sandstone*, ch. 9, p. 172. (G. & L., 1851.)

2849. RED A PREVALENT COLOR IN FAUNA OF THE DEEP SEA—The fauna of the deep sea, . . . taken as a whole, is not characterized by the predominance of any one color. The shades of red occur rather more frequently than they do in the fauna of any other zone or region, but whether this is in any way connected with the fact that red is the complementary color to that of the phosphorescent light, in which many of these animals live, it is at present difficult to say; it is possible that when we have further information concerning the colors of the animals living in the deeper parts of the neritic zone another explanation may be forthcoming.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 66. (A., 1894.)

2850. REENFORCEMENT, MUTUAL —*Bacteria Gain Power by Association.*—The association of organisms . . . is . . . a fact that is rapidly becoming of the first importance in bacteriology. When species were first isolated in pure culture it was found that they behaved somewhat differently under differing circumstances. This modification in function has been attributed to differences of environment and physical conditions. Whilst it is true that such external conditions must have a marked effect upon such sensitive units of protoplasm as bacteria, it has recently been proved that one great reason why modification occurs in pure artificial cultures is that the species has been isolated from amongst its colleagues and doomed to a separate existence. One of the most abstruse problems in the immediate future of the science of bacteriology is to learn what intrinsic characters there are in species or individuals which act as a basis for the association of organisms for a specific purpose. Some bacteria appear to be unable to perform their regular function without the aid of others. An example of such association is well illustrated in the case of tetanus, for it has been shown that if the bacilli and spores of tetanus alone obtain entrance to a wound the disease may not follow the same course as when with the specific organism the lactic-acid bacillus or the common organisms of suppuration or putrefaction also gain entrance. There is here evidently something gained by association.—NEWMAN *Bacteria*, ch. 1, p. 31. (G. P. P., 1899.)

2851. REFLECTION AND JUDGMENT SHOWN BY A WASP—*Securing Facilities of Transportation.*—Th. Meenan (*Proceedings of the Acad. of Nat. Sci.*, Philadelphia, January 22, 1878) observed a case with *Vespa maculata*. He saw one of these wasps try in vain to raise from the ground a grasshopper it had killed. When all its efforts proved to be in vain it pulled its prey to a maple-tree, about thirty feet off, mounted it with its prize, and flew away from it. "This," adds the writer, "was more than instinct. It was reflection and judgment, and the judgment was proved to be correct." [It could carry the load when once raised into the air, tho it could not fly up with it.]—ROMANES *Animal Intelligence*, ch. 4, p. 197. (A., 1899.)

2852. REFLECTION AND REFRACTION—*The Two Unite to Make the Rainbow.* —A beam of solar light falling obliquely upon a rain-drop is refracted on entering the drop. It is in part reflected at the back of the drop, and on emerging it is again refracted. By these two refractions—at its entrance and at its emergence—the beam of

light is decomposed, quitting the drop resolved into colored constituents. The light thus reaches the eye of an observer facing the drop, and with his back to the sun.—TYNDALL *Lectures on Light*, lect. 1, p. 24. (A., 1898.)

2853. REFRACTION, DOUBLE, OF LIGHT—*Iceland Spar.*—Pour water and disulfid of carbon into two cups of the same depth; the cup that contains the more strongly refracting liquid will appear shallower than the other. Place a piece of Iceland spar over a dot of ink; two dots are seen, the one appearing nearer than the other to the eye. The nearest dot belongs to the most strongly refracted [the ordinary] ray, exactly as the nearest cup bottom belongs to the most highly refracting liquid. When you turn the spar round, the extraordinary image of the dot rotates round the ordinary one, which remains fixed.—TYNDALL *Lectures on Light*, lect. 3, p. 114. (A., 1898.)

2854. REFRACTION ENHANCES SENSE OF VASTNESS—*Steppes of South America.*—The distant aspect of the steppe is the more striking when the traveler emerges from dense forests, where his eye has been familiarized to a limited prospect and luxuriant natural scenery. I shall ever retain an indelible impression of the effect produced on my mind by the llanos, when, on our return from the Upper Orinoco, they first broke on our view from a distant mountain, opposite the mouth of the Rio Apure, near the Hato del Capuchino. The last rays of the setting sun illumined the steppe, which seemed to swell before us like some vast hemisphere, while the rising stars were refracted by the lower stratum of the atmosphere. When the plain has been excessively heated by the vertical rays of the sun, the evolution of the radiating heat, the ascent of currents of air, and the contact of atmospheric strata of unequal density continue throughout the night.—HUMBOLDT *Views of Nature*, p. 28. (Bell, 1896.)

2855. REFRACTION OF LIGHT—*Diminished Velocity in Denser Medium, as Glass or Water.*—According to the undulatory theory, the velocity of light in water and glass is less than in air. Consider, then, a small portion of a wave issuing from a point of light so distant that the portion may be regarded as practically plane. Moving vertically downwards, and impinging on an horizontal surface of glass or water, the wave would go through the medium without change of direction. But as the velocity in glass and water is less than the velocity in air, the wave would be retarded on passing into the denser medium. But suppose the wave, before reaching the glass, to be oblique to the surface, that end of the wave which first reaches the medium will be the first retarded by it, the other portions as they enter the glass being retarded in succession. It is easy to see that this retardation of the one end of the wave must cause it to swing round and change its front, so that when the wave has fully entered the glass its course is oblique to its original direction. According to the undulatory theory, light is thus refracted.—TYNDALL *Lectures on Light*, lect. 3, p. 109. (A., 1898.)

2856. REFRIGERATION BY EXPANSION—*Liquefaction of Oxygen, Nitrogen, Hydrogen, and Air.*—In 1877 M. Cailletet had liquefied nitric oxid and acetylene, and on the 2d of December he placed in the hands of M. Henri Saint-Claire Deville a note wherein, in cautious but distinct terms, he announced the liquefaction of oxygen. On the 16th of the same month he repeated his experiments. . . . His plan of operation involved the application of the principle of refrigeration by expansion. . . . By instruments of great strength and supreme accuracy of fit he was able to subject a volume of oxygen gas to a pressure of 300 atmospheres. He might have multiplied this pressure tenfold without liquefying the gas, but instead of augmenting the pressure he suddenly released the gas from the pressure imposed upon it. It forcibly expanded, and the cold of expansion caused the gas to precipitate itself as a cloud, which the eminent men who witnessed the experiment agreed in pronouncing liquid oxygen. He subsequently applied the same method with success to nitrogen, hydrogen, and air, all of which, through the combination of pressure with sudden release from pressure, were caused to precipitate themselves in clouds.—TYNDALL *Heat a Mode of Motion*, lect. 5, p. 145. (A., 1900.)

2857. REGELATION, FARADAY'S DISCOVERY OF—*Blocks of Ice Freeze Together under Hot Water.*—In a lecture given at the Royal Institution in June, 1850, and reported in the *Athenæum* and *Literary Gazette* for that year, Faraday showed that when two pieces of ice, at a temperature of 32° F., are placed in contact with each other they freeze together by the conversion of the film of moisture between them into ice. The case of a snowball is a familiar illustration of the principle. When the snow is below 32°, and therefore dry, it will not cohere, whereas when it is in a thawing condition it can be squeezed into a hard mass. During one of the hottest days of July, 1857, when the thermometer was upwards of 100° F. in the sun, and more than 80° in the shade, I observed a number of blocks of ice, which had been placed in a heap, frozen together at their places of contact, and I afterwards caused them to freeze together under water as hot as the hand could bear.—TYNDALL *Hours of Exercise in the Alps*, ch. 1, p. 354. (A., 1898.)

2858. RELATIVITY, LAW OF—*Different Estimates from Same Height.*—The varying judgments may perhaps be, to some extent, accounted for by that doctrine of relativity which plays so important a part in philosophy. This doctrine affirms that the impressions made upon us by any circumstance, or combination of circumstances, depend upon our previous state. Two travelers upon the same height, the one having ascended to it from the plain, the other having descended to it from a higher elevation, will be differently affected by the scene around them. To the one Nature is expanding, to the other it is contracting, and impressions which have two such different antecedent states are sure to differ. In our scientific judgments the law of relativity may also play an important part.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 123. (A., 1897.)

2859. RELICS OF A DISTANT LAND AND AGE—*Deposits of Glacial Epoch.*—On the steep slope leading from the valley of the Rhone into the Val d'Illiez, erratics [scattered boulders], formerly many hundreds, if not thousands, in number, are strewn among the vines and under the shadow of the Spanish chestnuts. They are mostly of crystalline rock, while the valley itself is wholly excavated in limestones and slates. They have been derived from various places higher up in the valley of the Rhone.—BONNEY *Ice-work, Present and Past*, pt. i, ch. 1, p. 17. (A., 1896.)

2860. RELICS OF ANCIENT PAST IN PRESENT CIVILIZATION—As the fragment of a speech or song, a waking or a sleeping vision, the dream of a vanished hand, a draft of water from a familiar spring, the almost perished fragrance of a pressed flower, call back the singer, the loved and lost, the loved and won, the home of childhood, or the parting hour, so in the same manner there linger in this crowning decade of the crowning century bits of ancient ingenuity which recall to a whole people the fragrance and beauty of its past.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891: Proceedings of the Congress*, p. 406).

2861. RELICS OF BRUTES ARE BONES AND TEETH—*Relics of Man Are Chiefly His Works—Archeology Links Geology and History.*—Nor does there appear to be any reason why those methods of examination which have proved so successful in geology should not also be used to throw light on the history of man in prehistoric times. Archeology forms, in fact, the link between geology and history. It is true that in the case of other animals we can, from their bones and teeth, form a definite idea of their habits and mode of life, while in the present state of our knowledge the skeleton of a savage could not always be distinguished from that of a philosopher. But, on the other hand, while other animals leave only teeth and bones behind them, the men of past ages are to be studied principally by their works: houses for the living, tombs for the dead, fortifications for defense, temples for worship, implements for use, and ornaments for decoration.—AVEBURY *Prehistoric Times*, ch. 1, p. 2. (A., 1900.)

2862. RELICS OF PRIMEVAL MAN—*The Old Man of Cromagnon—Cave-dwellers.*—The beautiful work of Lartet and Christy has vividly portrayed to us the antiquities of the limestone plateau of the Dordogne—the ancient Aquitania—remains which recall to us a population of Horites, or cave-dwellers, of a time anterior to the dawn of history in France, living much like the modern hunter-tribes of America, and . . . possibly contemporary—in their early history, at least—with the mammoth and its extinct companions of the later post-Pliocene forests. . . . What manner of people were they? The answer is given to us by the skeletons found in the cave of Cromagnon. This cavern is a shelter or hollow under an overhanging ledge of limestone, and excavated originally by the action of the weather on a softer bed. It fronts the southwest and the little river Vezère; and, having originally been about eight feet high and nearly twenty deep, must have formed a cozy shelter from rain or cold or summer sun, and with a pleasant outlook from its front. . . . The "Old Man of Cromagnon" was of great stature, being nearly six feet high. More than this, his bones show that he was of the strongest and most athletic muscular development—a Samson in strength: and the bones of the limbs have the peculiar form which is characteristic of athletic men habituated to rough walking, climbing, and running; for this is, I believe, the real meaning of the enormous strength of the thigh-bone and the flattened condition of the leg in this and other old skeletons. It occurs to some extent, tho much less than in this old man, in American skeletons. His skull presents all the characters of advanced age, tho the teeth had been worn down to the sockets without being lost, which, again, is the character of some, tho not of all, aged Indian skulls. The skull proper, or brain-case, is very long—more so than in ordinary modern skulls—and this length is accompanied with a great breadth, so that the brain was of greater size than in average modern men, and the frontal region was largely and well developed. . In this respect this most ancient skull fails utterly to vindicate the expectations of those who would regard prehistoric men as approaching to the apes. It is at the opposite extreme. The face, however, presented very peculiar characters. It was extremely broad, with projecting cheekbones and heavy jaw, in this resembling the coarse types of the American face, and the eye-orbits were square and elongated later-

ally. The nose was large and prominent, and the jaws projected somewhat forward. This man, therefore, had, as to his features, some resemblance to the harsher type of American physiognomy, with overhanging brows, small and transverse eyes, high cheek-bones, and coarse mouth. . . . The woman presented similar characters of stature and cranial form modified by her sex. . . . The ornaments of Cromagnon were perforated shells from the Atlantic and pieces of ivory.—DAWSON *Facts and Fancies in Modern Science*, ch. 4, p. 152. (A. B. P. S.)

2863. RELIGION AND SCIENCE NOT AT VARIANCE—*Loyalty to Truth Aids Both.*—Fully satisfied that religion and science cannot in reality be at variance, I have striven in the present publication to follow out the rule laid down by the Bishop of London in his excellent lecture delivered last year at Edinburgh. The man of science," says Dr. Tait, ought to go on, " honestly, patiently, diffidently, observing and storing up his observations, and carrying his reasonings unflinchingly to their legitimate conclusions, convinced that it would be treason to the majesty at once of science and of religion if he sought to help either by swerving ever so little from the straight rule of truth."—AVEBURY *Prehistoric Times*, pref., p. 9. (A., 1900.)

2864. RELIGION IMPREGNABLE IN THE ESTIMATE OF SCIENCE—*Herbert Spencer.*—" How truly its central position is impregnable," Herbert Spencer has well discerned, " religion has never adequately realized. In the devoutest faith, as we habitually see it, there lies hidden an innermost core of skepticism, and it is this skepticism which causes that dread of inquiry displayed by religion when face to face with science." True indeed; religion has never realized how impregnable are many of its positions.—DRUMMOND *Natural Law in the Spiritual World*, int., p. 26. (H. Al.)

2865. RELIGION MEETS NATURAL WANT — *General Craving of Man.* —This world of ours has, on the whole, been an inclement region for the growth of natural truth; but it may be that the plant is all the hardier for the bendings and buffetings it has undergone. The torturing of a shrub, within certain limits, strengthens it. Through the struggles and passions of the brute, man reaches his estate; through savagery and barbarism his civilization; and through illusion and persecution, his knowledge of Nature, including that of his own frame. The bias towards natural truth must have been strong to have withstood and overcome the opposing forces. Feeling appeared in the world before knowledge, and thoughts, conceptions, and creeds, founded on emotion, had, before the dawn of science, taken root in man. Such thoughts, conceptions, and creeds must have met a deep and general want, otherwise their growth could not have been so luxuriant, nor their abiding power so strong.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 373. (A., 1900.)

2866. RELIGION, MINGLING OF, WITH SCIENCE UNDESIRABLE—*Nebular Hypothesis Unsustained.*—It has indeed always seemed to me a circumstance to be regretted that religious questions should have been in any way associated with the scientific difficulties involved in this particular question [the nebular hypothesis]. There is always this objection to such associations, that, in forming them, we are apt to associate scientific errors with religious teachings, and these truths seem to suffer when the scientific errors are exposed. Thus well-meaning men have again and again injured the cause they were most eager to serve, by calling in to its aid unsuitable allies. But altho I can see no religious reasons for casting discredit on the theory that processes have gone on and are going on upon an infinitely vast scale, resembling those which we see daily going on around us upon a finite scale, yet it does appear to me that there are many excellent scientific reasons for doubting very gravely whether all the suns which people space were originally formed from masses of glowing gas.—PROCTOR *Our Place among Infinities*, p. 230. (L. G. & Co., 1897.)

2867. RELIGION MORE THAN SENSE OF DEPENDENCE—*Definition Includes the Thing To Be Defined.*—The definitions of religion have been even worse than the definitions of morality. Just as the attempt is made to account for morals apart from the sense of duty or of obligation in conduct, so is the attempt made to account for religion apart from the sense of mind or will in Nature. The great effort seems to have been to try how the essential idea of religion could be either most completely eliminated or else most effectually concealed. For example, a feeling of absolute dependence has been specified by Schleiermacher as the essence of religion. Yet it is evident that a sense of absolute dependence may be urgent and oppressive without the slightest tincture of religious feeling. A man carried off in a flood and clinging to a log of wood may have, and must have, a painful sense of absolute dependence on the log. But no one would think of describing this sense as a feeling of religion. . . . Any plausibility, therefore, which may attach to the proposition which identifies religion with the mere sense of dependence is due entirely to the fact that when men speak of a sense of dependence they suggest the idea of a particular kind of dependence—namely, dependence upon a being or a personality, and not dependence upon a thing. That is to say, that the plausibility of the definition is entirely due to an element of thought which it is specially framed to keep out of sight.—ARGYLL *Unity of Nature*, ch. 11, p. 267. (Burt.)

2868. RELIGION, ORIGIN AND MANIFESTATION OF—*Danger Awakens Religious Instinct.*—As long as no real danger threatens, we may laugh at the religious instinct, because it has no opportunity to act. But as soon as danger approaches it acts even in unbelievers.—DAHL *Die Nothwendigkeit der Religion eine letzte Consequenz der Darwinschen Lehre.* (Translated for *Scientific Side-Lights.)*

2869. RELIGION, PRIMEVAL, UNFOUNDED SPECULATION CONCERNING—*The One Element Common to All Religions—Worship of Superhuman Personality.*—Primeval man has kept no journal of his own first religious emotions, any more than of his own first appearance in the world. We are therefore thrown back upon pure speculation—speculation, indeed, which may find in the present, and in a comparatively recent past, some data for arriving at conclusions, more or less probable, on the conditions of a time which is out of sight. But among the very first of these data—if it be not, indeed, the one datum without which all others are useless—is a clear conception of the element which is common to all religions as they exist now, or as they can be traced back beyond the dawn of history into the dim twilight of tradition. Of this universal element in all religions "the Infinite" is no definition at all. It is itself much more vague and indefinite in meaning than the word which it professes to explain. And this is all the more needless, seeing that the common element in all religions, such as we know them now, is one of the greatest simplicity. It is the element of a belief in superhuman beings—in living agencies other and higher than our own.—ARGYLL *Unity of Nature*, ch. 11, p. 274. (Burt.)

2870. RELIGION, SCIENCE A HELPER OF—*Extension of Knowledge Leads to Higher Faith.*—In proportion as religion avails herself of the help of science and its labors to strengthen her position and power, so will she most typically and admirably fulfil her great office in ruling wisely and well the inner and higher life of man. As science progresses, so let religion advance with her; for the world, we shall find, is daily awakening to new beliefs, to the fuller knowledge of itself. The great, irresistible tide of human knowledge is sweeping away the old landmarks and resting-places with rapid force. And wise indeed are they who, recognizing the extension of knowledge as from God, betake themselves with the tide to higher levels of thought, and there construct their dwelling-places anew.—ANDREW WILSON *Science-Culture for the Masses*, p. 35. (Hum., 1888.)

2871. RELIGION, UNIVERSALITY OF—The universality of religion, its existence among all known peoples, may be regarded as indubitable evidence that its appearance is owing to necessary causes.—DAHL *Die Nothwendigkeit der Religion eine letzte Consequenz der Darwinschen Lehre.* (Translated for *Scientific Side-Lights.)*

2872. ——— ——— *No Adequate Evidence of Tribes without Religion.*—On one main point which has been questioned respecting existing facts the progress of inquiry seems to have established beyond any reasonable doubt that no race of men now exists so savage and degraded as to be, or to have been when discovered, wholly destitute of any conceptions of a religious nature. It is now [1883] well understood that all the cases in which the existence of such savages has been reported are cases which break down upon more intimate knowledge and more scientific inquiry.

Such is the conclusion arrived at by a careful modern inquirer, Professor Tiele, who says: "The statement that there are nations or tribes which possess no religion rests either on inaccurate observations or on a confusion of ideas. No tribe or nation has yet been met with destitute of belief in any higher beings, and travelers who asserted their existence have been afterwards refuted by facts. It is legitimate, therefore, to call religion, in its most general sense, an universal phenomenon of humanity."—ARGYLL *Unity of Nature*, ch. 11, p. 281. (Burt.)

2873. RENEWAL AFTER EXHAUSTION—*Impediments to New Action Removed—Sundew Leaf Dried to Clear It of Remains—Reanointing for Capture of Prey.*—As soon as tentacles which have remained closely inflected during several days over an object begin to reexpand, their glands secrete less freely, or cease to secrete, and are left dry. In this state they are covered with a film of whitish, semifibrous matter, which was held in solution by the secretion. The drying of the glands during the act of reexpansion is of some little service to the plant; for I have often observed that objects adhering to the leaves could then be blown away by a breath of air, the leaves being thus left unencumbered and free for future action. Nevertheless, it often happens that all the glands do not become completely dry; and in this case delicate objects, such as fragile insects, are sometimes torn by the reexpansion of the tentacles into fragments, which remain scattered all over the leaf. After the reexpansion is complete the glands quickly begin to resecrete, and as soon as full-sized drops are formed the tentacles are ready to clasp a new object.—DARWIN *Insectivorous Plants*, ch. 1, p. 13. (A., 1900.)

2874. REPAIR COMPENSATES WASTE—*Sleep Nature's Opportunity of Restoration.*—Repair is everywhere and always making up for waste. Tho the two processes vary in their relative rates, both are constantly going on. Tho during the active, waking state of an animal waste is in excess

of repair, yet repair is in progress; and tho during sleep repair is in excess of waste, yet some waste is necessitated by the carrying-on of certain never-ceasing functions. The organs of these never-ceasing functions furnish, indeed, the most conclusive proofs of the simultaneity of repair and waste. Day and night the heart never stops beating, but only varies in the rapidity and vigor of its beats, and hence the loss of substance which its contractions from moment to moment entail must from moment to moment be made good. Day and night the lungs dilate and collapse, and the muscles which make them do this must therefore be kept in a state of integrity by a repair which keeps pace with waste, or which alternately falls behind and gets in advance of it to a very slight extent.—SPENCER *Biology*, pt. ii, ch. 4, p. 216. (A., 1900.)

2875. REPOSE IS DEATH—*Knowledge and Progress from Action.*—Some years ago I found myself in discussion with a friend who entertained the notion that the general tendency of things in this world is towards equilibrium, the result of which would be peace and blessedness to the human race. My notion was that equilibrium meant not peace and blessedness, but death. No motive power is to be got from heat, save during its fall from a higher to a lower temperature, as no power is to be got from water save during its descent from a higher to a lower level. Thus also life consists, not in equilibrium, but in the passage towards equilibrium. . . . In times of strife and commotion we may long for peace, but knowledge and progress are the fruits of action.—TYNDALL *New Fragments*, p. 10. (A., 1897.)

2876. REPOSE SUCCEEDING STRESS AND STRAIN—*Quiet Hills the Remains of Once Vast Volcanoes—The British Isles Volcanic.*—In Devonian or Old Red Sandstone times, volcanic activity was renewed with fresh violence upon that part of the earth's surface now occupied by the British Islands. Along the line which now forms the Grampians there rose a series of volcanoes of the very grandest dimensions. Ben Nevis, and many others among the higher Scotch mountains, have been carved by denudation from the hard masses of granite, quartz-felsite, and other Plutonic rocks which formed the central cores of these ancient volcanic piles. The remains of the great lava-sheets and of the masses of volcanic agglomerate ejected from these grand Devonian volcanoes make up hill ranges of no mean altitude.—JUDD *Volcanoes*, ch. 10, p. 274. (A., 1899.)

2877. REPOSE SUGGESTED BY ASPECT OF STARS—*Vast and Swift Motion the Contrasted Fact.*—The motions taking place within the star-system are also altogether amazing when rightly apprehended. Contemplating the stars on a still night, the idea of infinite repose is suggested by their serenity of aspect. Judging the stars again by the ordinary tests of motion, the astronomers of old had abundant reason to regard them as the very emblems of fixity. But in the light of modern astronomical research, we have this lesson forced upon us, that every one of these bright orbs, and all the millions that are unseen save by telescopically strengthened vision, are urging their way so swiftly through space that the most rapid motions familiar to us must be regarded as absolute rest by comparison. We know with what startling rapidity an express train rushes past a quiet country station. In its swift motion and heavy mass it seems the embodiment of might and energy. Yet the swiftest express train moves but at the rate of about one mile in a minute of time, and its bulk is utterly insignificant compared with that of the smallest member of the solar system. What inconceivable energy must we recognize, then, in the motion of our sun through space, at a rate of hundreds of miles per minute, the whole of his attendant family (each member of which is traveling rapidly around him) accompanying him in his swift rush through the interstellar depths! Yet even this wonderful energy of motion seems little when compared with the flight of Sirius, an orb a thousand times larger than the sun, and traveling many times more swiftly. And we have abundant reasons for believing that amongst the stars revealed by powerful telescopes there are thousands as large as Sirius, and millions as large as our sun—all with their attendant systems speeding with inconceivable rapidity on their several courses!—PROCTOR *Our Place among Infinities*, p. 232. (L. G. & Co., 1897.)

2878. REPRODUCTION OF BACTERIA—*Almost Incredible Fertility—Checks upon Their Increase.*—Their minute size would make them harmless enough if it were not for an extraordinary power of multiplication. This power of growth and division is almost incredible. Some of the species which have been carefully watched under the microscope have been found under favorable conditions to grow so rapidly as to divide every half-hour or even less. The number of offspring that would result in the course of twenty-four hours at this rate is of course easily computed. In one day each bacterium would produce over 16,500,000 descendants, and in two days about 281,500,000,000. It has been further calculated that these 281,500,000,000 would form about a solid pint of bacteria and weigh about a pound. At the end of the third day the total descendants would amount to 47,000,000,000,000, and would weigh about 16,000,000 pounds. Of course these numbers have no significance, for they are never actual or even possible numbers. Long before the offspring reach even into the millions their rate of multiplication is

checked either by lack of food or by the accumulation of their own excreted products, which are injurious to them. But the figures do have interest, since they show faintly what an unlimited power of multiplication these organisms have, and thus show us that in dealing with bacteria we are dealing with forces of almost infinite extent.—CONN *Story of Germ Life*, ch. 1, p. 21. (A., 1900.)

2879. ——— ——— *Growth of Yeast —The Budding of a Plant (Matt. xiii, 33).*—Budding, division, and spore-formation are the three chief ways in which [bacteria] reproduce their kind. Budding occurs in some kinds of yeast. . . . The capsule of a large or mother-cell shows a slight protrusion outwards, which is gradually enlarged into a daughter-yeast and later on becomes constricted at the neck. Eventually it separates as an individual. The protoplasm of spores of yeast differs, as Hansen has pointed out, according to their conditions of culture.—NEWMAN *Bacteria*, ch. 1, p. 16. (G. P. P., 1899.)

2880. RESERVE OF POWER—*Physical Endurance without Food.*—On the eastern end of the ridge [of the Matterhorn] we halted to take a little food; not that I seemed to need it—it was the remonstrance of reason rather than the consciousness of physical want that caused me to do so.

Facts of this kind illustrate the amount of force locked up in the muscles which may be drawn upon without renewal. I had quitted London ill, and when the Matterhorn was attacked I was by no means well. In fact, this climb was one of the means adopted to drive the London virus from my blood. The day previous I had taken scarcely any food; and on starting from the cabin half a cup of bad tea, without any solid whatever, constituted my breakfast. Still, during the five hours' climb from the cabin to the top of the Matterhorn, tho much below par physically and mentally, I felt neither faint nor hungry. This is an old experience of mine upon the mountains. The Weisshorn, for example, was climbed on six meat lozenges, tho it was a day of nineteen hours. Possibly this power of long-continued physical effort, without eating, may be a result of bad digestion which deals out stingily, and therefore economically, to the muscles the energy of the food previously consumed.—TYNDALL *New Fragments*, p. 491. (A., 1897.)

2881. ——— ——— *The Sun's Energy Stored in Wood or Coal Operative after Any Lapse of Years.*—The sun [has] locked up in each tree a store of energy thousands of times greater than that which was spent in merely lifting the trunk from the ground, as we may see by unlocking it again when we burn the tree under the boiler of an engine; for it will develop a power equal to the lifting of thousands of its kind, if we choose to employ it in this way. This is so true that the tree may fall and turn to coal in the soil, and still keep this energy imprisoned in it—keep it for millions of years till the black lump under the furnace gives out, in the whirling spindles of the factory or the turning-wheel of the steamboat, the energy gathered in the sunshine of the primeval world.—LANGLEY *New Astronomy*, ch. 3, p. 73. (H. M. & Co.)

2882. RESISTANCE TO INFECTION —*Some Persons Insusceptible.*—There is ample evidence in support of the fact that not all the persons partaking of infected food suffer equally, and occasionally some escape altogether. We know little or nothing of the causes of such modification in the effect produced. It may be due to other organisms, or chemical substances already in the alimentary canal of the individual, or it may be due to some insusceptibility or resistance of the tissues. Be that as it may, it is a matter which must not be neglected in estimating the effects of food contaminated with bacteria or their products.—NEWMAN *Bacteria*, ch. 6, p. 180. (G. P. P., 1899.)

2883. RESOLVES STRENGTHENED BY ACTION—*Motor Effects in Brain Endure —Practical Opportunity the Fulcrum of Moral Power.*—Seize the very first possible opportunity to act on every resolution you make, and on every emotional prompting you may experience in the direction of the habits you aspire to gain. It is not in the moment of their forming, but in the moment of their producing motor effects, that resolves and aspirations communicate the new "set" to the brain. As the author last quoted [Bahnsen] remarks:

"The actual presence of the practical opportunity alone furnishes the fulcrum upon which the lever can rest, by means of which the moral will may multiply its strength and raise itself aloft. He who has no solid ground to press against will never get beyond the stage of empty gesture-making."—JAMES *Psychology*, vol. i, ch. 4, p. 124. (H. H. & Co., 1899.)

2884. RESPIRATION IN RAREFIED AIR—*Man at Great Heights—Wonderful Power of Condor.*—Ulloa, more than a hundred years ago, expressed his astonishment that the vulture of the Andes could soar at heights where the pressure of the atmosphere was less than fifteen inches. An opinion was at that time entertained, from the analogy of experiments made with the air-pump, that no animal could exist under this slight amount of atmospheric pressure. I have myself . . . seen the barometer fall to 14.85 inches on the Chimborazo; and my friend, M. Gay-Lussac, breathed for a quarter of an hour an atmosphere in which the pressure was only 12.9 inches. It must be admitted that man, when wearied by muscular exertion, finds himself in a state

of painful exhaustion at such elevations; but in the condor the respiratory process seems to be performed with equal facility under a pressure of 30 or of 13 inches. This bird probably raises itself voluntarily to a greater height from the surface of our earth than any other living creature. I use the expression "voluntarily," since small insects and silicious-shelled infusoria are frequently borne to greater elevations by a rising current of air. It is probable that the condor flies even higher than the above calculations would appear to show.—HUMBOLDT *Views of Nature*, p. 238. (Bell, 1896.)

2885. RESPIRATION IS COMBUSTION—*Food Supplies Fuel—Three Classes of Food Necessary.*—Respiration is a true example of combustion. The seat of the combustion is the lungs. The substance burnt is sugar. The products are carbonic dioxid gas and water. The materials of animal food may be divided into three classes: non-nitrogenized substances, such as starch and sugar; nitrogenized substances, like lean meat and eggs, and lastly, fatty substances, like butter. . . . No article of food which does not contain all three of these classes of substances can alone support life for any length of time. A man would starve to death on starch alone, on meat alone, or on butter alone. The relative proportion, however, in which these three classes of substances are required by man depends on his outward circumstances, such as the climate, his physical activity, his occupation, or his peculiar temperament, and to the right balance of his food he is guided by experience.—COOKE *Religion and Chemistry*, ch. 4, p. 104. (S., 1894.)

2886. RESPONSE TO HUMAN FEELINGS SOUGHT IN NATURE—Every imaginative mind looks for reflections of its own deepest feelings in the world about it. The lonely, embittered heart, craving for sympathy, which he cannot meet with in his fellow man, finds traces of it in the sighing of the trees or the moaning of the sad sea wave. Our poet laureate, in his great elegy, has abundantly illustrated this impulse of the imagination to reflect its own emotional coloring on to inanimate things: for example, in the lines:

> The wild unrest that lives in woe
> Would dote and pore on yonder cloud
> That rises upward always higher,
> And onward drags a laboring breast,
> And topples round the dreary west,
> A looming bastion fringed with fire.
> [TENNYSON *In Memoriam*, st. 15, l. 15.]

—SULLY *Illusions*, ch. 9, p. 226. (A., 1897.)

2887. RESPONSIBILITY DESTROYED OR TRANSFERRED—Anything which destroys responsibility or transfers it cannot be other than injurious in its moral tendency and useless in itself.—DRUMMOND *Natural Law in the Spiritual World*, essay 10, p. 325. (H. Al.)

2888. RESPONSIBILITY FOR MENTAL ILLUSIONS — *Coleridge's Unbelief in Ghosts—Resolution Can Hold the Mind to Realities.*—If we only choose to exert ourselves we can always keep our illusions in a nascent or imperfectly developed stage. This applies not only to those half-illusions into which we voluntarily fall, but also to the more irresistible passive illusions, and those arising from an over-excited imagination. Even persons subject to hallucinations, like Nicolai of Berlin, learn to recognize the unreal character of these phantasms. On this point the following bit of autobiography from the pen of Coleridge throws an interesting light. "A lady" (he writes) "once asked me if I believed in ghosts and apparitions. I answered with truth and simplicity, 'No, madam, I have seen far too many myself.'" However irresistible our sense-illusions may be, so long as we are under the sway of particular impressions or mental images, we can, when resolved to do so, undeceive ourselves by carefully attending to the actual state of things about us.—SULLY *Illusions*, ch. 6, p. 125. (A., 1897.)

2889. RESPONSIBILITY OF THE DRUNKARD—*Abstinence a Possibility and a Duty—Ruin Is Criminal Insanity.*—Whatever allowances society may be ready to make for individual cases—such, for instance, as that of Hartley Coleridge, who was the victim of a strong hereditary predisposition, accompanied by a constitutional weakness of will—it recognizes as a fixed conviction, and consistently acts upon that conviction, that the incipient drunkard has a power over himself; that he can not only abstain if he chooses, but that he can choose to abstain because he knows that he ought to do so; and that when, by voluntarily giving way to his propensity, he brings himself into a condition in which he is no more responsible for his actions than a lunatic, he is not thereby exempted from the penalty that may attach to them, but must be held responsible for having knowingly and deliberately brought himself into the condition of irresponsibility. — CARPENTER *Mental Physiology*, pref., p. 42. (A., 1900.)

2890. REST DUE TO A BALANCE OF FORCES—*Duration and Indestructibility of Matter.*—All that we know of matter is inseparably connected with the forces which it exerts, or which it is capable of exerting, or which are being exerted in it. The force of gravitation seems to be all-pervading, and to be either an inherent power or property in every kind, or almost every kind of matter, or else to be the result of some kind of energy which is universal and unquenchable. All bodies, however passive and inert they may seem to be under certain conditions, yet indicate by their very existence the power of those molecular forces to which the cohesion of their atoms is due. The fact is now familiar to us that the most

perfect stillness, and apparent rest, in many forms of matter is but the result of a balance or equilibrium maintained between forces of the most tremendous energy, which are ready to burst forth at a moment's notice, when the conditions are changed under which that balance is maintained. And this principle, which has become familiar in the case of what are called explosive substances, because of the ease and the certainty with which the balanced forces can be liberated, is a principle which really prevails in the composition of all material substances whatever, the only difference being that the energies by which their molecules are held together are so held under conditions which are more stable—conditions which it is much more difficult to change—and conditions, therefore, which conceal from us the universal prevalence and power of force in the constitution of the material universe. It is, therefore, distinctly the tendency of science more and more to impress us with the idea of the unlimited duration and indestructible nature both of matter and of the energies which work in it and upon it.—ARGYLL *Unity of Nature*, ch. 4, p. 80. (Burt.)

2891. REST, UNREAL — *Parasitism Not Christian.*—Whatever rest is provided by Christianity for the children of God, it is certainly never contemplated that it should supersede personal effort. And any rest which ministers to indifference is immoral and unreal — it makes parasites and not men.—DRUMMOND *Natural Law in the Spiritual World*, essay 9, p. 301. (H. Al.)

2892. RESULT, COMBINATION TO SECURE—*Force of Association in Memory—All Circumstances Must Converge upon Hidden Thought.*—The writer of these pages has every year to learn the names of a large number of students who sit in alphabetical order in a lecture-room. He finally learns to call them by name as they sit in their accustomed places. On meeting one in the street, however, early in the year, the face hardly ever recalls the name, but it may recall the place of its owner in the lecture-room, his neighbors' faces, and consequently his general alphabetical position; and then, usually, as the common associate of all these combined data, the student's name surges up in his mind. A father wishes to show to some guests the progress of his rather dull child in kindergarten instruction. Holding the knife upright on the table, he says, "What do you call that, my boy?" "I calls it a knife, I does," is the sturdy reply, from which the child cannot be induced to swerve by any alteration in the form of question, until the father recollecting that in the kindergarten a pencil was used, and not a knife, draws a long one from his pocket, holds it in the same way, and then gets the wished-for answer, "I calls it vertical." All the concomitants of the kindergarten experience had to recombine their effect before the word "vertical" could be reawakened.—JAMES *Psychology*, vol. i, ch. 14, p. 568. (H. H. & Co., 1899.)

2893. RESULT, VAST, FROM SMALL EXPERIMENTS—*Soda from Sea-salt.*—As a single example out of a thousand, take the manufacture of carbonate of soda from sea-salt, more than 200,000 tons of which, of the value of two millions sterling, are annually made in the alkali works of Great Britain. The salt is first converted into sulfate of soda by the action of sulfuric acid; the sulfate of soda is then converted into carbonate of soda by being heated with chalk and carbon. This important substance was formerly manufactured from barilla, and the interesting chemical process now employed on so gigantic a scale was the result of an experiment with substances heated in an evaporating-dish by means of a spirit-lamp.—LOWE *Nature-Studies*, p. 1. (Hum., 1888.)

2894. RESULTS ATTAINED, DUE APPRECIATION OF—It is true that our plummet is not long enough to measure the depths of the sea, but that is no reason why it should lose value for us; if it helps us for the time being to avoid the rocks and the sand-banks, that service is great enough. —LIEBIG *Vorrede zur Thierchemie.* (Translated for *Scientific Side-Lights.)*

2895. RESULTS, NATURAL TO SEEK —*Return Impression Completes Cycle of Activity.*—It would seem only natural to say that, since after acting we normally get some return impression of result, it must be well to let the pupil get such a return impression in every possible case. Nevertheless, in schools where examination marks and "standing" and other returns of result are concealed, the pupil is frustrated of this natural termination of the cycle of his activities, and often suffers from the sense of incompleteness and uncertainty; and there are persons who defend this system as encouraging the pupil to work for the work's sake, and not for extraneous reward. Of course, here, as elsewhere, concrete experience must prevail over psychological deduction. But, so far as our psychological deduction goes, it would suggest that the pupil's eagerness to know how well he does is in the line of his normal completeness of function, and should never be balked except for very definite reasons indeed.—JAMES *Talks to Teachers*, ch. 5, p. 37. (H. H. & Co., 1900.)

2896. RESULTS NOT ACCOUNTED FOR—*Structure of Organic Beings Not Explained by External Conditions.*—It is preposterous to attribute to mere external conditions the structure, for instance, of the woodpecker, with its feet, tail, beak, and tongue so admirably adapted to catch insects under the bark of trees. In the case of the mistletoe, which draws its nourish-

ment from certain trees, which has seeds that must be transported by certain birds, and which has flowers with separate sexes absolutely requiring the agency of certain insects to bring pollen from one flower to the other, it is equally preposterous to account for the structure of this parasite, with its relations to several distinct organic beings, by the effects of external conditions, or of habit, or of the volition of the plant itself.—DARWIN *Origin of Species*, int., p. 3. (Burt.)

2897. RESULTS OF DISTANT CAUSES—*Coal Deposits.*—We find in certain localities subterranean deposits of coal, consisting of vegetable matter, formerly drifted into seas and lakes. These seas and lakes have since been filled up, the lands whereon the forests grew have disappeared or changed their form, the rivers and currents which floated the vegetable masses can no longer be traced, and the plants belonged to species which for ages have passed away from the surface of our planet. Yet the commercial prosperity and numerical strength of a nation may now be mainly dependent on the local distribution of fuel determined by that ancient state of things. —LYELL *Principles of Geology*, ch. 1, p. 2. (A., 1854.)

2898. RESULTS OUTREACHING NARROW LIMITS—*The Mediterranean in History—True Conception of Plato.*—Plato, in his "Phædo," describes the narrow limits of the Mediterranean in a manner that accords with the spirit of enlarged cosmical views. "We, who inhabit the region extending from Phasis to the Pillars of Hercules, occupy only a small portion of the earth," he writes, "where we have settled ourselves round the inner sea like ants or frogs round a swamp." This narrow basin, on the borders of which Egyptian, Phenician, and Hellenic nations flourished and attained to a high degree of civilization, is the point from which the most important historical events have proceeded, no less than the colonization of vast territories in Africa and Asia, and those maritime expeditions which have led to the discovery of the whole western hemisphere of the globe.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 119. (H., 1897.)

2899. RESULTS, SECONDARY, MOST PERNICIOUS — *Bacteria Poison by Their Products—Toxins—Ptomaines.* — From the careful study of a number of epidemics due to food poisoning, this patient observer [Dr. Ballard] was able, without the aid of modern bacteriology, to arrive at a simple principle which must not be forgotten. Food poisoning is due either to bacteria themselves or to their products, which are contained in the substance of the food. In cases of the first kind, bacteria gaining entrance to the human alimentary canal, set up their specific changes and produce their toxins, and by so doing in course of time bring about a diseased condition, with its consequent symptoms. On the other hand, if the products, sometimes called *ptomaines*, are ingested as such, the symptoms set up by their action in the body tissues appear earlier. From these facts Dr. Ballard deduced the simple principle that if there is no incubation period, or at all events a comparatively short space of time between eating the poisoned food and the advent of disease, the agents of the disease are products of bacteria. If, on the other hand, there is an incubation period, the agents are probably bacteria.—NEWMAN *Bacteria*, ch. 6, p. 176. (G. P. P., 1899.)

2900. RESULTS UNINTENDED—*Bradley — Herschel — Fraunhofer—Columbus.*—This method of measuring the distance of the stars by the effect of perspective due to the annual displacement of the earth had already been divined by the astronomers of the last century, and in particular by Bradley, who, in attempting to measure the distance of the stars by observations made at intervals of six months, found another thing. Instead of discovering the distance of the stars, which was the object of his observations, he discovered a very important optical phenomenon—the aberration of light, an effect produced by the combination of the velocity of light with the earth's motion in space. His case was similar to that of William Herschel, who, in searching for the parallax of stars by comparisons between bright stars and their near companions, found the double-star systems; or, like Fraunhofer, who, in seeking the limits of the colors of the solar spectrum, found the rays of absorption, the study of which founded spectrum analysis. The history of the sciences shows us that discoveries have very often been made by researches which are only indirectly related to them. In attempting to reach by the west the eastern frontiers of Asia, Christopher Columbus discovered the New World. He might not have discovered it, and he might not have looked for it, if he had known the true distance from Portugal to Kamchatka.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 5, p. 594. (A.)

2901. ——— ——— *Descartes Supporting Materialism—Animals as Automata—Why Not Man the Same?*—When Descartes denied mind to animals, on the ground that the essence of mind consists in thought, and man is the only thinking being, he could have little imagined that this proposition would do as much as the strictly mechanical views which he represented in natural philosophy to further the doctrines which are the direct opposite of the spiritualism which he taught—the doctrines of modern materialism. If animals are natural automata, and if all the phenomena which general belief refers to sensation, feeling, and will are the result of purely mechanical conditions, why should not the same explana-

tion hold of man? This was the obvious inference which the materialism of the seventeenth and eighteenth centuries drew from Descartes's principles.—WUNDT *Psychology*, lect. 1, p. 5. (Son. & Co., 1896.)

2902. ——— ——— *Indefatigable Patience Rewarded—Quest in One Line Leads to Discovery of a Different Kind.*—Indeed, Schwabe himself was far from anticipating the discovery which fell to his share. He compared his fortune to that of Saul, who, seeking his father's asses, found a kingdom. For the hope which inspired his early resolution lay in quite another direction. His patient ambush was laid for a possible intramercurial planet, which, he thought, must sooner or later betray its existence in crossing the face of the sun. He took, however, the most effectual measures to secure whatever new knowledge might be accessible. During forty-three years his "imperturbable telescope" never failed (weather and health permitting) to bring in its daily report as to how many, or if any, spots were visible on the sun's disk, the information obtained being day by day recorded on a simple and unvarying system. In 1843 he made his first announcement of a probable decennial period [of sun-spots].—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 156. (Bl., 1893.)

2903. ——— ——— *Machinery Improving Weeds—Difficulty of Cleansing Wheat Increased.*—L. H. Dewey, in the *Year-book* of the Department of Agriculture for the year 1896, p. 276, says: "Cockle-seeds are normally somewhat smaller than wheat-grains. In some parts of the Northwest, where wheat for sowing has been cleaned year after year by steam thrashers, all the cockle-seeds except the largest ones have been removed, and these have been sown until a large-seeded strain has been bred which is very difficult to separate from the wheat."—BEAL *Seed Dispersal*, ch. 8, p. 81. (G. & Co., 1898.)

2904. RESULTS, UNNOTICED, OF QUIET, PERSISTENT ACTION—*Thermal Springs Bring Material from Depths of the Earth.*—Nor are thermal springs by any means ineffective agents in bringing material from the interior of the earth's crust and depositing it at the surface. The Bath spring contains various saline substances, principally sulfates and chlorids, in solution in its waters. These are quietly carried by rivers to the sea, and are lost to our view. The spring has certainly maintained its present condition since the time of the Romans, and I find that if the solid materials brought from the interior of the earth during the last 2,000 years had been collected they would form a solid cone equal in height to Monte Nuovo. Yet we usually regard the Campi Phlegræi as a powerfully active volcanic district, and the subterranean action in our own country as quite unworthy of notice.—JUDD *Volcanoes*, ch. 8, p. 219. (A., 1899.)

2905. REVELATION ALLOWS ROOM FOR NATURAL LAW—*"The Dust of the Ground."*—But what of revelation? Are its history and doctrines incompatible with the belief that God uniformly acts through the use of means? The narrative of creation is given to us in abstract only, and is told in two different forms, both having apparently for their main, perhaps their exclusive, object the presenting to our conception the personal agency of a living God. Yet this narrative indicates, however slightly, that room is left for the idea of a material process. "Out of the dust of the ground"—that is, out of the ordinary elements of Nature—was that body formed which is still upheld and perpetuated by organic forces acting under the rules of law. Nothing which science has discovered or can discover is capable of traversing that simple narrative.—ARGYLL *Reign of Law*, ch. 1, p. 16. (Burt.)

2906. REVELATION OF GOD IN NATURE—It is a noble object that invites us to these annual gatherings. Leaving the broils of the world to others, we come to contemplate together the teachings of God in Nature. We come with faith in that word which is written around and within us, believing in the truthfulness of the revelation, and knowing that he who approaches it with an inquiring, teachable spirit, ever wakeful to the still, small voice, and forgetful of ambitious self, shall find the truth, and feel its benign influence. We aim to decipher some new words in the volume of Nature, that we may learn the will of Him who has ordered all things well, and comprehend more fully his laws in the government of the universe.—DANA *Address as President of the Association for 1854* (*Proceedings of the Amer. Assoc. for the Advancement of Science, 1855*, vol. ix, p. 1).

2907. REVELATION OF THE UNKNOWN—*Depths of Sea Till Lately Unexplored.*—The bottom of the deep sea was until quite recently one of the *terræ incognitæ*. It was regarded by most persons, when it entered into their minds to consider it at all, as one of those regions about which we do not know anything, never shall know anything, and do not want to know anything.—HICKSON *Fauna of the Deep Sea*, pref., p. 7. (A., 1894.)

2908. REVELATIONS OF THE SPECTROSCOPE—*Stars Proved To Be Suns—Minerals Found in the Stars—Unity of the Universe—Stars and Nebulæ Discriminated.*—The immediate effect of the application of the spectroscope to the stars was very striking. The supposition that they were suns became a certainty, since they gave spectra similar in character and often very closely resembling in detail that of our sun. Aldebaran is one of the most sunlike stars, being yellow in color and possessing lines which indicate most of the elements found in the sun. White stars,

such as Sirius and Vega, show hydrogen lines only; and these are supposed to be hotter than our sun, and in an earlier stage of development, while red stars are supposed to be cooling. Other explanations of these facts have, however, been suggested. Much information has also been obtained as to the nature of the nebulæ. Sir William Herschel supposed that they were all really star-clusters, but so enormously remote that even the most powerful telescopes could not render visible the stars composing them. Later observations have shown that many of them do consist of stars, or star-dust, as it has been called; and this seemed to support the theory that all were so composed, including the Milky Way. A study of the distribution of stars and nebulæ by Proctor and others led, however, to the conclusion that they were often really connected, and that nebulæ were not, on the average, more distant than stars: and this view has been confirmed by the spectroscope, which has shown them often to consist of glowing gas; and this is especially the characteristic of all those situated in or near the Milky Way. The first great result of spectrum analysis has thus been to demonstrate the real nature of many stars and nebulæ, to determine some of the elements of which they are formed, and to give us some indications of the changes they have undergone, and thus help us toward a general theory of the development of the stellar universe.—WALLACE *The Wonderful Century*, ch. 6, p. 43. (D. M. & Co., 1899.)

2909. REVELATIONS OF THE TELESCOPE FRAGMENTARY—*Each View but of a Narrow Field—A Human Eye with Telescopic Power Could Get the Perspective of the Heavens—Science Seeks to Present Such a Scene to the Mind's Eye.*—If the human eye could suddenly obtain the power of telescopic vision, those wealths of star-strewing which it is the province of star-gaging to measure would be revealed to our view, not piecemeal, as under telescopic scrutiny, but at once as in a grand celestial panorama. Those varieties of distribution to which Herschel applied his resolution test would be clearly recognized. Here the stars would be seen spread richly over a region of the heavens, but clearly separated from each other; elsewhere would be regions where the stars would more closely cluster, tho still separately discernible; but in parts of the heavens veritable star-clouds would be seen, regions where the stars gather so closely together that even the enhanced powers of vision I have imagined—nay, tho the power of the Rosse telescope had been acquired by man —would fail to show discrete stars, the sky in those parts being aglow with condensed starlight, on which, as on a splendid background, brighter stars would be seen spread with inconceivable richness.

Such a scene might not be intelligible at a first view; it might even baffle all attempts at interpretation, all efforts to estimate the relative distances and proportions of its several parts. But our only path to the solution of the noblest problem in science is by presenting to the mind's eye such a picture of the great star-strewn sphere which surrounds us on all sides; when that has been done we shall begin to know whether the great problem is altogether beyond our mastery.—PROCTOR *Expanse of Heaven*, pp. 262-3. (L. G. & Co., 1897.)

2910. REVERENCE FOR ANTIQUITY—*Decline of, under Modern Civilization.*—The whole country [of Denmark] appears to have been, at one time, thickly studded with tumuli; where the land has not been brought into cultivation, many of them are often in sight at once, and even in the more fertile and thickly populated parts the plow is often diverted from its course by one of these ancient burial-places. Fortunately, the stones of which they are constructed are so large and so hard that their destruction and removal is a laborious and expensive undertaking. While, however, on the one hand, land grows gradually more valuable, and the stones themselves are more and more coveted for building or other purposes; on the other, the conservative traditions, the feeling of superstitious reverence for the dead, which have so long protected them from desecration, is gradually becoming weaker; and it is estimated that not a day passes without witnessing the destruction of one or more of these tumuli, and the loss of some, perhaps almost irrecoverable, link in the history of the human race.—AVEBURY *Prehistoric Times*, ch. 7, p. 213. (A., 1900.)

2911. REVERENCE GROWS WITH KNOWLEDGE OF NATURE — *Sublimity Not the Product of Ignorance.*—The fear [is] entertained by some persons that Nature may by degrees lose a portion of the charm and magic of her power as we learn more and more how to unveil her secrets. . . . It is true that, properly speaking, the forces of Nature can only exercise a magical power over us as long as their action is shrouded in mystery and darkness, and does not admit of being classed among the conditions with which experience has made us acquainted. The effect of such a power is, therefore, to excite the imagination, but that, assuredly, is not the faculty of mind we would evoke to preside over the laborious and elaborate observations by which we strive to attain to a knowledge of the greatness and excellence of the laws of the universe. The physical philosopher measures with admirable sagacity the waves of light of unequal length which by interference mutually strengthen or destroy each other, even with respect to their

chemical actions; the astronomer, armed with powerful telescopes, penetrates the regions of space, contemplates, on the extremest confines of our solar system, the satellites of Uranus, or decomposes faintly sparkling points into double stars differing in color. The botanist discovers the constancy of the gyratory motion of the chara in the greater number of vegetable cells, and recognizes in the genera and natural families of plants the intimate relations of organic forms. The vault of heaven, studded with nebulæ and stars, and the rich vegetable mantle that covers the soil in the climate of palms, cannot surely fail to produce on the minds of these laborious observers of Nature an impression more imposing and more worthy of the majesty of creation than on those who are unaccustomed to investigate the great mutual relations of phenomena. I cannot, therefore, agree with Burke when he says, "it is our ignorance of natural things that causes all our admiration, and chiefly excites our passions."—HUMBOLDT *Cosmos*, vol. i, int., p. 39. (H., 1897.)

2912. REVERSAL OF GENERAL RULE—*Snow-line Highest on Northern Slope of Himalayas—Monsoons Pile Waters of Indian Ocean on the Southern Side of the Mountains.*—Since the time of Humboldt attention has frequently been drawn to the fact that in those mountains [the Himalayas] the snow-line is higher on the north or colder side than on the southern and therefore warmer slopes. The amount of the difference has been variously estimated by various observers, but there appears to be no doubt of the fact that the relative difference is as stated, not the reverse. And it is not difficult to understand why it should be so. The southern slopes, tho the warmer, are exposed to the moisture-laden monsoons which blow from the south during half the year in India, and at a certain elevation this moisture is precipitated in the form of snow. The northern slopes, on the other hand, are swept only by the comparatively dry winds that have crossed the interior of Asia, and hence the accumulations of snow in the course of the year are immensely greater on the south side than on the north. On the former side the power of the sun on the Himalayas, just as on the Alps, is greater in causing the snow to disappear, but as there is much more snow on that side to be removed in the intervals between the deposition of fresh snow, the line up to which its total disappearance can be effected is lower there than on the north.—CHISHOLM *Nature-Studies*, p. 34. (Hum., 1888.)

2913. REVERSION IN AGE TO FAULTS OF YOUTH—*Deep Meaning of Second Childhood—Importance of Early Impressions.*—The science of statistics shows that certain crimes which are common in the seasons of youth disappear, comparatively, with advancing age, and reappear again toward the close of life; or, in other words, that the tendencies to indulgences in disorders of imagination, and habits which were acquired in the early life of a vicious youth, or one exposed to evil associations, tho they may be masked and kept in subjection by the judgment and the influences of position and reputation during early manhood, middle life, and first decline, resume their sway and close the career of the man who has perhaps for years sustained a spotless reputation—with ignominy and shame. How frequently do cases of this kind present themselves! I have now in my mind's eye an individual who for forty years was known and esteemed as a model of honor, purity, and integrity, but who at the age of seventy committed a crime which consigned his name to infamy. Depend upon it, this man was subjected to evil influences in early life, and the impressions then made, tho neutralized by the conditions and circumstances which afterwards surrounded him, were never effaced, and, when the latter ceased to produce their restraining effects, the former resumed their original sway. Pursuing this train of thought we would conclude that the child is not merely the father of the man, but, more emphatically, the father of the old man; that the term "second childhood" has a more extended signification than that of the mere decline of the faculties. It also should convey the idea that the tendency of the dispositions and propensities of individuals is to return to the condition of earlier life.—HENRY *Thoughts on Education* (*Scientific Writings*, vol. i, p. 341). (Sm. Inst., 1886.)

2914. REVERSION TO ANCESTRAL FORMS—*Enduring Power of Type—The Stripe in Horses.*—By the term "reversion" or "atavism" we understand the remarkable fact known to all breeders of animals, that occasionally single and individual animals assume a form which has not existed for many generations, but belongs to a generation which has long since disappeared. One of the most remarkable instances of this kind is the fact that in some horses there sometimes appear singular dark stripes, similar to those of the zebra, quagga, and other wild species of African horses. Domestic horses of the most different races and of all colors sometimes show such dark stripes: for example, a stripe along the back, a stripe across the shoulders, and the like. The sudden appearance of these stripes can only be explained by the supposition that it is the effect of a latent transmission, a relapse into the ancient original form, which has long since vanished, and was once common to all species of horses; the original form, undoubtedly, was originally striped like the zebras, quaggas, etc. —HAECKEL *History of Creation*, vol. i, ch. 9, p. 214. (K. P. & Co., 1899.)

2915. REVOLUTION IN ASTRONOMY—*New Centering of the Solar System by Copernicus.*—The fundamental views of Copernicus have indicated to theoretical astronomy paths which could not fail to lead to sure results. . . . "By no other arrangement," he exclaims with enthusiasm, "have I been able to find so admirable a symmetry of the universe, and so harmonious a connection of orbits, as by placing the lamp of the world *(lucernam mundi)*, the Sun, in the midst of the beautiful temple of Nature as on a kingly throne, ruling the whole family of circling stars that revolve around him *(circumagentem gubernans astrorum familiam)*." Even the idea of universal gravitation or attraction *(appetentia quædam naturalis partibus indita)* toward the sun as the center of the world *(centrum mundi)*, and which is inferred from the force of gravity in spherical bodies, seems to have hovered before the mind of this great man, as is proved by a remarkable passage in the 9th chapter of the 1st book [of] "De Revolutionibus."—HUMBOLDT *Cosmos*, vol. ii, pt. ii, pp. 305, 308. (H., 1897.)

2916. REWARDS OF EARLY INVENTORS—*The First Patent.*—The earliest invention was a single homogeneous act, an original suggestion, a happy thought. The patent on this was an immediate and individual benefit. A sharper knife of flint, a better scraper, a longer spear, a stouter thread wrought better, and the reward was more execution. Now, the man who made the best weapons killed the most game, from that game he got better food, that food made him stronger, that strength made him chief, that chieftaincy gave him more wives, more children, more cohorts to support his throne. The best woman to cook or sew or carry loads got the best husband; that was her patent. From these simple methods of inventing and rewarding invention we come on to the Olympic games, the monopolies, the patent system. And now, in the inventor's laboratory of Graham Bell or Edison the climax is reached, where one machine is the cooperative result of any number of trained minds, and the reward is meted out to each by the manufacturer.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891; Proceedings of the Congress*, p. 411).

2917. RHYTHM OF THOUGHT LIKE PERIODS OF LANGUAGE—*Intervals between Sentences Full of Meaning.*—As we take, in fact, a general view of the wonderful stream of our consciousness, what strikes us first is this different pace of its parts. Like a bird's life, it seems to be made of an alternation of flights and perchings. The rhythm of language expresses this, where every thought is expressed in a sentence, and every sentence closed by a period. The resting-places are usually occupied by sensorial imaginations of some sort, whose peculiarity is that they can be held before the mind for an indefinite time, and contemplated without changing; the places of flight are filled with thoughts of relations, static or dynamic, that for the most part obtain between the matters contemplated in the periods of comparative rest.—JAMES *Psychology*, vol. i, ch. 9, p. 243. (H. H. & Co., 1899.)

2918. RICHES OF CREATIVE POWER INEXHAUSTIBLE—*Wonderfully Varied Light of Colored Suns.*—The colors of the double stars, then, are real, so that if we could pay a visit to one of these pairs we should find colored suns—red, orange, and yellow ruling suns, and green, purple, or blue minor suns, or, as the case might be, lilac, puce, mauve, russet, or olive suns of the smaller sort. Nor must we think of these smaller suns as really small in themselves. It is only by comparison with the leading orbs of unequal pairs that the lesser is called small. In reality it is probable that many of the lesser suns of these double systems are very much larger than all the planets of the solar system together.—PROCTOR *Expanse of Heaven*, p. 222. (L. G. & Co., 1897.)

2919. RICHES OF SCIENCE NOT TO BE WASTED—*Revelation of Nature Must Help Religion.*—It is impossible to believe that the amazing succession of revelations in the domain of Nature during the last few centuries, at which the world has all but grown tired wondering, are to yield nothing for the higher life. If the development of doctrine is to have any meaning for the future, theology must draw upon the further revelation of the seen for the further revelation of the unseen. It need, and can, add nothing to fact; but as the vision of Newton rested on a clearer and richer world than that of Plato, so, tho seeing the same things in the spiritual world as our fathers, we may see them clearer and richer. With the work of the centuries upon it, the mental eye is a finer instrument, and demands a more ordered world.—DRUMMOND *Natural Law in the Spiritual World*, int., p. 29. (H. Al.)

2920. RIDDLE OF ATTRACTION OF AMBER—*Dawning Study of Electricity.*—The sphinx of the centuries follows the flies and the reptiles into the golden recesses of the amber, and there enthroned poses once more the nature of the amber soul as a new riddle. There is no kinship between this evanescent energy drawn from these yellow depths and the stolid pull of the dull stone, no similarity between the wayward and mastering spirit which seizes upon anything within its strength and the unrelenting tyranny with which the magnet enforces servitude only upon the stubborn iron. What, then, is this genius which is called forth by the friction of the amber,

even as the afrit was summoned by the rubbing of Aladdin's lamp? Thus the question first asked twenty-two hundred years before was renewed, and now impressed with greater urgency than ever upon the newly awakened human intellect [in the sixteenth century].—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 9, p. 252. (J. W., 1898.)

2921. RIGHT WINS ITS OWN CONQUEST—*Will Has Only To Hold It Steadily at the Front.*—When our impulsive feeling is hot . . . it is hard to hold the right idea steadily enough before the attention to let it exert its adequate effects. Whether it be stimulative or inhibitive, it is too reasonable for us; and the more instinctive passional propensity then tends to extrude it from our consideration. We shy away from the thought of it. It twinkles and goes out the moment it appears in the margin of our consciousness, and we need a resolute effort of voluntary attention to drag it into the focus of the field, and to keep it there long enough for its associative and motor effects to be exerted. . . . Once brought, however, in this way to the center of the field of consciousness and held there, the reasonable idea will exert these effects inevitably; for the laws of connection between our consciousness and our nervous system provide for the action then taking place. Our moral effort, properly so called, terminates in our holding fast to the appropriate idea.—JAMES *Talks to Teachers*, ch. 15, p. 186. (H. H. & Co., 1900.)

2922. RISE AND FALL OF ANCIENT LANDS—*Forests Submerged—New Vegetation Succeeding (Ps. cvii, 33, 35).*—In some of the deeper coal-beds there is a regular alternation between layers of coal and layers of sand or clay; in certain localities as many as ten, twelve, and even fifteen coal-beds have been found alternating with as many deposits of clay or mud or sand; and in some instances, where the trunks of the trees are hollow and have been left standing erect, they are filled to the brim, or to the height of the next layer of deposits, with the materials that have been swept over them. Upon this set of deposits comes a new bed of coal with the remains of a new forest, and above this again a layer of materials left by a second freshet, and so on through a number of alternate strata. It is evident from these facts that there has been a succession of forests, one above another, but that in the intervals of their growth great floods have poured over the marshes, bringing with them all kinds of loose materials, such as sand, pebbles, clay, mud, lime, etc., which, as the freshets subsided, settled down over the coal, filling not only the spaces between such trees as remained standing, but even the hollow trunks of the trees themselves.—AGASSIZ *Geological Sketches*, ser. i, ch. 3, p. 84. (H. M. & Co., 1896.)

2923. RISE IN GRADE OF LIFE—*Insect Life Shows the Gradation.*—Take a homely and very familar example, that of the branch of articulates. Naturalists divide this branch into three classes—Insects, *Crustacea*, and Worms; and most of them tell you that worms are lowest, *Crustacea* next in rank, and that insects stand highest, while others have placed the *Crustacea* at the head of the group. We may well ask why. Why does an insect stand above a crustacean, or vice versa; why is a grasshopper or a butterfly structurally superior to a lobster or a shrimp? . . . But when we study the gradual development of the insect, and find that in its earliest stages it is wormlike, in its second, or chrysalis stage, it is crustacean-like, and only in its final completion it assumes the character of a perfect insect, we have a simple natural scale by which to estimate the comparative rank of these animals.—AGASSIZ *Journey in Brazil*, ch. 1, p. 21. (H. M. & Co.)

2924. RIVERS CLARIFIED BY PASSING THROUGH LAKES—*Purity of Niagara's Torrent—The Rhone Flows Clear from Lake of Geneva.*—The fact that bodies of standing water retain the mineral matter brought to them in suspension is illustrated more or less perfectly in nearly every lake and pond, and even by ephemeral pools by the wayside, but is especially marked in great seas like those drained by the St. Lawrence. During storms all of the streams pouring into the upper Laurentian lakes, from the surface drainage of the land, are brown and heavy with mud, but the water rushing over Niagara remains of the same deep greenish-blue tint season after season and year after year. Niagara River, above the falls, and the St. Lawrence, are surface streams, because their clear waters have but slight power of corrasion; it is for this reason that during the centuries they have occupied their present channels they have not materially deepened them.

In the case of lakes fed by the turbid waters from glaciers the part they play as settling-basins is even more strikingly shown than in the instances just cited. Lake Geneva, Switzerland, fed by the silt-laden waters of the Rhone, is discolored for several miles from where the river enters, but when the waters leave the lake and again start on their journey they are wonderfully clear. An abundance of similar illustrations is furnished by the glacial-fed lakes of the Sierra Nevada and Cascade mountains and by some of the numerous lakes on the head waters of the Yukon.—RUSSELL *Lakes of North America*, ch. 2, p. 39. (G. & Co., 1895.)

2925. RIVERS IN THEIR WILD STATE—*Maps Change from Year to Year.*—The greatest changes are shown by rivers in their wild state—that is, where they divide into numerous arms and may be said to dissolve into separate veins, as may be

witnessed wherever a stream plunges from the mountains immediately into a plain. The Rhine runs wild as it enters the upper Rhine plateaux, the Bode does the same at the north foot of the Harz, the Inn as it forsakes the Alps. Throughout such regions scarcely a year elapses without one arm or another disappearing, while other branches are formed. Successive maps, therefore, show very different pictures of the stream.—PEUCK *Oberflächenbau, Anleitung zur Landes- und Volksforschung*, p. 29. (Translated for *Scientific Side-Lights.)*

2926. RIVERS IN THE OCEAN—*The Gulf Stream.*—The narrow currents or true oceanic rivers which traverse the sea bring warm water into higher and cold water into lower latitudes. To the first class belongs the celebrated Gulf Stream, which was known to Anghiera, and more especially to Sir Humphrey Gilbert in the sixteenth century. Its first impulse and origin are to be sought to the south of the Cape of Good Hope; after a long circuit it pours itself from the Caribbean Sea and the Mexican Gulf through the Straits of the Bahamas, and, following a course from south-southwest to north-northeast, continues to recede from the shores of the United States, until, further deflected to the eastward by the banks of Newfoundland, it approaches the European coasts, frequently throwing a quantity of tropical seeds *(Mimosa scandens, Guilandina bonduc, Dolichos urens)* on the shores of Ireland, the Hebrides, and Norway. The northeastern prolongation tends to mitigate the cold of the ocean, and to ameliorate the climate on the most northern extremity of Scandinavia.—HUMBOLDT *Cosmos,* vol. i, p. 307. (H., 1897.)

2927. RIVERS LIFTED BY THE SUN—*Heat Restored in Downward Flow.*—Late discoveries have taught us that winds and rivers have their definite thermal values, and that, in order to produce their motion, an equivalent amount of solar heat has been consumed. While they exist as winds and rivers, the heat expended in producing them has ceased to exist, being converted into mechanical motion; but when that motion is arrested, the heat which produced it is restored. A river, in descending from an elevation of 7,720 feet, generates an amount of heat competent to augment its own temperature 10° F., and this amount of heat was abstracted from the sun, in order to lift the matter of the river to the elevation from which it falls. As long as the river continues on the heights, whether in the solid form as a glacier or in the liquid form as a lake, the heat expended by the sun in lifting it has disappeared from the universe. It has been consumed in the act of lifting. But at the moment that the river starts upon its downward course, and encounters the resistance of its bed, the heat expended in its elevation begins to be restored. The mental eye, indeed, can follow the emission from its source; through the ether as vibratory motion; to the ocean, where it ceases to be vibration, and assumes the potential form, among the molecules of aqueous vapor; to the mountain-top, where the heat absorbed in vaporization is given out in condensation, while that expended by the sun in lifting the water to that elevation is still unrestored. This we find paid back to the last unit: by the friction along the river's bed; at the bottom of the cascades where the plunge of the torrent is suddenly arrested; in the warmth of the machinery turned by the river; in the spark from the millstone; beneath the crusher of the miner [or] in the Alpine sawmill.—TYNDALL *Heat a Mode of Motion,* lect. 17, p. 527. (A., 1900.)

2928. RIVERS OF ICE—*The Glacier Flows Like a Stream—No Sharp Line Divides Different States of Matter.*—As might be expected from these varied phenomena, it has been found that there is no such sharp line of distinction between the various states of matter as is popularly supposed; some of the properties which are characteristic of matter in one state being present in a less degree in other states. Viscous bodies, for example, often present phenomena characteristic of both solids and fluids. Sealing-wax, pitch, and ice are all brittle at low temperatures, resembling in this respect such solids as glass and stone: but they are at the very same time fluid, if time enough is allowed to exhibit the phenomenon. This is seen in the motion of glaciers, which move in every respect like true fluids, even to the middle of the stream flowing quicker than the sides, and the top than the bottom. Eddies and whirls occur in glaciers as in rivers, and also upward and downward motion, so that rocks torn off the glacier floor may be carried upward and deposited on surfaces hundreds of feet above their place of origin.—WALLACE *The Wonderful Century,* ch. 7, p. 55. (D. M. & Co., 1899.)

2929. RIVERS, TRANSPORTING POWER OF—*Earth Carried from Mountains to Sea.*—The quantity of mud held in suspension by the waters of the Ganges and Brahmaputra is found, as might be expected, to exceed that of any of the rivers alluded to in this or the preceding chapters; for, in the first place, their feeders flow from mountains of unrivaled altitude, and do not clear themselves in any lakes, as does the Rhine in the Lake of Constance, or the Rhone in that of Geneva. And, secondly, their whole course is nearer the equator than that of the Mississippi or any great river respecting which careful experiments have been made to determine the quantity of its water and earthy contents. The fall of rain, moreover, as we have before seen, is excessive on the southern flanks of the first range of mountains which

rise from the plains of Hindustan, and still more remarkable is the quantity sometimes poured down in one day. The sea, where the Ganges and Brahmaputra discharge their main stream at the flood season, only recovers its transparency at the distance of from 60 to 100 miles from the delta; and we may take for granted that the current continues to transport the finer particles much farther south than where the surface-water first becomes clear.—LYELL *Principles of Geology*, ch. 18, p. 278. (A., 1854.)

2930. RIVERS USE ROCK-DÉBRIS TO CUT DOWN OTHER ROCKS—Rivers are much more than mere transporters of sediment. Just as in desert lands wind employs disintegrated rock material as a sand-blast, so rivers use their stones, grit, and sand as tools with which to rasp, file, and undermine the rocks over which they flow. In this way their channels are gradually deepened and widened.—GEIKIE *Earth Sculpture*, ch. 2, p. 34. (G. P. P., 1898.)

2931. ROBBER-BARON OF THE AIR—*Eagle and Fish-hawk.*—What an inspiring sight it is to see one [an osprey, or fish-hawk] plunge from the air upon its prey! One can sometimes hear the splash half a mile or more, and the bird is quite concealed by the spray. It is a magnificent performance, and when, after shaking the water from his plumage, he rises into the air, I am always tempted to applaud.

The osprey, or fish-hawk, as he is also called, adheres closely to a finny diet; neither flesh nor fowl appears on his menu, and he is consequently a migratory bird, coming in April when the ice is melted, and remaining until October. In favorable localities he nests in colonies, returning year after year to the same nest.

One master, it is true, the osprey has, tho he makes a most unwilling servant. The bald-headed eagle is often an appreciative observer of the osprey's piscatorial powers, which so far exceed his own that he wisely, if unjustly, profits by them. Pursuing the osprey, he forces him to mount higher and higher until the poor bird in despair drops his prize, which the eagle captures as it falls.—CHAPMAN *Bird-Life*, ch. 7, p. 122. (A., 1900.)

2932. ——— ——— *Swiftness and Dexterity of the White-headed Eagle.*—The white-headed eagle has also developed the plundering instinct in great perfection, as is shown by the following graphic account of Audubon: "During spring and summer the white-headed eagle, to procure sustenance, follows a different course, and one much less suited to a bird apparently so well able to supply itself without interfering with other plunderers. No sooner does the first hawk make its appearance along the Atlantic shore or around the numerous and large rivers, than the eagle follows it, and, like a selfish oppressor, robs it of the hard-earned fruits of its labor. Perched on some tall summit, in view of the ocean or of some watercourse, he watches every motion of the osprey while on the wing. When the latter rises from the water, with a fish in its grasp, forth rushes the eagle in pursuit. He mounts above the fish-hawk, and threatens it by actions well understood; when the latter, fearing perhaps that its life is in danger, drops its prey. In an instant the eagle, accurately estimating the rapid descent of the fish, closes its wings, follows it with the swiftness of thought, and the next moment grasps it. The prize is carried off in silence to the woods, and assists in feeding the ever-hungry brood of the eagle."—ROMANES *Animal Intelligence*, ch. 10, p. 284. (A., 1899.)

2933. ROCK A SURE FOUNDATION—*Earthquake Resisted by.*—It would seem the harder rocks form better foundations than the softer ones. One explanation of this appears to lie in the fact that soft strata may be in a state of unstable equilibrium, and, by shaking, it is caused to settle. Another explanation is that in hard ground or rock, altho the motion is more rapid than on soft ground, this is more than compensated for by the smallness of the range of motion in the former foundation.—MILNE *Earthquake*, ch. 7, p. 131. (A., 1899.)

2934. ROCKS ROUNDED BY WAVES OF ANCIENT SEA—We raised another block in a different part of the quarry, and found that the area of a circular depression in the stratum below was broken and flawed in every direction, as if it had been the bottom of a pool recently dried up, which had shrunk and split in the hardening. Several large stones came rolling down from the diluvium in the course of the afternoon. They were of different qualities from the sandstone below and from one another; and, what was more wonderful still, they were all rounded and water-worn, as if they had been tossed about in the sea, or the bed of a river, for hundreds of years. There could not, surely, be a more conclusive proof that the bank which had enclosed them so long could not have been created on the rock on which it rested. No workman ever manufactures a half-worn article, and the stones were all half-worn! And if not the bank, why then the sandstone underneath?—MILLER *The Old Red Sandstone*, ch. 1, p. 7. (G. & L., 1851.)

2935. ROCKS, THICKNESS OF, ON OCEAN FLOOR — *Check of Radiant Heat Causes Outburst of Volcano—Repression Prepares for Outbreak.*—If the reader has any difficulty in conceiving the effects of overlaid beds in bringing about a high temperature in strata, he may help himself by a homely comparison. Let him imagine a vessel containing hot water exposed to the

cold and covered with felt or other non-conducting material; the surface of this covering will have a certain temperature. If now this vessel be covered with another thickness of felt, the temperature of the original surface will rise, and a certain gain of its heat will be made by each additional coating of non-conductive material.

The only serious question is as to the thickness of the rocks which have been laid down on the sea-floors. Hardly any geologist will doubt that it is entirely within bounds to assume that thickness much to exceed twenty miles.—SHALER *Aspects of the Earth*, p. 82. (S., 1900.)

2936. ROENTGEN RAYS DEFY REFLECTION OR REFRACTION—*A Force Not To Be Diverted.*—An exceptional property of these rays is that they cannot be either refracted or reflected as can ordinary light and heat. Hence it is only the shadow that can be photographed. And another curious result of this is that they can pass through a powder as easily as through a solid; whereas ordinary light cannot pass through powdered glass or ice, owing to the innumerable reflections and refractions which soon absorb all the rays except those reflected from a very thin surface layer. Proportionate thicknesses of aluminum or zinc, whether in the solid plate or in powder, are equally transparent to these singular rays.—WALLACE *The Wonderful Century*, ch. 5, p. 41. (D. M. & Co., 1899.)

2937. ROMANCE OF ZOOLOGY—*Slaveholding Ants.*—Some species of ants keep slaves—for instance, the reddish ant found in the meadows of Switzerland and Alsace *(Polyergus rufescens).* It is not a large, but a strong species, which has adopted the habit of sallying forth in troops from time to time to make raids upon and plunder the nests of some weaker species, such as the common *Formica fusca*. The object is, however, not to destroy or devour the ants they attack, but merely to carry off the pupæ to their own nest, where they receive every care; the workers hatched from them are then employed as servants, or, to use the usual term, as slaves. These slaves fulfil all the duties of the nest, which would otherwise have fallen to the share of the red workers; they feed the larvæ, build galleries and chambers, bring in food-supplies, and even feed their lazy masters! This is no fable, as was once thought, but an ascertained fact, proved to be such early in this century by Huber of Geneva; a celebrated observer of ants, and since fully confirmed by his pupil and successor, Auguste Forel, as well as by Sir John Lubbock. I have also convinced myself of the truth of the assertion.—WEISMANN *Heredity*, vol. ii, ch. 9, p. 25. (Cl. P., 1897.)

2938. ROOTS MAKING THEIR WAY IN THE SOIL—*Tip of Radicle a Wonderful Structure—Final Purpose of Its Various Movements.*—We believe that there is no structure in plants more wonderful, as far as its functions are concerned, than the tip of the radicle. If the tip be lightly pressed or burnt or cut it transmits an influence to the upper adjoining part, causing it to bend away from the affected side; and, what is more surprising, the tip can distinguish between a slightly harder and softer object, by which it is simultaneously pressed on opposite sides. If, however, the radicle is pressed by a similar object a little above the tip, the pressed part does not transmit any influence to the more distant parts, but bends abruptly towards the object. If the tip perceives the air to be moister on one side than on the other, it likewise transmits an influence to the upper adjoining part, which bends towards the source of moisture. When the tip is excited by light (tho in the case of radicles this was ascertained in only a single instance) the adjoining part bends from the light, but when excited by gravitation the same part bends towards the center of gravity. In almost every case we can clearly perceive the final purpose or advantage of the several movements. Two, or perhaps more, of the exciting causes often act simultaneously on the tip, and one conquers the other, no doubt, in accordance with its importance for the life of the plant. The course pursued by the radicle in penetrating the ground must be determined by the tip, hence it has acquired such diverse kinds of sensitiveness. It is hardly an exaggeration to say that the tip of the radicle thus endowed, and having the power of directing the movements of the adjoining parts, acts like the brain of one of the lower animals, the brain being seated within the anterior end of the body, receiving impressions from the sense-organs, and directing the several movements.—DARWIN *Power of Movement in Plants*, ch. 12, p. 576. (A., 1900.)

2939. ROYALTY AMONG BEES—*The Queen Feared, yet Restrained.*—The victorious queen now presented a very singular spectacle. She approached a royal cell and took this moment for uttering the sound and assuming that posture which strikes the bees motionless. For some minutes it seemed as if she would profit by the dread exhibited by the workers on guard, open the cell and destroy the young female. She also prepared to mount the cell, but in doing that she ceased to make the sound, and quitted the attitude that paralyzes the bees. Then, instantly, the guardians of the cell took courage, and by means of tormenting and biting the queen, caused her to retreat. —HUBER *Nouvelles Observations sur les Abeilles*, p. 117. (Translated for *Scientific Side-Lights.)*

2940. SACRIFICE OF GEM TO SCIENCE—*Burning of a Diamond in Oxygen.*—Faraday thus describes the burning of a diamond in oxygen by the concentrated rays of

the sun. It was effected at Florence, in presence of Sir Humphry Davy, on Tuesday, the 27th of March, 1814: "To-day we made the grand experiment of burning the diamond, and certainly the phenomena presented were extremely beautiful and interesting. A glass globe containing about 22 cubical inches was exhausted of air, and filled with pure oxygen. The diamond was supported in the center of this globe. The Duke's burning-glass was the instrument used to apply heat to the diamond. It consists of two double convex lenses, distant from each other about 3½ feet; the large lens is about 14 or 15 inches in diameter, the smaller one about 3 inches in diameter. By means of the second lens the focus is very much reduced, and the heat, when the sun shines brightly, rendered very intense. The diamond was placed in the focus and anxiously watched. On a sudden Sir H. Davy observed the diamond to burn visibly, and when removed from the focus it was found to be in a state of active and rapid combustion."—TYNDALL *Lectures on Light*, lect. 5, p. 172. (A., 1898.)

2941. SACRIFICE OF LESS FOR GREATER—*Of Present for Future, Personal for Social, Material for Spiritual.*—Men have arranged the various selves which they may seek in an hierarchical scale according to their worth. A certain amount of bodily selfishness is required as a basis for all the other selves. But too much sensuality is despised, or at best condoned on account of the other qualities of the individual. The wider material selves are regarded as higher than the immediate body. He is esteemed a poor creature who is unable to forego a little meat and drink and warmth and sleep for the sake of getting on in the world. The social self as a whole, again, ranks higher than the material self as a whole. We must care more for our honor, our friends, our human ties, than for a sound skin or wealth. And the spiritual self is so supremely precious that, rather than lose it, a man ought to be willing to give up friends, and good fame, and property, and life itself.

In each kind of self, material, social, and spiritual, men distinguish between the immediate and actual, and the remote and potential, between the narrower and the wider view, to the detriment of the former and advantage of the latter. One must forego a present bodily enjoyment for the sake of one's general health; one must abandon the dollar in the hand for the sake of the hundred dollars to come; one must make an enemy of his present interlocutor if thereby one makes friends of a more valued circle; one must go without learning, and grace, and wit, the better to compass one's soul's salvation.—JAMES *Psychology*, vol. i, ch. 10, p. 314. (H. H. & Co., 1899.)

2942. SACRIFICE OF LOWER ORGANISM FOR HIGHER—*Inoculation of Animals to Protect Man.*—It may be necessary to observe the action of supposed pathogenic organisms upon animals. This is obviously a last resource, and any abuse of such a process is strictly limited by law. As a matter of fact, an immense amount of bacteriological investigation can be carried on without inoculating animals; but, strictly speaking, as regards many of the pathogenic bacteria this test is the most reliable of all. Nor would any responsible bacteriologist be justified in certifying a water as healthy for consumption by a large community if he was in doubt as to the disease-producing action of certain contained organisms.—NEWMAN *Bacteria*, ch. 2, p. 46. (G. P. P., 1899.)

2943. SACRIFICES TO MALEVOLENCE—*Terror the Inspiration to Worship of Serpents.*—The worship of serpents has been attributed to conceptions of a very abstract character—with the circle, for example, into which they coil themselves considered as an emblem of eternity. But this is a conception far too transcendental and far-fetched to account either for the origin of this worship or for its wide extension in the world. Serpents are not the only natural objects which present circular forms. . . . They have been chosen, beyond any reasonable doubt, because of the horror and terror they inspire. For this, above all other creatures, they are prominent in Nature. For their deceptive coloring, for their insidious approach, for their deadly virus, they have been taken as the type of spiritual poison in the Jewish narrative of the Fall. The power of inflicting almost immediate death, which is possessed by the most venomous snakes, and that not by violence, but by the infliction of a wound which in itself may be hardly visible, is a power which is indeed full of mystery even to the most cultivated scientific mind, and may well have inspired among men in early ages a desire to pacify the powers of evil. The moment this becomes the great aim and end of worship a principle is established which is fertile in the development of every foul imagination. Whenever it is the absorbing motive and desire of men to do that which may most gratify or pacify malevolence, then it ceases to be at all wonderful that men should be driven by their religion to sacrifices the most horrid, and to practises the most unnatural.—ARGYLL *Unity of Nature*, ch. 12, p. 290. (Burt.)

2944. SAGACITY, ANIMAL—*Mule Drinking from Cactus.*—The mule, more cautious and cunning, adopts another method of allaying his thirst [on the plains of South America]. There is a globular and articulated plant, the *Melocactus*, which encloses under its prickly integument an aqueous pulp. After carefully striking away the prickles with his forefeet the mule cautiously ventures to apply his lips to imbibe the cooling thistle juice. But the draft from this living vegetable spring is not always

unattended by danger, and these animals are often observed to have been lamed by the puncture of the cactus thorn.—HUMBOLDT *Views of Nature*, p. 15. (Bell, 1896.)

2945. SAGACITY OF A WASP—*Cutting Bulky Prey into Manageable Parcels.*—Dr. Erasmus Darwin records an observation ("Zoonomia," i, p. 183) which, from having since been so widely quoted, deserves to be called classical. He saw a wasp upon the ground endeavoring to remove a large fly which was too heavy for it to carry off. The wasp cut off the head and abdomen, and flew away with the thorax alone. The wind, however, catching the wings of this portion made it still too unwieldy for the wasp to guide. It therefore again alighted and nipped off first one wing and then the other, when it was able to fly off with its booty without further difficulty. This observation has since been amply confirmed.—ROMANES *Animal Intelligence*, ch. 4, p. 195. (A., 1899.)

2946. SAGACITY OF ESKIMO DOGS—*The Pack Scattering When on Thin Ice, to Distribute Their Weight.*—It will be remembered in connection with these dogs that Mr. Darwin in the "Descent of Man" (p. 75) quotes Dr. Hayes, who, in his work on "The Open Polar Sea," "repeatedly remarks that his dogs, instead of continuing to draw the sledges in a compact body, diverged and separated when they came to thin ice, so that their weight might be more evenly [and widely] distributed. This was often the first warning which the travelers received that the ice was becoming thin and dangerous." Mr. Darwin remarks: "This instinct may possibly have arisen since the time, long ago, when dogs were first employed by the natives in drawing their sledges; or the Arctic wolves, the parent stock of the Eskimo dog, may have acquired an instinct impelling them not to attack their prey in a close pack when on thin ice."—ROMANES *Animal Intelligence*, ch. 16, p. 462. (A., 1899.)

2947. SAGACITY SURPASSES THEORY—*Regelation of Ice and Snow.*—Two fragments of ordinary table ice brought carefully together freeze and cement themselves at their place of junction: or if two pieces floating in water be brought together, they instantly freeze, and by laying hold of either of them gently you can drag the other after it through the water. Imagine such points of attachment distributed in great numbers through a mass of snow. The substance becomes thereby a semisolid instead of a mass of powder. My guide, however, unaided by any theory, did a thing from which I should have shrunk, tho backed by all the theories in the world [viz., tramping Alpine snow into a firm support].—TYNDALL *Hours of Exercise in the Alps*, ch. 9, p. 100. (A., 1898.)

2948. SALT A NECESSITY OF LIFE—Common salt . . . is an article of food, tho often miscalled a condiment. Salt is food simply because it supplies the blood with one of its normal and necessary constituents, chlorid of sodium, without which we cannot live. A certain quantity of it exists in most of our ordinary food, but not always sufficient.—WILLIAMS *Chemistry of Cookery*, ch. 15, p. 259. (A., 1900.)

2949. SALVATION AN ACTIVE, EFFECTIVE PRINCIPLE—*The Definitive Overcoming of the Law of Deterioration and Death.*—There is a natural principle in man, lowering him, deadening him, pulling him down by inches to the mere animal plane, blinding reason, searing conscience, paralyzing will. This is the active destroying principle, or sin. Now to counteract this God has discovered to us another principle which will stop this drifting process in the soul, steer it round, and make it drift the other way. This is the active saving principle, or salvation. To neglect it is to cut off the only possible chance of escape. In declining this he is simply abandoning himself with his eyes open to that other and terrible energy which is already there, and which, in the natural course of things, is bearing him every moment further and further from escape.—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 96. (H. Al.)

2950. SAND A PRESERVER OF ANCIENT MONUMENTS—No mode of interment can be conceived more favorable to the conservation of monuments for indefinite periods than that now so common in the region immediately westward of the Nile. The sand which surrounded and filled the great temple of Ipsambul, first discovered by Burckhardt, and afterwards partially uncovered by Belzoni and Beechey, was so fine as to resemble a fluid when put in motion. Neither the features of the colossal figures, nor the color of the stucco with which some were covered, nor the paintings on the walls, had received any injury from being enveloped for ages in this dry impalpable dust.—LYELL *Principles of Geology*, ch. 45, p. 726. (A., 1854.)

2951. SAND-BAR SHIFTED BY STORM—It sometimes happens that during a violent storm a large bar of sand is suddenly made to shift its position, so as to prevent the free influx of the tides, or efflux of river water. Thus about the year 1500 the sands at Bayonne were suddenly thrown across the mouth of the Adour. That river, flowing back upon itself, soon forced a passage to the northward along the sandy plain of Capbreton till at last it reached the sea at Boucau, at the distance of seven leagues from the point where it had formerly entered. It was not till the year 1579 that the celebrated architect Louis de Foix undertook, at the desire of Henry III., to reopen the ancient channel, which he at last

effected with great difficulty.—LYELL *Principles of Geology*, bk. ii, ch. 21, p. 338. (A., 1854.)

2952. SAVAGE COMPARED WITH BRUTE—*Reasoning Power Divides Man from Lower Animals.*—A creature which has few instinctive impulses, or interests, practical or esthetic, will dissociate few characters, and will, at best, have limited reasoning powers; whilst one whose interests are very varied will reason much better. Man, by his immensely varied instincts, practical wants, and esthetic feelings, to which every sense contributes, would, by dint of these alone, be sure to dissociate vastly more characters than any other animal; and accordingly we find that the lowest savages reason incomparably better than the highest brutes.—JAMES *Psychology*, vol. ii, ch. 22, p. 345. (H. H. & Co., 1890.)

2953. SAVAGE, HOW NATURE MOVES THE—*The Struggle for Life Develops New and Higher Powers.*—Start with a comparatively unevolved savage, and see what the struggle for life will do for him. When we meet him first he is sitting, we shall suppose, in the sun. Let us also suppose—and it requires no imagination to suppose it—that he has no wish to do anything else than sit in the sun, and that he is perfectly contented, and perfectly happy. Nature around him, visible and invisible, is as still as he is, as inert apparently, as unconcerned. Neither molests the other; they have no connection with each other. Yet it is not so. That savage is the victim of a conspiracy. Nature has designs upon him, wants to do something to him. That something is to move him. Why does it wish to move him? Because movement is work, and work is exercise, and exercise may mean a further evolution of the part of him that is exercised. How does it set about moving him? By moving itself. Everything else being in motion, it is impossible for him to resist. The sun moves away to the west and he must move or freeze with cold. As the sun continues to move, twilight falls and wild animals move from their lairs, and he must move or be eaten. The food he ate in the morning has dissolved and moved away to nourish the cells of his body, and more food must soon be moved to take its place or he must starve. So he starts up, he works, he seeks food, shelter, safety; and those movements make marks in his body, brace muscles, stimulate nerves, quicken intelligence, create habits, and he becomes more able and more willing to repeat these movements and so becomes a stronger and a higher man.—DRUMMOND *Ascent of Man*, ch. 6, p. 191. (J. P., 1900.)

2954. SAVAGE SURPASSES BRUTE—*Capacity for Language, Learning, Progress.*—In the comparison of man with other animals the standard should naturally be the lowest man, or savage. But the savage is possessed of human reason and speech, while his brain-power, tho it has not of itself raised him to civilization, enables him to receive more or less of the education which transforms him into a civilized man. To show how man may have advanced from savagery to civilization is a reasonable task. . . . But there is no such evidence available for crossing the mental gulf that divides the lowest savage from the highest ape. On the whole, the safest conclusion warranted by facts is that the mental machinery of the lower animals is roughly similar to our own, up to a limit. Beyond this limit the human mind opens out into wide ranges of thought and feeling which the beast-mind shows no sign of approaching. If we consider man's course of life from birth to death, we see that it is, so to speak, founded on functions which he has in common with lower beings. Man, endowed with instinct and capable of learning by experience, drawn by pleasure and driven by pain, must, like a beast, maintain his life by food and sleep, must save himself by flight, or fight it out with his foes, must propagate his species and care for the next generation. Upon this lower framework of animal life is raised the wondrous edifice of human language, science, art, and law.—TYLOR *Anthropology*, ch. 2, p. 54. (A., 1899.)

2955. SAVAGERY AS MODERN AS CIVILIZATION—*The Same Distance from Primeval Life.*—It is to be remembered that the savage of the present day is as far removed in time from the common origin of our race as the man who now exhibits the highest type of moral and intellectual culture. Whether that time is represented by six thousand, or ten thousand, or a hundred thousand years, it is the same for both. If, therefore, the number of years since the origin of man be taken as a multiplier in the processes of elevation, it must be taken equally as a multiplier in the processes of degradation. Not even on the theory which some hold, that the human species has spread from more than one center of birth or of creation, can this conclusion be affected. For even on this hypothesis of separate origins there is no reason whatever to suppose that the races which are now generally civilized are of more recent origin than those which are generally savage. Presumably, therefore, all the ages which have been at work in the development of civilization have been at work equally in the development of savagery. It is not possible in the case of savagery, any more than in the case of civilization, that all those ages have been without effect. Nor is it possible that the changes they have wrought have been all in one direction. The conclusion is, that neither savagery nor civilization, as we now see them, can represent the primeval condition of man. Both of them

are the work of time. Both of them are the product of evolution.—ARGYLL *Unity of Nature*, ch. 10, p. 232. (Burt.)

2956. SAVAGES AMIDST CIVILIZATION—Out of 164,000 persons committed to prison in England and Wales, only 4,000 could read and write well. In fact, our criminal population are mere savages, and most of their crimes are but injudicious and desperate attempts to live as a savage in the midst and at the expense of a civilized community.—AVEBURY *Prehistoric Times*, ch. 16, p. 574. (A., 1900.)

2957. SAVAGES DISTORT FACTS OF RECENT EVENTS—Even as regards events which are contemporary, or nearly so, we find that the accounts given by savages become rapidly distorted. Thus Nilsson quotes the account given by Mackenzie that the Eskimos described the English to him as being giants, with wings, who could kill with a glance of their eye, and swallow a whole beaver at a mouthful.—AVEBURY *Prehistoric Times*, ch. 13, p. 405. (A., 1900.)

2958. SAVAGES, DOMESTIC LIFE OF—*Oppression of Woman Not Universal.*—Cruelty does not breed refinement either of manners or of taste. Where women adorn themselves with flowers, and produce with skilful fingers work that will excite the admiration of the most refined, their home can hardly be the abode of cruelty. Of one of the most primitive peoples E. H. Man says: "It is incorrect to say that among the Andamanese marriage is nothing more than taking a female slave, for one of the striking features of their social relation is the marked equality and affection which subsists between husband and wife. Careful observations extended over many years prove that not only is the husband's authority more or less nominal, but that it is not at all an uncommon occurrence for Andamanese benedicts to be considerably at the beck and call of their better halves."—MASON *Woman's Share in Primitive Culture*, int., p. 7. (A., 1894.)

2959. SCAFFOLDING OF SCIENCE—*Dry Bones of Detail—Astronomy in Itself Interesting and Practical.*—Far from being a difficult and inaccessible science, astronomy is the science which concerns us most, the one most necessary for our general instruction, and at the same time the one which offers for our study the greatest charms and keeps in reserve the highest enjoyments. We cannot be indifferent to it, for it alone teaches us where we are and what we are; and, moreover, it need not bristle with figures, as some severe savants would wish us to believe. The algebraical formulæ are merely scaffoldings analogous to those which are used to construct an admirably designed palace. The figures drop off, and the palace of Urania shines in the azure, displaying to our wondering eyes all its grandeur and all its magnificence.—FLAMMARION *Popular Astronomy*, bk. i, ch. 1, p. 1. (A.)

2960. SCALES USED BY PRIMITIVE MAN—The scale or balance was known in America before the discovery. The Peruvians made beams of bone, suspended little nets to each end, supported the beam at the middle by means of a cord, and used stones for weights. The transition from the balance to the "steelyard" is not easy to make out.—MASON *Origins of Invention*, ch. 2, p. 68. (S., 1899.)

2961. SCAVENGERS, INSECTS AS—*The "Driver Ants" Help to Purify Tropical Lands—Invasion of Human Dwellings.*—Savage . . . has given a graphic account of the driver ants *(Anomma arcens)* of West Africa. They keep down, he says, "the more rapid increase of noxious insects and smaller reptiles; consume much dead animal matter, which is constantly occurring, decaying, becoming offensive, and thus vitiating the atmosphere, and which is by no means the least important in the torrid zone, often compelling the inhabitants to keep their dwellings, towns, and their vicinity in a state of comparative cleanliness. The dread of them is upon every living thing. . . .

"Their entrance into a house is soon known by the simultaneous and universal movement of rats, mice, lizards, *Blapsidæ*, *Blattidæ*, and of the numerous vermin that infest our dwellings. . . .

"They move over the house with a good degree of order, unless disturbed, occasionally spreading abroad, ransacking one point after another, till, either having found something desirable, they collect upon it, when they may be destroyed *en masse* by hot water. . . .

"When they are fairly in, we give up the house, and try to await with patience their pleasure, thankful, indeed, if permitted to remain within the narrow limits of our beds or chairs."

These ants will soon destroy even the largest animal if it is confined. In one case Savage saw them kill near his house a snake four feet long.—AVEBURY *Ants, Bees, and Wasps*, ch. 4, p. 63. (A., 1900.)

2962. SCAVENGERS OF THE SEA—*Service Rendered by Gulls—Ocean Transformed by Their Life and Beauty.*—The herring gull . . . is the gull we see in such numbers in our bays and harbors, flying gracefully and apparently aimlessly about, but in reality ever keeping its bright black eyes fixed on the water in search of some floating morsel, which it deftly picks from the surface. It frequently follows vessels, hanging over the stern day after day, and deserting its post only to feed on scraps thrown overboard from the galley. . . . Gulls do excellent service in devouring much refuse that would otherwise be cast ashore to decay; but, useful as they are as scaven-

gers, I feel that their place in Nature is to animate the barren wastes of the sea. How, when at sea, the presence of a single gull changes the whole aspect of Nature! The great expanse of water, which before was oppressive in its dreary lifelessness, is transformed by the white-winged gulls into a scene of rare beauty. Every voyager, be he naturalist or not, admires their grace of form and motion. They seem born of the waves, and as much a part of the ocean as the foamy whitecaps themselves.—CHAPMAN *Bird-Life*, ch. 7, p. 88. (A., 1900.)

2963. SCIENCE ACCEPTS POPULAR BELIEF—*Rhea's Stomach an Ancient Remedy—Now Valued for Pepsin.*—More than two centuries ago (very ancient times for South America) the gauchos were accustomed to take the lining of the rhea's stomach, dried and powdered, for ailments caused by impaired digestion, and the remedy is popular still. Science has gone over to them, and the ostrich-hunter now makes a double profit, one from the feathers, and the other from the dried stomachs which he supplies to the chemists of Buenos Ayres. Yet he was formerly told that to take the stomach of the ostrich to improve his digestion was as wild an idea as it would be to swallow birds' feathers in order to fly.—HUDSON *Naturalist in La Plata*, ch. 4, p. 79. (C. & H., 1895.)

2964. SCIENCE ADDS GLORY TO THE VISION OF REDEMPTION—I do not enter at all into the positive evidence for the truth of the Christian revelation, my single aim at present being to dispose of one of the objections which is conceived to stand in the way of it. Let me suppose, then, that this is done to the satisfaction of a philosophical inquirer, and that the evidence is sustained; and that the same mind that is familiarized to all the sublimities of natural science, and has been in the habit of contemplating God in association with all the magnificence which is around him, shall be brought to submit its thoughts to the captivity of the doctrine of Christ. Oh! with what veneration, and gratitude, and wonder should he look on the descent of Him into this lower world who made all these things, and without whom was not anything made that was made. What a grandeur does it throw over every step in the redemption of a fallen world, to think of its being done by Him who unrobed him of the glories of so wide a monarchy, and came to this humblest of its provinces, in the disguise of a servant, and took upon him the form of our degraded species, and let himself down to sorrows, and to sufferings, and to death, for us! In this love of an expiring Savior to those for whom in agony he poured out his soul there is a height, and a depth, and a length, and a breadth, more than I can comprehend; and let me never from this moment neglect so great a salvation, or lose my hold of an atonement, made sure by Him who cried that it was finished, and brought in an everlasting righteousness.—CHALMERS *Astronomical Discourses*, disc. 3, p. 85. (R. Ct., 1848.)

2965. SCIENCE ADVANCED BY ARABS IN SPITE OF HINDRANCES—Alchemy, magic, and mystic fancies, deprived by scholastic phraseology of all poetic charm, corrupted here, as elsewhere, in the Middle Ages, the true results of inquiry; but still the Arabs have enlarged the views of Nature, and given origin to many new elements of knowledge, by their indefatigable and independent labors, while, by means of careful translations into their own tongue, they have appropriated to themselves the fruits of the labors of earlier cultivated generations. Attention has been justly drawn to the great difference existing in the relations of civilization between immigrating Germanic and Arabian races. The former became cultivated after their immigration; the latter brought with them from their native country not only their religion, but a highly polished language, and the graceful blossoms of a poetry which has not been wholly devoid of influence on the Provençals and Minnesingers.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 212. (H., 1897.)

2966. SCIENCE, A HIGHER, NOT TO BE MERGED IN A LOWER—*Chemistry—Mechanics—Physiology—Terms of the Lower Misrepresent the Higher.*—"Any attempt to merge the distinctive characteristic of a higher science in a lower—of chemical changes in mechanical; of physiological in chemical; above all, of mental changes in physiological—is a neglect of the radical assumption of all science, because it is an attempt to deduce representations—or rather misrepresentations—of one kind of phenomenon from a conception of another kind which does not contain it, and must have it implicitly and illicitly smuggled in before it can be extracted out of it. Hence, instead of increasing our means of representing the universe to ourselves without the detailed examination of particulars, such a procedure leads to misconstructions of fact on the basis of an imported theory, and generally ends in forcibly perverting the least known science to the type of the better known."—DRUMMOND *Natural Law in the Spiritual World*, int., p. 19. (H. Al.)

2967. SCIENCE A LIVING REALITY—*To Know the Actual Earth and the Starry Heavens—Carlyle's Lament.*—Think of true science as a living reality; as a faithful expounder of all that is worth knowing and that can be known; as an existing power, ever anxious in its unwearied march for the good and welfare of mankind; and best of all, perhaps, as an ever-willing instructor of all who will come to be taught. . . . Let us bend the educational twig in its early growth that our ef-

forts may be perceptible on the fully grown tree. Let us send our boys and girls out into the world, knowing something of the world, of its wonders and of themselves, as well as of the proprieties of life, or of the dead languages and modern tongues. I think Carlyle well expresses himself regarding the want of such information when he says: "For many years it has been one of my constant regrets that no schoolmaster of mine had a knowledge of natural history—so far, at least, as to have taught me the grasses that grow by the wayside, and the little winged or wingless neighbors that are continually meeting me with a salutation that I cannot answer as things are. Why," he continues, "did not somebody teach me the constellations, and make me at home in the starry heavens which are always overhead, and which I don't half know to this day?"—ANDREW WILSON *Science-Culture for the Masses*, p. 30. (A., 1888.)

2968. SCIENCE AND PHILOSOPHY—*Each Needs Help from the Other.*—If we consider and compare the most important advances which the human mind has made in the knowledge of truth, we shall soon see that it is always owing to philosophical mental operations that these advances have been made, and that the experience of the senses which certainly and necessarily precedes these operations, and the knowledge of details gained thereby, only furnish the basis for those general laws. Experience and philosophy, therefore, by no means stand in such exclusive opposition to each other as most men have hitherto supposed; they rather necessarily supplement each other. The philosopher who is wanting in the firm foundation of sensuous experience, of empirical knowledge, is very apt to arrive at false conclusions in his general speculations, which even a moderately informed naturalist can refute at once. On the other hand, the purely empiric naturalists, who do not trouble themselves about the philosophical comprehension of their sensuous experiences and who do not strive after general knowledge, can promote science only in a very slight degree, and the chief value of their hard-won knowledge of details lies in the general results which more comprehensive minds will one day derive from them.—HAECKEL *History of Creation*, vol. i, ch. 4, p. 81. (K. P. & Co., 1899.)

2969. SCIENCE AND THE SCHOOLMEN—*The Abdication of Galileo.*—The early part of the seventeenth century, when Descartes reached manhood, is one of the great epochs of the intellectual life of mankind. At that time, physical science suddenly strode into the arena of public and familiar thought, and openly challenged, not only philosophy and the church, but that common ignorance which passes by the name of common sense. The assertion of the motion of the earth was a defiance to all three, and physical science threw down her glove by the hand of Galileo. It is not pleasant to think of the immediate result of the combat; to see the champion of science, old, worn, and on his knees before the Cardinal Inquisitor, signing his name to what he knew to be a lie. . . . But two hundred years have passed, and however feeble or faulty her soldiers, physical science sits crowned and enthroned as one of the legitimate rulers of the world of thought. Charity children would be ashamed not to know that the earth moves; while the schoolmen are forgotten.—HUXLEY *Lay Sermons*, serm. 14, p. 330. (G. P. P., 1899.)

2970. SCIENCE, APPLIED—*Not a Special Branch, but Simply the Practical Use of All.*—Pasteur, one of the most eminent members of the Institute of France, in accounting for the disastrous overthrow of his country and the predominance of Germany in the late war, expresses himself thus: "Few persons comprehend the real origin of the marvels of industry and the wealth of nations. I need no further proof of this than the employment more and more frequent in official language, and in writing of all sorts, of the erroneous expression *applied science*. The abandonment of scientific careers by men capable of pursuing them with distinction was recently deplored in the presence of a minister of the greatest talent. The statesman endeavored to show that we ought not to be surprised at this result, because *in our day the reign of theoretic science yielded place to that of applied science*. Nothing could be more erroneous than this opinion, nothing, I venture to say, more dangerous, even to practical life, than the consequences which might flow from these words. They have rested in my mind as a proof of the imperious necessity of reform in our superior education. There exists no category of the sciences to which the name of 'applied' science could be rightly given. *We have science, and the applications of science*, which are united together as the tree and its fruit." [See PRACTISE.] —TYNDALL *Lectures on Light*, p. 223. (A., 1898.)

2971. SCIENCE A REST FROM STRIFE—*Man against Man.*—While on the steppe tigers and crocodiles contend with horses and cattle, so on the forest borders and in the wilds of Guiana the hand of man is ever raised against his fellow man. With revolting eagerness some tribes drink the flowing blood of their foes, whilst others, seemingly unarmed, yet prepared for murder, deal certain death with a poisoned thumb-nail. The feebler tribes, when they tread the sandy shores, carefully efface with their hands the traces of their trembling steps. Thus does man, everywhere alike, on the lowest scale of brutish debasement, and in the false glitter of his higher culture, perpetually create for himself a life of care. And thus, too, the traveler, wandering over

the wide world by sea and land, and the historian who searches the records of bygone ages, are everywhere met by the unvarying and melancholy spectacle of man opposed to man. He, therefore, who amid the discordant strife of nations, would seek intellectual repose, turns with delight to contemplate the silent life of plants, and to study the hidden forces of Nature in her sacred sanctuaries; or yielding to that inherent impulse, which for thousands of years has glowed in the breast of man, directs his mind by a mysterious presentiment of his destiny towards the celestial orbs, which, in undisturbed harmony, pursue their ancient and eternal course.—HUMBOLDT *Views of Nature*, p. 20. (Bell, 1896.)

2972. SCIENCE BEFORE INSTRUMENTS—*Discovery of Kepler's Laws Antedated the Telescope—Achievements of Tycho Brahe and Other Early Scientists.*—The basis of a very important part of the astronomy of our planetary system was already laid before the memorable years 1608 and 1610, and therefore before the great epoch of the invention of telescopic vision, and its application to astronomical purposes. The treasure transmitted by the learning of the Greeks and Arabs was augmented by the careful and persevering labors of George Purbach, Regiomontanus (*i. e.*, Johann Müller), and Bernhard Walther, of Nürnberg. To their efforts succeeded a bold and glorious development of thought—the Copernican system; this, again, was followed by the rich treasures derived from the exact observations of Tycho Brahe and the combined acumen and persevering spirit of calculation of Kepler. Two great men, Kepler and Galileo, occupy the most important turning-point in the history of measuring astronomy, both indicating the epoch that separates observation by the naked eye, tho aided by greatly improved instruments of measurement, from telescopic vision. Galileo was at that period forty-four, and Kepler thirty-seven years of age; Tycho Brahe, the most exact of the measuring astronomers of that great age, had been dead seven years. . . . None of Kepler's contemporaries, Galileo not excepted, bestowed any adequate praise on the discovery of the three laws which have immortalized his name. Discovered by purely empirical methods, altho more rich in results to the whole domain of science than the isolated discovery of unseen cosmical bodies, these laws belong entirely to the period of natural vision, to the epoch of Tycho Brahe and his observations, altho the printing of the work entitled "Astronomia nova seu Physica cœlestis de motibus Stellæ Martis" was not completed until 1609, and the third law, that the squares of the periodic times of revolution of two planets are as the cubes of their mean distances, was first fully developed in 1619.—HUMBOLDT *Cosmos*, vol. iii. p. 69. (H., 1897.)

2973. SCIENCE BROADENS OUR ESTIMATE OF THE UNIVERSE—*Leads to Modest Estimate of Ourselves (Ps. viii, 4).*—Did the discoveries of science stop here, we have enough to justify the exclamation of the psalmist, "What is man, that thou are mindful of him; or the son of man, that thou shouldest deign to visit him?" They widen the empire of creation far beyond the limits which were formerly assigned to it. They give us to see that yon sun, throned in the center of his planetary system, gives light, and warmth, and the vicissitude of seasons to an extent of surface several hundreds of times greater than that of the earth which we inhabit. They lay open to us a number of worlds, rolling in their respective circles around this vast luminary, and prove that the ball which we tread upon, with all its mighty burden of oceans and continents, instead of being distinguished from the others, is among the least of them, and, from some of the more distant planets, would not occupy a visible point in the concave of their firmament. They let us know that tho this mighty earth, with all its myriads of people, were to sink into annihilation, there are some worlds where an event so awful to us would be unnoticed and unknown, and others where it would be nothing more than the disappearance of a little star which had ceased from its twinkling. We should feel a sentiment of modesty at this just but humiliating representation. We should learn not to look on our earth as the universe of God, but one paltry and insignificant portion of it; that it is only one of the many mansions which the Supreme Being has created for the accommodation of his worshipers, and only one of the many worlds rolling in that flood of light which the sun pours around him to the outer limits of the planetary system.—CHALMERS *Astronomical Discourses*, p. 24. (R. Ct., 1848.)

2974. SCIENCE CANNOT DISPROVE THEOLOGY—*Redemption May Reach All the Worlds of Space.*—For anything he [the objector] can tell, sin has found its way into these other worlds. For anything he can tell, their people have banished themselves from communion with God. . . . For anything he can tell, the redemption proclaimed to us is not one solitary instance, or not the whole of that redemption which is by the Son of God, but only our part in a plan of mercy, equal in magnificence to all that astronomy has brought within the range of human contemplation. For anything he can tell, the moral pestilence, which walks abroad over the face of our world, may have spread its desolations over all the planets of all the systems which the telescope has made known to us. . . . For anything he can tell, the wonder-working God, who has strewed the field of immensity with so many worlds, and spread the shelter of his omnipotence over them, may have sent a message of love to each. . . . For anything

he can tell, angels from paradise may have sped to every planet their delegated way, and sung from each azure canopy a joyful annunciation, and said, "Peace be to this residence, and good-will to all its families, and glory to him in the highest, who, from the eminency of his throne, has issued an act of grace so magnificent as to carry the tidings of life and of acceptance to the unnumbered orbs of a sinful creation."—CHALMERS *Astronomical Discourses*, p. 58. (R. Ct., 1848.)

2975. SCIENCE CANNOT PROVE IMMORTALITY—*Types of Sound and Flame.*—As yet we know of no fact, which can be established by scientific observation, which would show that the finer and complex forms of vital motion could exist otherwise than in the dense material of organic life; that it can propagate itself as the sound-movement of a string can leave its originally narrow and fixed home and diffuse itself in the air, keeping all the time its pitch and the most delicate shade of its color-tint; and that, when it meets another string attuned to it, starts this again or excites a flame ready to sing to the same tone. The flame, even, which, of all processes in inanimate Nature, is the closest type of life, may become extinct, but the heat which it produces continues to exist—indestructible, imperishable, as an invisible motion, now agitating the molecules of ponderable matter, and then radiating into boundless space as the vibration of an ether. Even there it retains the characteristic peculiarities of its origin, and it reveals its history to the inquirer who questions it by the spectroscope. United afresh, these rays may ignite a new flame, and thus, as it were, acquire a new bodily existence.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 194. (L. G. & Co., 1898.)

2976. SCIENCE CONFRONTED WITH MYSTERY—*Transition from Phenomena of Physics to Phenomena of Thought across a Gulf.*—When we endeavor to pass by a similar process from the phenomena of physics to those of thought we meet a problem which transcends any conceivable expansion of the powers which we now possess. We may think over the subject again and again, but it eludes all intellectual presentation. We stand at length face to face with the incomprehensible. The territory of physics is wide, but it has its limits from which we look with vacant gaze into the region beyond. Let us follow matter to its utmost bounds, let us claim it in all its forms—even in the muscles, blood, and brain of man himself—as ours to experiment with and to speculate upon. Casting the term "vital force" from our vocabulary, let us reduce, if we can, the visible phenomena of life to mechanical attractions and repulsions. Having thus exhausted physics and reached its very rim, a mighty mystery still looms beyond us. We have, in fact, made no step towards its solution.—TYNDALL *Fragments of Science*, vol. ii, ch. 15, p. 391. (A., 1900.)

2977. SCIENCE, CONQUESTS OF—*Arabs Not Fitted to Work Out Highest Results.*—As Wilhelm von Humboldt observes: "What would be the condition of our civilization at the present day if the Arabs had remained, as they long did, the sole possessors of scientific knowledge, and had spread themselves permanently over the west? A less favorable result would probably have supervened. . . . It is to the same causes which procured for the Romans a dominion over the world—the Roman spirit and character—and not to external and merely adventitious chances, that we owe the influence exercised by the Romans on our civil institutions, our laws, languages, and culture. It was owing to this beneficial influence and to the intimate alliance of races that we were rendered susceptible to the influence of the Greek mind and language, while the Arabs directed their consideration principally only to those scientific results of Greek investigation which referred to the description of Nature, and to physical, astronomical, and purely mathematical science." The Arabs, by carefully preserving the purity of their native tongue, and the delicacy of their figurative modes of expression, were enabled to impart the charm of poetic coloring to the expression of feeling and of the noble axioms of wisdom; but, to judge from what they were under the Abbassides, had they built on the same foundation with which we find them familiar it is scarcely probable that they could have produced those works of exalted poetic and creative art which, fused together in one harmonious accord, are the glorious fruits of the mature season of our European culture.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 227. (H., 1897.)

2978. SCIENCE DEMANDS A LIFE BEYOND THAT OF THE SENSES—*Pictorial Power Needed to Deal with Underlying Principles.*—The life of the experimental philosopher is twofold. He lives, in his vocation, a life of the senses, using his hands, eyes, and ears in his experiments; but such a question as that now before us [the ultimate nature of light] carries him beyond the margin of the senses. He cannot consider, much less answer, the question, "What is light?" without transporting himself to a world which underlies the sensible one, and out of which spring all optical phenomena. To realize this subsensible world, if I may use the term, the mind must possess a certain pictorial power.—TYNDALL *Lectures on Light*, lect. 2, p. 43. (A., 1898.)

2979. SCIENCE DEPENDENT ON ENVIRONMENT—Indeed, the experience acquired by its [the telescope of Lord Rosse] use plainly shows that atmospheric rather than mechanical difficulties impede a still further increase of telescopic power. Its

construction may accordingly be said to mark the *ne plus ultra* of effort in one direction, and the beginning of its conversion towards another. It became thenceforward more and more obvious that the conditions of observation must be ameliorated before any added efficacy could be given to it. The full effect of an uncertain climate in nullifying optical improvements was recognized, and the attention of astronomers began to be turned toward the advantages offered by more tranquil and more translucent skies.—CLERKE *History of Astronomy*, pt. i, ch. 6, p. 148. (Bl., 1893.)

2980. SCIENCE DESTROYING IDOLATRY—*Sun-worship Impossible—Mind Alone Adorable.*—Has not science, for example, even in these last few years, rendered forever impossible one of the oldest and most natural of the idolatries of the world? It has disclosed to us the physical constitution of the sun—that great heavenly body which is one of the chief proximate causes of all that we see and enjoy on earth, and which has seemed most naturally the very image of the Godhead to millions of the human race. We now know the sun to be simply a very large globe of solid and of gaseous matter, in a state of fierce and flaming incandescence. No man can worship a ball of fire, however big, nor can he feel grateful to it, nor love it, nor adore it, even tho its beams be to him the very light of life. Neither in it nor in the mere physical forces of which it is the center can we see anything approaching to the rank and dignity of even the humblest human heart. "What know we greater than the soul?" It is only when we come to think of the coordination and adjustment of these physical forces as part of the mechanism of the heavens—it is only, in short, when we recognize the mental . . . element, that the universe becomes glorious and intelligible, as indeed a cosmos—a system of order and beauty adapted to the various ends which we see actually attained, and to a thousand others which we can only guess.—ARGYLL *Unity of Nature*, ch. 8, p. 183. (Burt.)

2981. SCIENCE DOES NOT CONTROL ACTIVITIES—*Logic and Reasoning—Ethics and Conduct.*—The science of logic never made a man reason rightly, and the science of ethics (if there be such a thing) never made a man behave rightly. The most such sciences can do is to help us to catch ourselves up and check ourselves, if we start to reason or to behave wrongly, and to criticize ourselves more articulately after we have made mistakes. A science only lays down lines within which the rules of the art must fall, laws which the follower of the art must not transgress; but what particular thing he shall positively do within those lines is left exclusively to his own genius.—JAMES *Talks to Teachers*, ch. 1, p. 8. (H. H. & Co., 1900.)

2982. SCIENCE DOES NOT DISDAIN THE KITCHEN—*Meat Cooked at Lower Temperature.*—At Munich water boils at 209½° (on account of its elevation), while in London the boiling-point is 212°. "Yet nobody, I believe, ever perceived that boiled meat was less done at Munich than at London. But if meat may without the least difficulty be cooked with a heat of 209½° at Munich, why should it not be possible to cook it with the same degree of heat in London? If this can be done in London (which, I think, can hardly admit of a doubt), then it is evident that the process of cookery which is called boiling may be performed in water which is not boiling hot."—COUNT RUMFORD, quoted by WILLIAMS in *Chemistry of Cookery*, ch. 2, p. 16. (A. 1900.)

2983. SCIENCE, ECONOMIC VALUE OF—*Pasteur Saves Silk Culture of France.*—If also you will read the account . . . of Pasteur's researches into the nature and cause of the great silkworm disease, known as "pebrine," which decimates that insect species as cholera slays its human thousands, you will discover how a zoological study saved the commercial prosperity of France. Prior to Pasteur's researches the silkworms died in multitudes from the mysterious epidemic, and blank ruin stared the silk-growers and -cultivators in the face. When, however, by careful study of the causes and conditions of the disease, Pasteur had made himself master of the situation, and had found that a minute plant-organism, propagating itself within the bodies of the silkworms and readily conveyed from one to the other, was the cause of the disorder, his countrymen fully realized the truth of the proverb that "knowledge is power," and that to scientific research was due the salvation of their commerce and the rescue of their happiness and prosperity.—ANDREW WILSON *Science-Culture for the Masses*, p. 32. (Hum., 1888.)

2984. SCIENCE FAVORS SIMPLICITY—*Plain Language Required by Royal Society.*— It [the Royal Society in time of Charles II.] "exacted from all its members a close, naked, natural way of speaking, positive expressions, clear senses, a native easiness, bringing all things as near the mathematical plainness as they can, and preferring the language of artisans, countrymen, and merchants before that of wits or scholars." Thence sprang that requirement which enters into all highly developed modern systems of patent law, that a specification shall not be addressed to the erudite and learned, but shall be written in such full, clear, and exact terms that any person skilled in the art to which it nearest relates shall be able to understand it and put it in practise. In a word, the Royal Society completely revolutionized didactic and technical writing and the mode of expressing scientific thought, and thereby did enough, had it immediately afterwards gone out of

existence, to earn for itself the perpetual gratitude of mankind.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 13, p. 412. (J. W., 1898.)

2985. SCIENCE FOUNDED ON FAITH—*Confidence in the Order of Nature—Man's Thought Sweeps All Space and All Time.*—It may perhaps appear rash that we —restricted as we are in the circle of our observations in space, by our position on this little earth, which is but as a grain of dust in our Milky Way, and limited in time by the short duration of the human race—that we should attempt to apply the laws which we have deduced from the confined circle of facts open to us to the whole range of infinite space, and of time from everlasting to everlasting. But all our thought and our action, in the greatest as well as in the least, is based on our confidence in the unchangeable order of Nature, and this confidence has hitherto been the more justified the deeper we have penetrated into the interconnections of natural phenomena. And that the general laws, which we have found, also hold for the most distant vistas of space, has acquired strong actual confirmation during the past half-century. — HELMHOLTZ *Popular Lectures*, lect. 4, p. 144. (L. G. & Co., 1898.)

2986. SCIENCE, FOUR PILLARS OF—*Nothing Proved Till "Foursquare to Opposition"—Crude and Hasty Inference Rebuked.*—Every completed scientific investigation must consist of four series of operations. In the first of these an attempt is made to collect the whole of the facts bearing on the question, by means of observation and experiment, the latter being only observation under conditions determined by ourselves. In the second stage of the inquiry the attention is directed to classifying and grouping the isolated facts, so as to determine their bearings upon one another and the general conclusions to which they appear to point. In the third stage it is sought to frame an hypothesis which shall embrace all the observed facts, and shall be in harmony with the general conclusions derived from them. In the fourth stage this hypothesis is put to the most rigid test, comparing the results which must follow, if it be true, with the phenomena actually observed, and rejecting or amending our hypothesis accordingly. Every great scientific theory has thus been established by these four processes—observation, generalization, hypothesis, and verification.—JUDD *Volcanoes*, ch. 12, p. 331. (A., 1899.)

2987. SCIENCE HAS ALWAYS NEW WORLDS TO CONQUER—As men contemplate the riches of Nature, and see the mass of observations incessantly increasing before them, they become impressed with the intimate conviction that the surface and the interior of the earth, the depths of the ocean, and the regions of air will still, when thousands and thousands of years have passed away, open to the scientific observer untrodden paths of discovery. The regret of Alexander cannot be applied to the progress of observation and intelligence.—HUMBOLDT *Cosmos*, vol. i, int., p. 41. (H., 1897.)

2988. SCIENCE INDEPENDENT OF PHILOSOPHICAL THEORIES—*Investigator Should Keep to His Own Department.*—Neither materialism nor spiritualism is a scientific term, and one need have no concern with them in a scientific inquiry which, if it be true to its spirit, is bound to have regard only to what lies within its powers and to the truth of its results. It would seem to be full time that vague and barren disputations concerning materialism and spiritualism should end, and that, instead of continuing such fruitless and unprofitable discussion, men should apply themselves diligently to discover, by direct interrogation of Nature, how much matter can do without spiritual help. Let each investigator pursue the method of research which most suits the bent of his genius, and here, as in other departments of science, let each system be judged by its fruits, which cannot fail in the end to be the best sponsors and sureties for its truth. — MAUDSLEY *Body and Mind*, pref., p. 6. (A., 1898.)

2989. SCIENCE IN ITS PRACTICAL BEARINGS—*The Material Triumphs of the Nineteenth Century.* — When our century, with justice, is called the age of natural science, when we look with pride upon the immensely important progress made in all its branches, we are generally in the habit of thinking more of immediate practical results, and less of the extension of our general knowledge of Nature. We call to mind the complete reform, so infinitely rich in consequences to human intercourse, which has been effected by the development of machinery, by railways, steamships, telegraphs, and other inventions of physics. Or we think of the enormous influence which chemistry has brought to bear upon medicine, agriculture, and upon all arts and trades.—HAECKEL *History of Creation*, vol. i, ch. 1, p. 2. (K. P. & Co., 1899.)

2990. SCIENCE IN PRESENCE OF THE OLD MYSTERY—*Infinite Purpose Associated with Endless Material Evolution.*—The wave of life which is now passing over our earth is but a ripple in the sea of life within the solar system; this sea of life is itself but as a wavelet on the ocean of eternal life throughout the universe. Inconceivable, doubtless, are these infinities of time and space, of matter, of motion, and of life. Inconceivable that the whole universe can be for all time the scene of the operation of infinite personal power, omnipresent, all-knowing! Utterly incomprehensible how infinite purpose can be associated with endless material evolution! But it is no new thought, no modern discovery, that we

are thus utterly powerless to conceive or comprehend the idea of an Infinite Being, almighty, all-knowing, omnipresent, and eternal, of whose inscrutable purpose the material universe is the unexplained manifestation. Science is in presence of the old, old mystery; the old, old questions are asked of her: "Canst thou by searching find out God? canst thou find out the Almighty unto perfection? It is as high as heaven; what canst thou do? deeper than hell; what canst thou know?" (Job xi, 7.) And science answers these questions as they were answered of old: "As touching the Almighty, we cannot find him out" (Job xxxvii, 23).—PROCTOR *Our Place among Infinities*, p. 34. (L. G. & Co., 1897.)

2991. SCIENCE, INSTRUCTION IN—*Progress of Germany through Scientific Education.*—If we investigate more closely the causes of the wonderful strides which Germany has made in all directions, we shall find that it is not due to the mystified and inexplicable ponderous phrases of their philosophers, nor to the beautiful and descriptive verses of their poets, nor yet to the system of federation and the great victories due to their statesmen and warriors. On the other hand, we will find that this progress is due directly to the system of instruction in science, which during the last hundred years has permeated all parts of the German Empire, dominating the faculties of its universities and absorbing all the energies of its technical schools. And among the sciences whose teachings have made this great progress possible chemistry easily stands at the head.

Directly springing from the instruction given in the universities and technical schools have grown the great industries which have pushed the German people to the forefront in many of the leading pursuits of civilized life.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 16).

2992. SCIENCE IS EXACT, SYSTEMATIZED KNOWLEDGE—*Material for Science Gained Even by Savages.*—Science is exact, regular, arranged knowledge. Of common knowledge savages and barbarians have a vast deal, indeed the struggle of life could not be carried on without it. The rude man knows much of the properties of matter, how fire burns and water soaks, the heavy sinks and the light floats, what stone will serve for the hatchet and what wood for its handle, which plants are food and which are poison, what are the habits of the animals that he hunts or that may fall upon him. He has notions how to cure, and much better notions how to kill. In a rude way he is a physicist in making fire, a chemist in cooking, a surgeon in binding up wounds, a geographer in knowing his rivers and mountains, a mathematician in counting on his fingers. All this is knowledge, and it was on these foundations that science proper began to be built up, when the art of writing had come in and society had entered on the civilized stage.—TYLOR *Anthropology*, ch. 13, p. 309. (A., 1899.)

2993. SCIENCE JUSTIFIES PRACTICAL SAGACITY—*Solidification of Alpine Snow.*—Upon the wall of rock was placed a second wall of snow, which dwindled to a pure knife-edge at the top. It was white, of very fine grain, and a little moist. How to pass this snow catenary I knew not, for I did not think a human foot could trust itself upon so frail a support. Bennen's practical sagacity, however, came into play. He tried the snow by squeezing it with his foot, and to my astonishment began to cross it. Even after the pressure of his feet the space he had to stand on did not exceed a handbreadth. I followed him, exactly as a boy walking along a horizontal pole, with toes turned outwards. Right and left the precipices were appalling. We reached the opposite rock, and an earnest smile rippled over Bennen's countenance as he turned towards me. He knew that he had done a daring thing, tho not a presumptuous one. "Had the snow," he said, "been less perfect, I should not have thought of attempting it; but I knew after I had set my foot upon the ridge that we might pass without fear."

It is quite surprising what a number of things the simple observation made by Faraday in 1846 [see REGELATION] enables us to explain. Bennen's instinctive act is justified by theory. The snow was fine in grain, pure, and moist. When pressed, the attachments of its granules were innumerable, and their perfect cleanness enabled them to freeze together with a maximum energy. It was this freezing which gave the mass its sustaining power.—TYNDALL *Hours of Exercise in the Alps*, ch. 9, p. 99. (A., 1898.)

2994. SCIENCE, MODERN, IS PRACTICAL—*Bacteriology Studies Prevention of Disease—Life-and-Death Battles under the Microscope.*—The object of modern bacteriology is not merely to accumulate tested facts of knowledge, nor only to learn the truth respecting the biology and life-history of bacteria. These are most important things from a scientific point of view. But they are also a means to an end; that end is the prevention of preventable diseases and the treatment of any departure from health. In a science not a quarter of a century old much has already been accomplished in this direction. The knowledge acquired of, and the secrets learned from, these tiny vegetable cells, which have such potentiality for good or evil, have been, in some degree, turned against them. When we know what favors their growth and vitality and virulence, we know something of the physical conditions which are inimical to their life; when we know how to grow them, we also know how to kill them.—NEWMAN *Bacteria*, ch. 9, p. 322. (G. P. P., 1899.)

2995. SCIENCE, NATURAL, THE LIMITS OF—Physics, as the name itself implies, can only deduce the phenomena of the physical world from the properties of matter: the highest aim of experimental science is therefore to ascend to the existence of the laws, and progressively to generalize the same. Whatever lies beyond is no object for physical demonstration, it belongs to another order of more elevated speculations. Immanuel Kant, one of the few philosophers whom no one has yet accused of impiety, has, with rare sagacity, indicated the limits of physical explanation in his renowned "Essai sur la Théorie et la Construction des Cieux," Koenigsberg, 1775.—HUMBOLDT *Preface to French translation of the Cosmos.* (Translated for *Scientific Side-Lights.)*

2996. SCIENCE NEITHER PROVES NOR DENIES A GOD—*The Inconceivable May Still Be Fact—The Realities of Science Point to Infinite Purpose.*—So far as science is concerned, the idea of a personal God is inconceivable, as are all the attributes which religion recognizes in such a being. On the other hand, it should be admitted as distinctly, that science no more disproves the existence of infinite personal power or wisdom than she disproves the existence of infinite material energy (which on the contrary must be regarded as probable), or the existence of infinite space or time (which must be regarded as certain). . . . To the man of science, observing the operation of second causes in every process with which his researches deal, and finding no limit to the operation of such causes, however far back he may trace the chain of causation, the idea of a first cause is as inconceivable in its relation to observed scientific facts as is the idea of infinite space in its relation to the finite space to which the observations of science extend. Yet infinite space must be admitted; nor do I see how even that man of science who would limit his thoughts most rigidly to facts can admit that all things are of which he thinks, without having impressed upon him the feeling that, in some way he cannot understand, these things represent the operation of infinite purpose.—PROCTOR *Our Place among Infinities,* p. 2. (L. G. & Co., 1897.)

2997. SCIENCE NOT A REVELATION OF SPIRITUAL TRUTH—*No Moral Telescope to Make Discoveries in the Spiritual Realm.*—Without the testimony of an authentic messenger from heaven, I know nothing of heaven's counsels. I never heard of any moral telescope that can bring to my observation the doings or the deliberations which are taking place in the sanctuary of the Eternal. I may put into the registers of my belief all that comes home to me through the senses of the outer man, or by the consciousness of the inner man. But neither the one nor the other can tell me of the purposes of God; can tell me of the transactions or the designs of his sublime monarchy; can tell me of the goings forth of Him who is from everlasting unto everlasting; can tell me of the march and the movements of that great administration which embraces all worlds, and takes into its wide and comprehensive survey the mighty roll of innumerable ages. . . . The more that this spirit [the modesty of true science] is cultivated and understood, the more will it be found in alliance with that spirit, in virtue of which all that exalteth itself against the knowledge of God is humbled, and all lofty imaginations are cast down, and every thought of the heart is brought into the captivity of the obedience of Christ.—CHALMERS *Astronomical Discourses,* disc. 2, p. 65. (R. Ct., 1848.)

2998. SCIENCE NOT TO BE ESTIMATED BY MERE UTILITY—There is no science whose value can be adequately estimated by economists and utilitarians of the lower order. Its true quantities cannot be represented by arithmetical figures or monetary tables; for its effects on mind must be as surely taken into account as its operations on matter, and what it has accomplished for the human intellect as certainly as what it has done for the comforts of society or the interests of commerce. Who can attach a marketable value to the discoveries of Newton?—MILLER *Old Red Sandstone,* ch. 10, p. 177. (G. & L., 1851.)

2999. SCIENCE OF NATURE—*A Universal System.*—This, then, is what is designed to be conveyed by the "foundation of astronomical or cosmical physics." It means the establishment of a science of Nature whose conclusions are not only presumed by analogy, but are ascertained by observation, to be valid wherever light can travel and gravity is obeyed—a science by which the nature of the stars can be studied upon the earth, and the nature of the earth can be made better known by study of the stars—a science, in a word, which is, or aims at being, one and universal, even as Nature—the visible reflection of the invisible highest Unity—is one and universal.—CLERKE *History of Astronomy,* pt. ii, ch. 1, p. 176. (Bl., 1893.)

3000. SCIENCE OF POLITICS—*Knowledge of Social Laws Still Rudimentary.*—The world is not so prosperous or so happy as that we should readily or willingly believe in the exhaustion of the means which are at our disposal for its better guidance. Especially in the great science of politics, which investigates the complicated forces whose action and reaction determine the condition of organized societies of men, we are still standing, as it were, only at the break of day. Our command over the external elements of Nature is, beyond all comparison, in advance of our command over the resources of human character.—ARGYLL *Reign of Law,* ch. 7, p. 228. (Burt.)

3001. SCIENCE OVERCOMES DIFFICULTIES — *Color-photography.* — It has long been the dream of photographers to discover some mode of obtaining pictures which shall reproduce all the colors of Nature without the intervention of the artist's manipulation. This was seen to be exceedingly difficult, if not impossible, because the chemical action of colored light has no power to produce pigments of the same color as the light itself, without which a photograph in natural colors would seem to be impossible. Nevertheless, the problem has been solved, but in a totally different manner; that is, by the principle of "interference," instead of by that of chemical action. This principle was discovered by Newton, and is exemplified in the colors of the soap-bubble, and in those of mother-of-pearl and other iridescent objects. It depends on the fact that the differently colored rays are of different wave-lengths, and the waves reflected from two surfaces half a wave-length apart neutralize each other and leave the remainder of the light colored. If, therefore, each differently colored ray of light can be made to produce a corresponding minute wave-structure in a photographic film, then each part of the film will reflect only light of that particular wave-length, and therefore of that particular color, that produced it. This has actually been done by Professor Lippmann, of Paris, who published his method in 1891; and in a lecture before the Royal Society in April, 1896, he fully described it and exhibited many beautiful specimens.—WALLACE *The Wonderful Century,* ch. 5, p. 36. (D. M. & Co., 1899.)

3002. SCIENCE PERSONIFIES FORCES—*Laws Invested with Attributes of Mind.* —The universal prevalence of this idea of purpose in Nature is indicated by the irresistible tendency which we observe in the language of science to personify the forces, and the combinations of force by which all natural phenomena are produced. It is a great injustice to scientific men—too often committed—to suspect them of unwillingness to accept the idea of a personal Creator merely because they try to keep separate the language of science from the language of theology. But it is curious to observe how this endeavor constantly breaks down—how impossible it is in describing physical phenomena to avoid the phraseology which identifies them with the phenomena of mind, and is molded on our own conscious personality and will. It is impossible to avoid this language simply because no other language conveys the impression which innumerable structures leave upon the mind. Take, for example, the word "contrivance." How could science do without it? How could the great subject of animal mechanics be dealt with scientifically without continual reference to law as that by which, and through which, special organs are formed for the doing of special work? What is the very definition of a machine? Machines do not increase force, they only adjust it. The very idea and essence of a machine is that it is a contrivance for the distribution of force with a view to its bearing on special purposes. A man's arm is a machine in which the law of leverage is supplied to the vital force for the purposes of prehension. . . . Anatomy supplies an infinite number of similar examples. It is impossible to describe or explain the facts we meet with in this or in any other branch of science without investing the "laws" of Nature with something of that personality which they do actually reflect, or without conceiving of them as partaking of those attributes of mind which we everywhere recognize in their working and results.—ARGYLL *Reign of Law,* ch. 2, p. 54. (Burt.)

3003. SCIENCE, PHYSICAL VS. MENTAL—*Individuality of Consciousness.*—The phenomena of the external world are so palpable and so easily described that the experience of one observer suffices to render the facts he has witnessed intelligible and probable to all. The phenomena of the internal world, on the contrary, are not capable of being thus described; all that the prior observer can do is to enable others to repeat his experience. In the science of mind we can neither understand nor be convinced of anything at second hand. Here testimony can impose no belief, and instruction is only instruction as it enables us to teach ourselves. A fact of consciousness, however accurately observed, however clearly described, and however great maybe our confidence in the observer, is for us as zero, until we have observed and recognized it ourselves. Till that be done we cannot realize its possibility, far less admit its truth. Thus it is that, in the philosophy of mind, instruction can do little more than point out the position in which the pupil ought to place himself, in order to verify, by his own experience, the facts which his instructor proposes to him as true.—HAMILTON *Metaphysics,* lect. 1, p. 11. (G. & L., 1859.)

3004. SCIENCE, PRACTICAL—*A Message of, to Man about Himself.*—What science has to say about himself is of transcendent interest to man, and the practical bearings of this theme are coming to be more vital than any on the field of knowledge.—DRUMMOND *Ascent of Man,* pref., p. 5. (J. P., 1900.)

3005. ——— ——— *Utility Sought and Attained—Treatment of Soil to Avoid Frost.* —From the fact of the great heat-absorption by dark soils, the increased loss of heat by night necessarily follows. In such districts the occurrence of night frosts is promoted in a high degree, a result that is of the greatest importance to vegetation. Experiments on a great scale have been made in the black, low grounds of North Germany—for instance, in Drömling, the

great marsh at the source of the rivers Aller and Ohre. These resulted in the interesting discovery that on clear nights the nightly minimal temperature was several degrees lower upon the uncovered black moor earth than upon neighboring places close by of a different character of soil. But if the moor soil was covered with a layer of sand ten centimeters in thickness, as is the procedure in tilling the moor dikes, the difference in the radiation of heat immediately disappeared, so that this greatest danger to vegetation was materially lessened.—ASSMAN, *article on Klima*, p. 157, in KIRCHHOFF'S *Anleitung zur deutschen Landes- und Volksforschung.* (Translated for *Scientific Side-Lights.*)

3006. SCIENCE REPLACING SUPERSTITION—*Observation and Reasoning Correct Disorders of Imagination.*—Among nations least advanced in civilization the imagination revels in strange and fantastic creations, and, by its predilection for symbols, alike influences ideas and language. Instead of examining, men are led to conjecture, dogmatize, and interpret supposed facts that have never been observed. The inner world of thought and of feeling does not reflect the image of the external world in its primitive purity. That which in some regions of the earth manifested itself as the rudiments of natural philosophy, only to a small number of persons endowed with superior intelligence, appears in other regions, and among entire races of men, to be the result of mystic tendencies and instinctive intuitions. An intimate communion with Nature, and the vivid and deep emotions thus awakened, are likewise the source from which have sprung the first impulses toward the worship and deification of the destroying and preserving forces of the universe. But by degrees, as man, after having passed through the different gradations of intellectual development, arrives at the free enjoyment of the regulating power of reflection, and learns by gradual progress, as it were, to separate the world of ideas from that of sensations, he no longer rests satisfied merely with a vague presentiment of the harmonious unity of natural forces; thought begins to fulfil its noble mission, and observation, aided by reason, endeavors to trace phenomena to the causes from which they spring.—HUMBOLDT *Cosmos*, vol. i, int., p. 37. (H., 1897.)

3007. SCIENCE, ROMANCE OF—*The Story of Man.*—The last romance of science, the most daring it has ever tried to pen, is the story of the ascent of man. Withheld from all the wistful eyes that have gone before, whose reverent ignorance forbade their wisest minds to ask to see it, this final volume of natural history has begun to open with our century's close.—DRUMMOND *Ascent of Man*, ch. 1, p. 1. (J. P., 1900.)

3008. SCIENCE, SPURIOUS, IN EARLY EGYPT—*A Record of Dead Facts.*—Of science properly so called the Egyptian had none. He claimed to have made records of natural facts for ages, such, for example, as astronomical observations, which as he boasted, had been kept up for six thousand centuries. But out of this vast storehouse of accumulated data not a single theory explanatory of the motions of the heavenly bodies ever emerged. He heaped up facts as he did the stones of the great pyramid, with infinite labor, and over a great interval of time, but the mountain of facts was as lifeless as the mountain of stone. It was dead, it held the dead, and there was no health in it.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 2, p. 3[illegible] (J. W., 1898.)

3009. SCIENCE TEACHES PROTECTION—*Pasteurization or Sterilization of Milk*—The bacteria causing the diseases conveyable by milk succumb at much lower temperatures than the boiling-point. Advantage is taken of this in the process known as "pasteurization." By this method the milk is heated to 167-185° F. (75-85° C.). Such a temperature kills harmful microbes, because 75° C. is decidedly above their average thermal death-point, and yet the physical changes in the milk are practically nil because 85° C. does not relatively approach the boiling-point. There is no fixed standard for pasteurization, except that it must be above the thermal death-point of pathogenic bacteria, and yet below the boiling point. As a matter of fact, 158° F. (70° C.) will kill all souring bacteria as well as disease-producing organisms found in milk. If the milk is kept at that temperature for ten or fifteen minutes we say it has been "pasteurized." If it has been boiled with or without pressure, for half an hour we say it has been "sterilized."—NEWMAN *Bacteria*, ch. 6, p. 208. (G. P. P., 1899.)

3010. SCIENCE TEACHES THE NATURALNESS OF RELIGION—*Religion Shows the Supernaturalness of Nature.*—No science contributes to another without receiving a reciprocal benefit. And even as the contribution of science to religion is the vindication of the naturalness of the supernatural, so the gift of religion to science is the demonstration of the supernaturalness of the natural. Thus, as the supernatural becomes slowly natural, will also the natural become slowly supernatural, until in the impersonal authority of law men everywhere recognize the authority of God.—DRUMMOND *Natural Law in the Spiritual World*, pref., p. 20. (H. Al.)

3011. SCIENCE THE GREAT EXPOSITOR—*Religion Purified by Science—Science Exalted by Religion.*—Herbert Spencer points out, with how much truth need not now be discussed, that the purification of religion has always come from science. It is very apparent, at all events, that an immense debt must soon be contracted. The shifting of the furnishings will be a work of time.

But it must be accomplished. And not the least result of the process will be the effect upon science itself. No department of knowledge ever contributes to another without receiving its own again with usury—witness the reciprocal favors of biology and sociology. From the time that Comte defined the analogy between the phenomena exhibited by aggregations of associated men and those of animal colonies the science of life and the science of society have been so contributing to one another that their progress since has been all but hand-in-hand. A conception borrowed by the one has been observed in time finding its way back, and always in an enlarged form, to further illuminate and enrich the field it left. So must it be with science and religion. If the purification of religion comes from science, the purification of science, in a deeper sense, shall come from religion. The true ministry of Nature must at last be honored, and science take its place as the great expositor.—DRUMMOND *Natural Law in the Spiritual World,* int., p. 27. (H. Al.)

3012. SCIENCE, THE STUDY OF, AWAKENS THE THIRST FOR KNOWLEDGE—Recognition of the truth is the object of every science, but research into natural science has the advantage of being calculated to put into practise and to confirm the striving after knowledge. In this respect it proves a specially valuable means of education. Even mathematics is inferior to it.—MAGNUS *Address as Rector (Rektoralsrede).* (Translated for *Scientific Side-Lights.)*

3013. SCIENCE TO BE CULTIVATED FOR ITS OWN SAKE—*Love of Truth a Sufficient Motive.*—This, then, is the core of the whole matter as regards science. It must be cultivated for its own sake, for the pure love of truth, rather than for the applause or profit that it brings. . . . Could we have seen these men at work, without any knowledge of the consequences of their work, what should we have thought of them? To the uninitiated in their day they might often appear as big children playing with soap-bubbles and other trifles. It is so to this hour. Could you watch the true investigator—your Henry or your Draper, for example—in his laboratory, unless animated by his spirit, you could hardly understand what keeps him there. Many of the objects which rivet his attention might appear to you utterly trivial, and if you were to ask him what is the use of his work the chances are that you would confound him. He might not be able to express the use of it in intelligible terms. He might not be able to assure you that it will put a dollar into the pocket of any human being, living or to come. That scientific discovery may put not only dollars into the pockets of individuals, but millions into the exchequers of nations, the history of science amply proves; but the hope of its doing so never was, and it never can be, the motive power of the investigator.—TYNDALL *Lectures on Light,* p. 213. (A., 1898.)

3014. SCIENCE, TRANSFORMATION OF—*Beginning of Nineteenth Century in Germany — Medieval Ideas Still Prevalent— "Phlogiston," the Fire Element.*—It is difficult for us to realize the condition of natural science as it existed in Germany, at least in the first twenty years of this century. Magnus was born in 1802; I myself nineteen years later; but when I go back to my earliest recollections, when I began to study physics out of the school-books in my father's possession, who was himself taught in the Cauer Institute, I still see before me the dark image of a series of ideas which seems now like the alchemy of the Middle Ages. Of Lavoisier's and of Humphry Davy's revolutionizing discoveries not much had got into the school-books. Altho oxygen was already known, yet phlogiston, the fire element, played also its part. Chlorin was still oxygenated hydrochloric acid; potash and lime were still elements. Invertebrate animals were divided into insects and reptiles, and in botany we still counted stamens.—HELMHOLTZ *Popular Lectures,* lect. 1, p. 10. (L. G. & Co., 1898.)

3015. SCIENCE, VICISSITUDES OF A—*The Early Days of Chemistry—Alchemists First Favored, Then Persecuted.*—Chemistry has been the wonder-child among the natural sciences. None of her sisters ever followed such objects of adventure, or ever fulfilled so strange a destiny as hers. There was a time when chemistry believed in all earnest that within the dark lap of Nature there was a secret treasure to be found called the philosopher's stone. At that time chemistry was in high esteem among the great of the earth, and was clothed in purple as long as avarice could entertain that belief; but when men imagined themselves betrayed in their hopes of discovering [the secret of transmuting the baser metals into] gold they offered the gallows and the wheel for its followers (frequently unworthy enough, it must be acknowledged). And, in fact, the church regarded the salvation of believers as endangered by these black arts, and hurled against them banns and bull.—PETTENKOFER *Lecture, Was bedeutet die Chemie für die Physiologie?* p. 4. (Translated for *Scientific Side-Lights.)*

3016. SCIENCES, INTERDEPENDENCE OF—*Medicine Developed Botany.*—The science of medicine, which was founded by Dioscorides in the school of Alexandria, when considered with reference to its scientific development, is essentially a creation of the Arabs, to whom the oldest, and at the same time one of the richest, sources of knowledge, that of the Indian physicians, had been early opened. Chemical pharmacy was created by the Arabs, while to them are likewise due the first official prescrip-

tions regarding the preparation and admixture of different remedial agents—the dispensing recipes of the present day. These were subsequently diffused over the south of Europe by the school of Salerno. Pharmacy and materia medica, the first requirements of practical medicine, led simultaneously, in two directions, to the study of botany and to that of chemistry. From its narrow sphere of utility and its limited application, botany gradually opened a wider and freer field, comprehending investigations into the structure of organic tissues and their connection with vital forces, and into the laws by which vegetable forms are associated in families, and may be distinguished geographically according to diversities of climate and differences of elevation above the earth's surface.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 210. (H., 1897.)

3017. SCIENTIST LOYAL TO OPPOSING CHURCH — *Copernicus Dedicates Great Discovery to the Pope.*—When Copernicus is describing, in his dedication to the pope, the origin of his work, he does not scruple to term the opinion generally expressed among theologians of the immobility and central position of the earth "an absurd acroama," and to attack the stupidity of those who adhere to so erroneous a doctrine. "If even," he writes, "any empty-headed babblers (ματαιολόγοι), ignorant of all mathematical science, should take upon themselves to pronounce judgment on his work through an intentional distortion of any passage in the Holy Scriptures . . . . he should despise so presumptuous an attack. It was, indeed, universally known that the celebrated Lactantius, who, however, could not be reckoned among mathematicians, had spoken childishly *(pueriliter)* of the form of the earth, deriding those who held it to be spherical. On mathematical subjects one should write only to mathematicians. In order to show that, deeply penetrated with the truth of his own deductions, he had no cause to fear the judgment that might be passed upon him, he turned his prayers from a remote corner of the earth to the head of the church, begging that he would protect him from the assaults of calumny, since the church itself would derive advantage from his investigations on the length of the year and the movements of the moon." Astrology and improvements in the calendar long procured protection for astronomy from the secular and ecclesiastical powers, as chemistry and botany were long esteemed as purely subservient auxiliaries to the science of medicine.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 307. (H., 1897.)

3018. SCIENTIST MUST BECOME AS A LITTLE CHILD—In the law book of research in natural science we read the same command as in the Scriptures, "Verily I say unto you, except ye become as a little child, ye shall not enter into the kingdom of heaven." Accordingly, we see the investigator everywhere making an earnest effort to return to the standpoint of a child that forgets all sorrow as soon as something that moves is furnished him to look at, it matters little what—a tin plate set to spin, or a kitten at her play. But, of course, between the manner in which the scientist marvels at these phenomena, and that of the child, there lies the chasm that separates the moral value of a human being, ripened by experience, from the innocence of a child.—DU BOIS-REYMOND, *a lecture, Tierische Bewegung.* (Translated for *Scientific Side-Lights.)*

3019. SCIENTISTS FOILED BY A KING— *The "April Moon"—Laplace Astounded—Arago Seeks Instruction from Gardeners.*—"I am delighted to see you collected round me," said Louis XVIII. one day to the members composing a deputation from the *Bureau des Longitudes,* who had gone to present to him the "Connaissance des Temps" and the "Annuaire," "for you will explain to me what the April moon is, and its mode of action on the crops." Laplace, to whom he more especially addressed these words, was astounded. He who had written so much on the moon had never, in fact, thought of the April moon. He consulted all his neighbors by a look, but seeing nobody disposed to speak, he determined to reply himself. "Sire, the April moon does not hold any place in astronomical theories; we are not, then, able to satisfy the curiosity of your Majesty." In the evening, during his game, the king was very merry over the embarrassment in which he had placed the members of his *Bureau des Longitudes.* Laplace heard of it, and went to ask Arago if he could enlighten him about this famous April moon, which had been the subject of such a disagreeable mishap. Arago went for information to the gardeners of the *Jardin des Plantes.*—FLAMMARION *Popular Astronomy*, bk. ii, ch. 8, p. 174. (A.)

3020. SCIENTISTS READ KING'S RIDDLE—*The "April Moon"—Popular Observation True—Popular Theory False.*—Gardeners give the name of "April moon" to the moon which commences in April and becomes full either at the end of that month or, more usually, in the course of May. In popular opinion the light of the moon in April and May exercises an injurious action on the young shoots of plants. They are confident of having observed that on the nights when the sky is clear the leaves and buds exposed to this light are blighted—that is to say, are frozen—altho the thermometer in the atmosphere stands at several degrees above zero. They add, however, that if a clouded sky arrests the lunar rays, and prevents them reaching the plants, the same effects no longer take place, in circumstances of temperature, moreover, perfectly similar. These phenomena seem to indicate that the light of our satellite may be endowed with a

certain freezing effect. Nevertheless, in directing the largest lenses and reflectors towards the moon, and then placing in their focus very delicate thermometers, nothing has ever been perceived which could justify such a singular conclusion. . . . The following is the explanation:

The physicist Wells first ascertained that at night objects may acquire a temperature different from that of the atmosphere which surrounds them. This important fact is now proved. If we place in the open air small pieces of cotton, eiderdown, etc., we often find that their temperature is six or seven or even eight degrees centigrade below the temperature of the surrounding atmosphere. Vegetables are in the same case. We cannot, then, judge of the cold which a plant has experienced in the night by the sole indications of a thermometer suspended in the atmosphere. Place a thermometer flat on the ground: its temperature will descend below that of the air, if the sky is very clear. A plant may be much frozen, altho the air may be constantly maintained at several degrees above zero [centigrade].

These differences of temperature are only produced in perfectly clear weather. If the sky is cloudy the difference disappears entirely or becomes imperceptible. In the nights of April and May the temperature is often only a few degrees above zero [centigrade]. At that time plants exposed to the light of the moon—that is to say, to a clear sky—may be frozen, notwithstanding the thermometer. If the moon, on the contrary, does not shine, if the sky is cloudy, the temperature of the plants not descending below that of the atmosphere, they would not freeze—at least not till the thermometer has marked zero. It is, then, true, as the gardeners assert, that with quite similar thermometric circumstances a plant may be frozen or not, according as the moon is visible or hidden behind clouds. If they are mistaken, it is only in the conclusions—that is, in attributing the effect to the light of the moon. The lunar light is here but an index of a clear atmosphere: it is in consequence of the clearness of the sky that the nocturnal freezing of the plants is effected [through the radiation of their heat into space]. The moon contributes in no way to the result. Whether it is set or on the horizon the phenomenon would be the same.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 8, p. 174. (A.)

3021. SCULPTURE AND PAINTING, INFANCY OF—*Modern Work of Untaught Rustics Like Ancient Idols.*—The painter's and sculptor's art seems to have arisen in the world from the same sort of rude beginnings which are still to be seen in children's attempts to draw and carve. The sheets of bark or skins on which barbarous tribes have drawn men and animals, guns and boats, remind us of the slates and barn doors on which English children make their early trials in outline. Many of these children will grow up and go through their lives without getting much beyond this childish stage. The clergyman of a country parish some years ago set the cottagers to amuse themselves with carving in wood such figures as men digging or reaping. They produced figures so curiously uncouth, and in style so like the idols of barbarous tribes, that they were kept as examples of the infancy of sculpture, and are now to be seen in the museum of Kew Gardens.—TYLOR *Anthropology*, ch. 12, p. 300. (A., 1899.)

3022. SCULPTURE, GREEK, INDEBTED TO ASSYRIANS AND EGYPTIANS—*Painting of Ancient Statuary.*—Greek art is sometimes written of as tho it had itself begun in the rudest stage, with clumsy idols of wood and clay, till by efforts of their own surpassing genius the Greek sculptors came to hew in marble the forms which are still the wonders of the world. But great as Greek genius was, it never did this. The Greek nations had been for ages in contact with the older civilizations of the Mediterranean; their starting-point was to learn what art could do in Egypt, Phenicia, Babylonia: and then their genius set them free from the hard old conventional forms, leading them to model life straight from Nature, and even to fashion in marble shapes of ideal strength and grace. The Egyptian sculptors would not spoil polished granite with paint, but many of their statues were colored, and there are traces of paint left on the Assyrian sculptures and on Greek statues, so that we are apt to have a wrong idea of a Greek temple, as tho its marble gods and goddesses used to be of the glaring whiteness of a modern sculpture-gallery. The Greek terra-cotta statuettes in the British Museum are models of antique female grace in form and costume, only wanting the lost color restored to make them the prettiest things in the world.—TYLOR *Anthropology*, ch. 12, p. 303. (A., 1899.)

3023. SEA, EARTHQUAKES ORIGINATING BENEATH—*Steam the Motive Power of Volcanic Eruptions.*—It may here be remarked that a very large proportion of the destructive earthquakes of the world have originated beneath the sea, along the base of continental domes which are unusually steep. On the top of these slopes, which, for example, form the backbone of Japan and Peru, we find volcanic vents. Where strong folding of the earth's crust has taken place, as in the Alps and Himalayas, but at a distance from the sea, earthquakes may be frequent whilst volcanic eruptions are unknown. Earthquakes occur where rock-folding is in progress, and volcanoes are found where maxima of folding have taken place, providing the site of these is sufficiently near large bodies of water, which supply the moisture which, when converted into steam, is the motive power for all great eruptions.—MILNE *Earthquakes*, ch. 17, p. 285. (A., 1899.)

3024. SEA, MOUNTAIN CAST INTO—*Earthquake in Hindustan.*—The town of Chittagong, in Bengal, was violently shaken by an earthquake on the 2d of April, 1762, the earth opening in many places and throwing up water and mud of a sulfureous smell. At a place called Bardavan a large river was dried up; and at Bar Charra, near the sea, a tract of ground sunk down and 200 people, with all their cattle, were lost. It is said that sixty square miles of the Chittagong coast suddenly and permanently subsided during this earthquake, and that Ces-lung-Toom, one of the Mug Mountains, entirely disappeared, and another sank so low that its summit only remained visible. Four hills are also described as having been variously rent asunder, leaving open chasms from thirty to sixty feet in width. Towns which subsided several cubits were overflowed with water; among others, Deep Gong, which was submerged to the depth of seven cubits. Two volcanoes are said to have opened in the Secta Cunda Hills. The shock was also felt at Calcutta. While the Chittagong coast was sinking, a corresponding rise of the ground took place at the island of Ramree and at Cheduba.—LYELL *Principles of Geology,* bk. ii, ch. 29, p. 494. (A., 1854.)

3025. SEA-SHELLS ABOVE HIGH-WATER MARK—*Elevation of Land in Earthquake.*—The most remarkable effect of this earthquake [the Chilean earthquake in 1835] was the permanent elevation of the land; it would probably be far more correct to speak of it as the cause. There can be no doubt that the land round the Bay of Concepcion was upraised two or three feet; but it deserves notice that owing to the wave having obliterated the old lines of tidal action on the sloping sandy shores, I could discover no evidence of this fact, except in the united testimony of the inhabitants, that one little rocky shoal, now exposed, was formerly covered with water. At the island of S. Maria (about thirty miles distant) the elevation was greater; on one part, Captain Fitz Roy found beds of putrid mussel-shells still adhering to the rocks, ten feet above high-water mark: the inhabitants had formerly dived at low-water spring-tides for these shells. The elevation of this province is particularly interesting from its having been the theater of several other violent earthquakes, and from the vast numbers of sea-shells scattered over the land, up to a height of certainly 600, and, I believe, of 1,000 feet. At Valparaiso, as I have remarked, similar shells are found at the height of 1,300 feet: it is hardly possible to doubt that this great elevation has been effected by successive small uprisings, such as that which accompanied or caused the earthquake of this year, and likewise by an insensibly slow rise, which is certainly in progress on some parts of this coast.—DARWIN *Naturalist's Voyage around the World,* ch. 14, p. 310. (A., 1898.)

3026. SEA-WAVES UPON THE LAND—*Earthquake Piling up Waters—Ships Driven Inland.*—At the earthquake in St. Thomas, in 1868, it is said that the water receded shortly before the first shock. When it returned, after the second shock, it was sufficient to throw the U. S. ship "Monongahela" high and dry. Another American ship, the "Wateree," was also lost in 1868 by being swept a quarter of a mile inland by the sea-wave which inundated Arica. The sea-waves of 1877 removed it still further inland. Much of the great destruction which occurred at the time of the great Lisbon earthquake was due to a series of great sea-waves, thirty to sixty feet higher than the highest tide, which swamped the town. These came in about an hour after the town had been shattered by the motion of the ground. The first motion in the waters was their withdrawal, which was sufficient to completely uncover the bar at the mouth of the Tagus. At Cadiz, the first wave, which was the greatest, is said to have been sixty feet in height. Fortunately the devastating effect which this would have produced was partially warded off by cliffs.—MILNE *Earthquakes,* ch. 9, p. 165. (A., 1899.)

3027. SECLUSION OF WOMEN—*Its Tendency to Refinement.*—The seclusion of women and their always eating apart by a roundabout way tended to their refinement and advancement and protection. It called for more services, and time in service. It consumed the hours in organized and regulated labor. It was discipline. In this coterie were included frequently the children and the old men. It is said that in times of scarcity the women were pinched with hunger first, but no one ever heard of a cook starving to death. This seclusion is also an evidence of the great independence and self-help developed in the priscan women.—MASON *Woman's Share in Primitive Culture,* ch. 10, p. 235. (A., 1894.)

3028. SECRETIVENESS TOWARD SUPERIORS—The impulse to conceal is more apt to be provoked by superiors than by equals or inferiors. How differently do boys talk together when their parents are not by! Servants see more of their masters' characters than masters of servants'. Where we conceal from our equals and familiars, there is probably always a definite element of prudential prevision involved. Collective secrecy, mystery, enters into the emotional interest of many games, and is one of the elements of the importance men attach to freemasonries of various sorts, being delightful apart from any end.—JAMES *Psychology,* vol. ii, ch. 24, p. 433. (H. H. & Co., 1899.)

3029. SECRET OF COMETS DISCOVERED — *Self-luminous Bodies — Their Light from Glowing Gas.*—The first suc-

cessful application of the spectroscope to comets was by Donati in 1864. A comet discovered by Tempel, July 4, brightened until it appeared like a star somewhat below the second magnitude, with a feeble tail 30° in length. It was remarkable as having, on August 7, almost totally eclipsed a small star—a very rare occurrence. On August 5 Donati admitted its light through his train of prisms, and found it, thus analyzed, to consist of three bright bands—yellow, green, and blue—separated by wider dark intervals. This implied a good deal. Comets had previously been considered, as we have seen, to shine mainly, if not wholly, by reflected sunlight. They were now perceived to be self-luminous, and to be formed, to a large extent, of glowing gas. The next step was to determine what kind of gas it was that was thus glowing in them; and this was taken by Dr. Huggins in 1868. . . . All the eighteen comets tested by light-analysis, between 1868 and 1880, showed the typical hydrocarbon spectrum common to the whole group of those compounds, but probably due immediately to the presence of acetylene.—CLERKE *History of Astronomy,* pt. ii, ch. 10, p. 414. (Bl., 1893.)

3030. SECRETS REVEALED—*Foreign Substances in the Body Shown by Roentgen Rays—The Mercy of Civilization.*—Flesh and skin are transparent in moderate thicknesses, while bone is opaque. Hence, if the rays [Roentgen] are passed through the hand the bones cast a shadow, tho an invisible one; and as, most fortunately, the rays act upon photographic plates almost like ordinary light, hands or other parts of the body can be photographed by their shadows, and will show the bones by a much darker tint. Hence their use in surgery, to detect the exact position of bullets or other objects embedded in the flesh or bone. A needle which penetrated the knee-joint and then broke off, leaving a portion embedded which set up inflammation, and might have necessitated the loss of the limb, was shown so accurately that a surgeon cut down to it and got it out without difficulty.—WALLACE *The Wonderful Century,* ch. 5, p. 40. (D. M. & Co., 1899.)

3031. SECURITY BY PRECAUTION—*Disinfection of Milk Possible—Sterilizing by Heat.*—If for practical purposes we look upon all milk derived from tubercular udders as highly infective, we may adopt a comparatively simple and efficient remedy. To avoid all danger it is sufficient to bring the milk to a boil for a few minutes before it is consumed; in fact, the temperature of 85° C. (160° F.) prolonged for five minutes kills all bacilli. The common idea that boiled milk is indigestible, and that the boiling causes it to lose much of its nutritive value, is largely groundless.—NEWMAN *Bacteria,* ch. 6, p. 197. (G. P. P., 1899.)

3032. SECURITY FROM INFECTION—*Putrefaction within the Law of Cause and Effect—Bacteria.*—Our knowledge here, as elsewhere in connection with this subject, has been vastly extended by Professor Cohn, of Breslau. "No putrefaction," he says, "can occur in a nitrogenous substance if its bacteria be destroyed and new ones prevented from entering it. Putrefaction begins as soon as bacteria, even in the smallest numbers, are admitted either accidentally or purposely. It progresses in direct proportion to the multiplication of the bacteria, it is retarded when they exhibit low vitality, and it is stopped by all influences which either hinder their development or kill them. All bactericidal media are therefore antiseptic and disinfecting."—TYNDALL *Floating Matter of the Air,* essay 5, p. 287. (A., 1895.)

3033. SEED-DISPERSAL—*Compensations for Vegetable Immobility—Children Given a New Start in Life.*—If each seed fell where it grew, the spread of the species would shortly be at an end. But Nature, working on the principle of cooperation, is once more redundant in its provisions. By a series of new alliances the offspring are given a start on distant and unoccupied ground; and so perfect are the arrangements in this department of the struggle for the life of others that single plants, immovably rooted in the soil, are yet able to distribute their children over the world. By a hundred devices the fruits and seeds when ripe are entrusted to outside hands—provided with wing or parachute and launched upon the wind, attached by cunning contrivances to bird and beast, or dropped into stream and wave and ocean-current, and so transported over the earth.—DRUMMOND *Ascent of Man,* ch. 7, p. 237. (J. P., 1900.)

3034. ——— ——— *Seed Distributor Rolled by Wind—The Russian Thistle.*—The Russian thistle begins its yearly growth in a simple, inoffensive way. The young plants are slender and succulent, but as they grow older they harden and spread out, becoming densely covered with sharp spines. When full grown they often reach a diameter of four or five feet, a majority of the specimens being distinctly rounded in outline. After the seeds have matured the stem twists around and breaks off, thus leaving the plant to roll wherever the wind blows it, dropping its seeds as it goes along. As one large plant sometimes produces 200,000 seeds, and may be blown for miles, one can readily imagine how soon a prairie region might be overrun by the pest, which grows so vigorously that it crowds out practically all plants with which it comes in competition.—WEED *Seed Travellers,* pt. i, p. 23. (G. & Co., 1899.)

3035. ——— ——— *Seeds Carried by Birds—The Holly—The American Currant.*—What holly loses in the size of its clusters, it gains in the brightness of its berries.

Against the dark green of the leaves, the berries stand out with great prominence. Their after-history is instructive enough. A holly-berry is gobbled up by a bird with ease. What of the seeds the berries contain? Does digestion, which in a bird is a tolerably rough and mechanical process, destroy the seeds? Not so. The seeds, encased each in its dense tough covering, resist even the digestion of the bird's gizzard and stomach, and they are passed on uninjured through the alimentary tract of the animal. Thus liberated, and the bird being the gainer by its digestion of the soft parts of the berries, the holly-seeds fall into the soil and grow up each in time to the holly-tree. Note again how this interaction between bird and fruit serves another useful purpose. Birds traverse leagues of country in their peregrinations. They may thus convey the holly-seeds to regions hundreds of miles from the parent tree whence the berries were plucked. . . . We owe much to the dispersal of seeds by such agencies. There is a plant of the New World, the American currant, which long ago was introduced into France, for the sake of the dark red juice of its berries, which was used to color wines. At Bordeaux this currant was extensively cultivated. Man introduced the plant, but mark the greater influence of the color of its fruits and the work of the birds. Now, the American currant is found universally throughout the south of France. It has spread also into Switzerland, and has reached the Tyrol. You can, therefore, prophesy with considerable safety regarding plants and their chances of distribution, when you see these fruits and learn the story of their distribution. Holly-berries have social associations dear to the hearts of us all. They possess, however, in their redness and in their attraction for bird-visitors, a romance that is all their own.—WILSON *Glimpses of Nature,* ch. 22, p. 73. (Hum., 1892.)

3036. ——— ——— *Seeds Flung Afar —The "Catapult Fruits."*—The calyx of sage, bergamot, and most other mints remains dry and stiff, as a cup to hold one to four little round nutlets as they ripen. . . . When dry, the plant behaves somewhat as follows: when the wind jostles the branches against each other, or when an animal of some kind hits the plant, this movement causes many of these cups to get caught; but the elastic stem comes suddenly back to its place, and in so doing flips a nutlet or more from its mouth one to six feet, somewhat as a boy would flip a pea with a pea-shooter. In our garden, July 2, when plants of sage, *Salvia interrupta,* were ripening their fruit, we found it difficult to collect any seeds, but seedlings were observed in abundance on every side of the plant, some to the distance of six feet. Plants dispersing seeds in this manner have been called catapult fruits.—BEAL *Seed Dispersal,* ch. 5, p. 50. (G. & Co., 1898.)

3037. ——— ——— *Seeds Scattered Like Snowflakes.*—The seeds of willow and poplar are covered with white downy silk, by means of which they are borne through the air in summer, often so filling it as to suggest a light snow-storm.—WEED *Seed Travellers,* ch. 1, p. 3. (G. & Co., 1899.)

3038. ——— ——— *Seeds Transported by Rivers.*—"The mountain stream or torrent," observes Keith, "washes down to the valley the seeds which may accidentally fall into it, or which it may happen to sweep from its banks when it suddenly overflows them. The broad and majestic river, winding along the extensive plain, and traversing the continents of the world, conveys to the distance of many hundreds of miles the seeds that may have vegetated at its source. Thus the southern shores of the Baltic are visited by seeds which grew in the interior of Germany, and the western shores of the Atlantic by seeds that have been generated in the interior of America." Fruits, moreover, indigenous to America and the West Indies, such as that of the *Mimosa scandens,* the cashewnut and others, have been known to be drifted across the Atlantic by the Gulf Stream, on the western coasts of Europe, in such a state that they might have vegetated had the climate and soil been favorable. Among these the *Guilandina Bonduc,* a leguminous plant, is particularly mentioned, as having been raised from a seed found on the west coast of Ireland.—LYELL *Principles of Geology,* bk. iii, ch. 37, p. 620. (A., 1854.)

3039. ——— ——— *Seeds Transported in Mud—Animals as Seed Distributors.*—Seeds and fruits of aquatic and bog plants that are floating, or in the mud of shallow water, are often carried by ducks, herons, swallows, muskrats, and other frequenters of such places, on their feet, beaks, or feathers, as they hastily leave one place for another. In this way seeds of water plantain, sedges, grasses, rushes, docks, arrowhead, pondweeds, duckweed, cat-tail flag, bur reed, bladderwort, water crowfoot, and many others are transported from one pond, lake, or stream to another. In some cases enough of a living plant may be detached and carried away to keep on growing. Darwin found on the feet of some birds six and three-quarter ounces of mud, in which were five hundred and thirty-seven seeds that germinated. Mud may be carried on the feet of land animals as well as on aquatic animals, not only from the ponds and bogs, but from the fields where seeds may have accumulated in the earth or washed down the slopes.—BEAL *Seed Dispersal,* ch. 7, p. 71. (G. & Co., 1898.)

3040. ——— ——— *Worms Bury Seeds in the Earth—Chambers under Ground Carefully Lined by Worm Builders.*—I found at Abinger, in Surrey, two burrows termina-

ting in similar chambers at a depth of 36 and 41 inches, and these were lined or paved with little pebbles about as large as mustard-seeds; and in one of the chambers there was a decayed oat-grain, with its husk. Hensen likewise states that the bottoms of the burrows are lined with little stones; and where these could not be procured, seeds, apparently of the pear, had been used, as many as fifteen having been carried down into a single burrow, one of which had germinated. We thus see how easily a botanist might be deceived who wished to learn how long deeply buried seeds remained alive, if he were to collect earth from a considerable depth, on the supposition that it could contain only seeds which had long lain buried. It is probable that the little stones, as well as the seeds, are carried down from the surface by being swallowed; for a surprising number of glass beads, bits of tile and of glass were certainly thus carried down by worms kept in pots; but some may have been carried down within their mouths. The sole conjecture which I can form why worms line their winter quarters with little stones and seeds, is to prevent their closely coiled-up bodies from coming into close contact with the surrounding cold soil; and such contact would perhaps interfere with their respiration, which is effected by the skin alone.—DARWIN *Formation of Vegetable Mould*, ch. 2, p. 33. (Hum., 1887.)

3041. SEEDS, PROFUSION OF—*Abundance in Nature.*—In producing seeds Nature is generous, often lavish. Most seeds are eaten by animals, or fall in places where they cannot germinate and produce plants, or fall in such numbers that most of them in growing are crowded and starved to death. A very small proportion fall on good ground, and succeed in becoming fruiting plants. A large plant of purslane produces one million two hundred and fifty thousand seeds; a patch of daisy fleabane, three thousand seeds to each square inch of space covered by a plant. The genuine student will not be satisfied till he has selected several different kinds of plants and counted, or estimated, the number of seeds produced by each, or the number of seeds furnished to the area covered by one or by several plants.—BEAL *Seed Dispersal*, ch. 7, p. 78. (G. & Co., 1898.)

3042. SEEING WITHOUT PERCEIVING—*Habitual Acts Automatic—Not Recognized by Consciousness Nor Held in Memory.*—When we move about in a room with the objects in which we are quite familiar, we direct our steps so as to avoid them, without being conscious what they are, or what we are doing; we see them, as we easily discover if we try to move about in the same way with our eyes shut, but we do not perceive them, the mind being fully occupied with some train of thought. In like manner, when we go through a series of familiar acts, as in dressing or undressing ourselves, the operations are really automatic; once begun, we continue them in a mechanical order, while the mind is thinking of other things; and if we afterward reflect upon what we have done, in order to call to mind whether we did or did not omit something, as for instance to wind up our watch, we cannot satisfy ourselves except by trial, even tho we had actually done what we were in doubt about. It is evident, indeed, that in a state of profound reverie or abstraction a person may, as a somnambulist sometimes does, see without knowing that he sees, hear without knowing that he hears, and go through a series of acts scarcely, if at all, conscious of them at the time, and not remembering them afterward.—MAUDSLEY *Body and Mind*, lect. 1, p. 23. (A., 1898.)

3043. SELECTION AMONG SIMULTANEOUS POSSIBILITIES—*Mind Works as a Sculptor on Marble—The Statue in the Stone.*—The mind is at every stage a theater of simultaneous possibilities. Consciousness consists in the comparison of these with each other, the selection of some, and the suppression of the rest by the reenforcing and inhibiting agency of attention. The highest and most elaborated mental products are filtered from the data chosen by the faculty next beneath, out of the mass offered by the faculty below that, which mass in turn was sifted from a still larger amount of yet simpler material, and so on. The mind, in short, works on the data it receives very much as a sculptor works on his block of stone. In a sense the statue stood there from eternity. But there were a thousand different ones besides it, and the sculptor alone is to thank for having extricated this one from the rest.—JAMES *Psychology*, vol. i, ch. 9, p. 288. (H. H. & Co., 1899.)

3044. SELECTION A PROPERTY OF LIFE—*Each Organ and Tissue Takes from the Blood Its Own Material—A Mystery of Science.*—Each tissue . . . takes from the common stream of nourishment the materials necessary for the building-up of new substance. From the blood bone selects the materials necessary for the formation of new bone; nerve from the same source gathers matter for the production of new nerve-tissue; muscle therefrom elaborates new muscle; cells of wondrously diverse kind, like buyers of many nations in a common market, select from the blood the special food or pabulum suited to their wants, and therefrom manufacture new cells—in short, the process of growth in man and in all animals of higher grade exemplifies the results of many varied operations effected by the tissues and organs of the body upon the common material offered to them in the shape of the nutrient blood. How this property of "selection" is exercised, or what is its exact nature, science knows not as yet. But the possession of this remarkable property of selecting and using appropriate material in the actions of life, explain it how

we may, constitutes one of the most consistent and clearly defined distinctions which can be drawn between the world of life and the great encompassing universe of nonliving matter.—ANDREW WILSON *Facts and Fictions of Zoology*, p. 30. (Hum., 1882.)

3045. SELECTION, ARTIFICIAL, THE MAGICIAN'S WAND—*Agriculturist May Mold His Flock at Pleasure.*—Youatt, who was probably better acquainted with the works of agriculturists than almost any other individual, and who was himself a very good judge of animals, speaks of the principle of selection as "that which enables the agriculturist not only to modify the character of his flock, but to change it altogether. It is the magician's wand, by means of which he may summon into life whatever form and mold he pleases."—DARWIN *Origin of Species*, ch. 1, p. 27. (Burt.)

3046. SELECTION, ARTIFICIAL, UNCONSCIOUSLY PRACTISED BY SAVAGES—If there exist savages so barbarous as never to think of the inherited character of the offspring of their domestic animals, yet any one animal particularly useful to them, for any special purpose, would be carefully preserved during famines and other accidents, to which savages are so liable, and such choice animals would thus generally leave more offspring than the inferior ones, so that in this case there would be a kind of unconscious selection going on.—DARWIN *Origin of Species*, ch. 1, p. 31. (Burt.)

3047. SELECTION IMPLIES REJECTION—Selection implies rejection as well as choice; and the function of ignoring, of inattention, is as vital a factor in mental progress as the function of attention itself. —JAMES *Psychology*, vol. ii, ch. 22, p. 371. (H. H. & Co., 1899.)

3048. SELECTION, NATURAL—*In Man Devoted to Mind—Tools Take the Place of New Organs.*—As an optical instrument, the eye had well-nigh reached extreme perfection in many a bird and mammal ages before man's beginnings; and the essential features of the human hand existed already in the hands of Miocene apes. But different methods came in when human intelligence appeared upon the scene. Mr. Spencer has somewhere reminded us that the crowbar is but an extra lever added to the levers of which the arm is already composed, and the telescope but adds a new set of lenses to those which already exist in the eye. This beautiful illustration goes to the kernel of the change that was wrought when natural selection began to confine itself to the psychical modification of our ancestors. In a very deep sense all human science is but the increment of the power of the eye, and all human art is the increment of the power of the hand.—FISKE *Destiny of Man*, ch. 7, p. 59. (H. M. & Co., 1900.)

3049. ——— ——— *Not a Cause—Forms To Be Selected Must First Exist—Not Origin, but Success of Variations.*—Natural selection can do nothing except with the materials presented to its hands. It cannot select except among the things open to selection. Natural selection can originate nothing; it can only pick out and choose among the things which are originated by some other law. Strictly speaking, therefore, Mr. Darwin's theory is not a theory on the origin of species at all, but only a theory on the causes which lead to the relative success or failure of such new forms as may be born into the world. It is the more important to remember this distinction, because it seems to me that Mr. Darwin himself frequently forgets it.—ARGYLL *Reign of Law*, ch. 5, p. 130. (Burt.)

3050. ——— ——— *Personified—Organisms Invested with Power of Self-creation—Plants and Animals Credited with Design.*—In one of those most able expositions of the doctrine of the origin of species by natural selection, by which Professor Huxley very early impressed the educated public with the scientific value of the new views which Mr. Darwin had opened out, he remarked that nothing had more strongly impressed him than the fact that they had completely disposed of the old teleological argument; the adaptations in organized structures which had been regarded as evidences of "design" being sufficiently accounted for as results of the "survival of the fittest." And this view of the case has been so zealously adopted by some of the younger advocates of the doctrine that they have gone the length of representing the plants and animals which exhibit them as having made themselves for the purposes which their organization is found to answer—as if they had the intelligent design which is denied to an universal Creator. When challenged to justify that language they represent it as merely "figurative"; their intention being only to show that, as natural selection gives a sufficient account of the adaptiveness, there is no need to seek for any other explanation of it.—CARPENTER *Nature and Man*, lect. 15, p. 435. (A., 1889.)

3051. ——— ——— *Will Not Explain Man—Darwin Never Accounted for the Genesis of Man.*—Yet not only are there extensive regions in the doctrine of evolution about which Darwin knew very little, but even as regards the genesis of species his theory was never developed in his own hands so far as to account satisfactorily for the genesis of man. It must be borne in mind that while the natural selection of physical variations will go far toward explaining the characteristics of all the plants and all the beasts in the world, it remains powerless to account for the existence of man. Natural selection of physical variations might go on for a dozen eternities without any other visible result than new

forms of plant and beast in endless and meaningless succession.—FISKE *Through Nature to God,* pt. ii, ch. 5, p. 81. (H. M. & Co., 1900.)

3052. ——— *Wrought by Elemental Forces—Frost Destroys Weak Plants—The Thistle Spreads.*—That which wind and sea are to a sandy beach, the sum of influences, which we term the "conditions of existence," is to living organisms. The weak are sifted out from the strong. A frosty night "selects" the hardy plants in a plantation from among the tender ones as effectually as if it were the wind, and they the sand and pebbles of our illustration; or, on the other hand, as if the intelligence of a gardener had been operative in cutting the weaker organisms down. The thistle, which has spread over the pampas, to the destruction of native plants, has been more effectually "selected" by the unconscious operation of natural conditions than if a thousand agriculturists had spent their time in sowing it.—HUXLEY *Lay Sermons,* serm. 13, p. 317. (G. P. P., 1899.)

3053. SELECTION REQUIRES A HIGHER THAN HUMAN WISDOM—*Constantly Reaches Beyond Man's Intent.*—Hairless dogs have imperfect teeth; long-haired and coarse-haired animals are apt to have, as is asserted, long or many horns; pigeons with feathered feet have skin between their outer toes; pigeons with short beaks have small feet, and those with long beaks large feet. Hence, if man goes on selecting, and thus augmenting, any peculiarity, he will almost certainly modify unintentionally other parts of the structure, owing to the mysterious laws of correlation.—DARWIN *Origin of Species,* ch. 1, p. 11. (Burt.)

3054. SELF, EACH ONE'S SUPREME INTEREST IN—The most natively interesting object to a man is his own personal self and its fortunes. We accordingly see that the moment a thing becomes connected with the fortunes of the self it forthwith becomes an interesting thing. Lend the child his books, pencils, and other apparatus; then give them to him, make them his own, and notice the new light with which they instantly shine in his eyes. He takes a new kind of care of them altogether. In mature life all the drudgery of a man's business or profession, intolerable in itself, is shot through with engrossing significance because he knows it to be associated with his personal fortunes. What more deadly uninteresting object can there be than a railroad time-table? Yet where will you find a more interesting object if you are going on a journey, and by its means can find your train? At such times the time-table will absorb a man's entire attention, its interest being borrowed solely from its relation to his personal life.—JAMES *Talks to Teachers,* ch. 10, p. 95. (H. H. & Co., 1900.)

3055. SELF IN RELATION TO ENVIRONMENT—*Each Person Several Selves.*—Properly speaking, a man has as many social selves as there are individuals who recognize him and carry an image of him in their mind. To wound any one of these his images is to wound him. But as the individuals who carry the images fall naturally into classes, we may practically say that he has as many different social selves as there are distinct groups of persons about whose opinion he cares. He generally shows a different side of himself to each of these different groups. Many a youth who is demure enough before his parents and teachers swears and swaggers like a pirate among his "tough" young friends. We do not show ourselves to our children as to our club companions, to our customers as to the laborers we employ, to our own masters and employers as to our intimate friends. From this there results what practically is a division of the man into several selves, and this may be a discordant splitting, as where one is afraid to let one set of his acquaintances know him as he is elsewhere; or it may be a perfectly harmonious division of labor, as where one tender to his children is stern to the soldiers or prisoners under his command.—JAMES *Psychology,* vol. i, ch. 10, p. 294. (H. H. & Co., 1899.)

3056. SELFISHNESS IN ANIMAL LIFE—*Parasitism a Crime in Nature.*—Among animals these *lazzaroni* are more largely represented still. Almost every animal is a living poorhouse, and harbors one or more species of *Epizoa* or *Entozoa,* supplying them gratis, not only with a permanent home, but with all the necessaries and luxuries of life.

Why does the naturalist think hardly of the parasites? Why does he speak of them as degraded, and despise them as the most ignoble creatures in Nature? . . .

The naturalist's reply to this is brief. Parasitism, he will say, is one of the gravest crimes in Nature. It is a breach of the law of evolution. Thou shalt evolve, thou shalt develop all thy faculties to the full, thou shalt attain to the highest conceivable perfection of thy race—and so perfect thy race—this is the first and greatest commandment of Nature. But the parasite has no thought for its race, or for perfection in any shape or form. It wants two things—food and shelter. How it gets them is of no moment. Each member lives exclusively on its own account an isolated, indolent, selfish, and backsliding life.—DRUMMOND *Natural Law in the Spiritual World,* essay 9, p. 288. (H. Al.)

3057. SELFISHNESS IN DISGUISE OF SPIRITUALITY—*Mohammedan Paradise—True Spiritual Self-seeking.*—Under the head of spiritual self-seeking ought to be included every impulse towards psychic progress, whether intellectual, moral, or spiritual in the narrow sense of the term. It must be

admitted, however, that much that commonly passes for spiritual self-seeking in this narrow sense is only material and social self-seeking beyond the grave. In the Mohammedan desire for paradise and the Christian aspiration not to be damned in hell, the materiality of the goods sought is undisguised. In the more positive and refined view of heaven many of its goods, the fellowship of the saints and of our dead ones, and the presence of God, are but social goods of the most exalted kind. It is only the search of the redeemed inward nature, the spotlessness from sin, whether here or hereafter, that can count as spiritual self-seeking pure and undefiled.—JAMES *Psychology*, vol. i, ch. 10, p. 309. (H. H. & Co., 1899.)

3058. SELFISHNESS ON THE SEA—*Shipwreck for Insurance—Life Less Esteemed than Property.*—There is no doctrine in physics more certainly true than this doctrine in politics—that every practise which the authority of society recognizes or supports has its own train of consequences which, for evil or for good, can be modified or changed in an infinite variety of degrees according as that sanction is given or withheld. . . . Thus, for example, there seems good reason to believe there is a direct relation between the amount of life and property annually sacrificed by shipwreck, and the legislation which recognizes and sanctions insurance to the full amount of the value of ship and cargo. The cause of this is obvious. Care for life is less eager and less wakeful than care for property. This is true even when men are dealing equally with their own property and with their own lives. It is still more true when they are dealing not only with property which is their own, but with lives which belong to others. The inevitable effect of such insurance is therefore to relax the motives of self-interest, which are the strongest incitements to precaution.—ARGYLL *Reign of Law*, ch. 7, p. 217. (Burt.)

3059. SELF-SACRIFICE OF A FLOWER—*Laying Down Life for Offspring—Struggle for the Life of Others.*—Watch this flower at work for a little, and behold a miracle. Instead of struggling for life, it lays down its life. After clothing itself with a beauty which is itself the minister of unselfishness, it droops, it wastes, it lays down its life. The tree still lives; the other leaves are fresh and green; but this life within a life is dead. And why? Because within this death is life. Search among the withered petals, and there, in a cradle of cunning workmanship, are a hidden progeny of clustering seeds — the gift to the future which this dying mother has brought into the world at the cost of leaving it. The food she might have lived upon is given to her children, stored round each tiny embryo with lavish care, so that when they waken into the world the first helplessness of their hunger is met. All the arrangements in plant life which concern the flower, the fruit, and the seed are the creations of the struggle for the life of others.—DRUMMOND *Ascent of Man*, p. 227. (J. P., 1900.)

3060. SENSATION REQUIRES TIME FOR TRANSMISSION—*Whale Not Instantly Aware of Wound.*—People in general imagine, when they think at all about the matter, that an impression upon the nerves —a blow, for example, or the prick of a pin —is felt at the moment it is inflicted. But this is not the case. The seat of sensation being the brain, to it the intelligence of any impression made upon the nerves has to be transmitted before this impression can become manifest as consciousness. The transmission, moreover, requires time, and the consequence is that a wound inflicted on a portion of the body distant from the brain is more tardily appreciated than one inflicted adjacent to the brain. By an extremely ingenious experimental arrangement, Helmholtz has determined the velocity of this nervous transmission, and finds it to be about eighty feet a second, or less than one-thirteenth of the velocity of sound in air. If, therefore, a whale forty feet long were wounded in the tail, it would not be conscious of the injury till half a second after the wound had been inflicted.—TYNDALL *Fragments of Science*, vol. i, ch. 21, p. 439. (A.)

3061. SENSATIONS ACUTE OR MASSIVE—*Touch, Light, Sound—Acuteness vs. Diffusion of Sensation.*—There is an interesting correspondence between the physical and the mental, in regard to a marked distinction among the sensations, in all the senses, between the acute and the voluminous or massive. A sharp prick in the finger, or a hot cinder, yields acute sensations; the contact of the clothing of the entire body, or a warm bath, yields voluminous or massive sensations. Now it is observable that an acute sensation is due to an intense stimulus on a small surface; a massive sensation, to a gentler stimulus over an extended surface. The contrast is noticeable in every one of the senses. A gas flame gives an acute feeling, the diffused sunlight gives a massive feeling. A high note upon the flageolet is acute; a deep bass note on the violoncello or the organ is massive. The sea, the thunder, the shouting of a multitude are voluminous or massive from repetition over a wide area. Taste is acute, digestive feeling is massive. Thus thoroughly does the mere manner of external incidence determine one of the most notable distinctions among our states of feeling.—BAIN *Mind and Body*, ch. 3, p. 11. (Hum., 1880.)

3062. SENSATIONS INCREASED BY ATTENTION—*Unnatural Sensitiveness in Hysteria.*—It is no less certain, however, that the intensity of sensations is greatly affected by the degree in which the recipient mind is directed towards them; and this

may operate in regard either to sensory impressions generally or to those of some particular class. Of the former we have a characteristic example in what is known as the hysterical condition; in which the patient's attention is so fixed upon her own bodily state that the most trivial impressions are magnified into severe pains; while there is often such an extraordinary acuteness to sounds that she overhears a conversation carried on in an undertone in an adjoining room, or (as in a case known to the writer) in a room on the second floor beneath. There is here, doubtless, a peculiar physical susceptibility to nervous impressions, which is to a certain degree remediable by medical treatment; but much depends upon the diversion of the patient's attention from her own fancied ailments, and we here see the importance of the self-determining power of the will, which, if duly exercised, can substitute a healthful direction of the mental activity for the morbid imaginings to which the patient has previously yielded herself.—CARPENTER *Nature and Man*, bk. i, ch. 4, p. 153. (A., 1900.)

3063. SENSATIONS NOT TO BE MEASURED NUMERICALLY—The whole notion of measuring sensations numerically remains in short a mere mathematical speculation about possibilities, which has never been applied to practise.—JAMES *Psychology*, vol. i, ch. 13, p. 539. (H. H. & Co., 1899.)

3064. SENSATIONS OF NORMAL CONSCIOUSNESS TO BE TRUSTED—*Some External Fact Corresponds.*—The physicist, by reducing all external changes to "modes of motion," appears to leave no room in his world-mechanism for the secondary qualities of bodies, such as light and heat, as popularly conceived. Yet, while allowing this, I think we may still regard the attribution of qualities like color to objects as in the main correct and answering to a real fact. When a person says an object is red, he is understood by everybody as affirming something which is true or false, something, therefore, which either involves an external fact or is illusory. It would involve an external fact whenever the particular sensation which he receives is the result of a physical action (ether vibrations of a certain order), which would produce a like sensation in anybody else in the same situation and endowed with the normal retinal sensibility. On the other hand, an illusory attribution of color would imply that there is no corresponding physical agency at work in the case, but that the sensation is connected with exceptional individual conditions, as, for example, altered retinal sensibility.—SULLY *Illusions*, ch. 3, p. 36. (A., 1897.)

3065. SENSE OF BEAUTY, SCIENCE DOES NOT DIMINISH—*Knowledge Not Incompatible with Poetry.*—Does the knowledge of the fact that oxygen has been discovered in the sun tend to diminish by one iota the feeling of joy, the inexpressible sense of delight and wonder, with which we see the red rays rising aslant over the Rigi, and finally bursting into glorious effulgence as peak after peak is tinged with the morning glow? Or when we walk abroad in the full glow of the midday, does the idea of the immensity of heaven's great orb, the knowledge of its distance from us, or the information which details the extent of time occupied in the transit of its light-rays earthward interfere in any sense with our delight in the poetry which has selected astronomy as its theme? Does such knowledge repress what Dr. Shairp would call "the momentary elevation of heart," for which its subject "has no words"? The eye rests on the grateful green of Nature which everywhere meets our gaze, and drinks in the sense of beauty and of this earth's sweet fairness. Shall I the less be filled with joy because I know that the green is the botanist's "chlorophyl," and that but for the verdant hues of plants our world would become a great stagnant pond of foul air?—ANDREW WILSON *Science and Poetry*, p. 8. (Hum., 1888.)

3066. SENSE OF DURATION—*Perception of Empty Time Vast and Dreary—Slow Lapse of a Minute.*—Close your eyes and simply wait to hear somebody tell you that a minute has elapsed. The full length of your leisure with it seems incredible. You engulf yourself into its bowels as into those of that interminable first week of an ocean voyage, and find yourself wondering that history can have overcome many such periods in its course, all because you attend so closely to the mere feeling of the time *per se*, and because your attention to that is susceptible of such fine-grained, successive subdivision. The odiousness of the whole experience comes from its insipidity; for stimulation is the indispensable requisite for pleasure in an experience, and the feeling of bare time is the least stimulating experience we can have.—JAMES *Psychology*, vol. i, ch. 15, p. 626. (H. H. & Co., 1899.)

3067. SENSE OF IGNORANCE A LAW OF MAN'S BEING—*Origin of Curiosity and Wonder—Incentive to Progress.*—It is impossible to mistake, then, the place which is occupied among the unities of Nature by that sense of ignorance which is universal among men. It belongs to the number of those primary mental conditions which impel all living things to do that which it is their special work to do, and in the doing of which the highest law of their being is fulfilled. In the case of the lower animals this law, as to the part they have to play, and the ends they have to serve in the economy of the world, is simple, definite, and always perfectly attained. No advance is with them possible, no capacity

of improvement, no dormant or undeveloped powers leading up to wider and wider spheres of action. With man, on the contrary, the law of his being is a law which demands progress, which endows him with faculties enabling him to make it, and fills him with aspirations which cause him to desire it. Among the lowest savages there is some curiosity and some sense of wonder, else even the rude inventions they have achieved would never have been made, and their degraded superstitions would not have kept their hold. Man's sense of ignorance is one of the greatest of his gifts, for it is the secret of his wish to know. The whole structure and the whole furniture of his mind are adapted to this condition. The highest law of his being is to advance in wisdom and knowledge, and his sense of the presence and of the power of things which he can only partially understand is an abiding witness of this law, and an abiding incentive to its fulfilment.—ARGYLL *Unity of Nature*, ch. 9, p. 189. (Burt.)

3068. SENSE OF PROPERTY MANIFESTED BY DOGS—Dogs seem to have the feeling of the value of their master's personal property, or at least a particular interest in objects which their master uses. A dog left with his master's coat will defend it, tho never taught to do so. I know of a dog accustomed to swim after sticks in the water, but who always refused to dive for stones. Nevertheless, when a fish-basket, which he had never been trained to carry, but merely knew as his master's, fell over, he immediately dived after it and brought it up. Dogs thus discern, at any rate so far as to be able to act, this partial character of being valuable, which lies hidden in certain things.—JAMES *Psychology*, vol. ii, ch. 22, p. 350. (H. H. & Co., 1899.)

3069. SENSE-IMPRESSIONS, COMBINATION AND INTERPRETATION OF—*Attention of Infant Is Automatic.*—In the young child, as among the lower animals, the attention seems purely automatic, being solely determined by the attractiveness of the object: and the diversion of it from one object to another simply depends upon the relative force of the two attractions. It is this automatic fixation of the attention on the sense-impressions received from the external world that enables the infant to effect that marvelous combination of visual and tactile perceptions which guides the whole subsequent interpretation of its phenomena. . . . When an attractive object is presented to it, which it grasps in its little hands, carries to its lips, and holds at different distances, earnestly gazing at it all the while, it is learning a most valuable lesson, and the judicious mother or nurse will not interrupt this process, but will allow the infant to go on with its examination of the object as long as it is so disposed.—CARPENTER *Mental Physiology*, ch. 3, p. 133. (A., 1900.)

3070. SENSE-PERCEPTIONS ACT ONE AT A TIME—*Sight and Hearing among Astronomers.*—Astronomers have long been aware that no human being can hear and see at the same time. If a moving star is being observed through a telescope, and the observer is required to announce, while counting the strokes of a pendulum, at which stroke the star is found at a certain point, he never fails to make a mistake. He generally counts one too many strokes of the pendulum. He sees first and then hears. —PREYER *Ueber Empfindungen (a Lecture).* (Translated for *Scientific Side-Lights.)*

3071. SENSES, ASSUMED "FALLACY" OF—*Intellectual Fallacy by Erroneous Inference.*—Note that in every illusion what is false is what is inferred, not what is immediately given. The "this," if it were felt by itself alone, would be all right; it only becomes misleading by what it suggests. If it is a sensation of sight, it may suggest a tactile object, for example, which later tactile experiences prove to be not there. The so-called "fallacy of the senses," of which the ancient skeptics made so much account, is not fallacy of the senses proper, but rather of the intellect, which interprets wrongly what the senses give.—JAMES *Psychology*, vol. ii, ch. 19, p. 86. (H. H. & Co., 1899.)

3072. SENSES IN CONFLICT—*Vision on Precipice Opposed to Muscular Sense of Equilibrium—Resultant Feeling of Insecurity.*—Thus a person unaccustomed to look down heights feels insecure at the top of a tower or a precipice, altho he knows that his body is properly supported, for the void which he sees below him contradicts (as it were) the muscular sense by which he is made conscious of its due equilibrium. So, again, altho any one can walk along a narrow plank which forms part of the floor of a room, or which is elevated but little above it, without the least difficulty, and even without any consciousness of effort, yet if that plank be laid across a chasm the bottom of which is so far removed from the eye that the visual sense gives no assistance, even those who have braced their nerves against all emotional distraction feel that an effort is requisite to maintain the equilibrium during their passage over it, that effort being aided by the withdrawal of the eyes from the depth below, and the fixation of them on a point beyond, which at the same time helps to give steadiness to the movements and distracts the mind from the sense of its danger.—CARPENTER *Mental Physiology*, bk. i, ch. 5, p. 214. (A., 1900.)

3073. SENSES, JUDGMENT NEEDED TO INTERPRET—The question whether vermilion is really red as we see it, or whether that is only a delusion of our sense, is therefore unmeaning. The sensation of red is the normal reaction from the light reflected from vermilion upon normally constructed

eyes. One who is red-blind would see the vermilion black or a dark grayish yellow; that also is the correct reaction for his peculiar construction of eye. But he ought to be aware that his eyes differ from those of other human beings. In itself the one sensation is neither more correct nor more false than the other, altho the red-seeing are in the majority. In fact, the red color of vermilion only has existence in as far as there are eyes constructed like the majority of eyes. It is absolutely as much a characteristic of vermilion to be black, namely, for the red-blind. The fact is, the light reflected from vermilion is not to be termed red *per se;* it is only red for eyes of a peculiar form. . . . It would seem as if it were unnecessary to mention this, and for that reason we are apt to forget it, and to be deceived into believing that the red is a characteristic belonging to vermilion, or to the light reflected from it, wholly independent of our organs of sight. It is different when we assert that the waves thrown back from vermilion have a certain length. That is an assertion we can make independent of the peculiar nature of our eyes; it is wholly a question of the relations between the substance and the different systems of the waves of ether.—HELMHOLTZ *Handbuch der physiologischen Optik*, p. 589. (Translated for *Scientific Side-Lights.)*

3074. SENSES, KEENNESS OF, AMONG RUDE TRIBES—*Wonderful Skill and Judgment of Savage Hunter.*—The natives of the Brazilian forests, to whom tracking game is the chief business of life, do it with a skill that fills with wonder the white men who have watched them. The Botocudo hunter, gliding stealthily through the underwood, knows every habit and sign of bird and beast; the remains of berries and pods show him what creature has fed there; he knows how high up an armadillo displaces the leaves in passing, and so can distinguish its track from the snake's or tortoise's, and follow it to its burrow by the scratches of its scaly armor on the mud. Even the sense of smell of this savage hunter is keen enough to help him in tracking. Hidden behind the trunk of a tree, he can imitate the cries of birds and beasts to bring them within range of his deadly poisoned arrow, and he will even entice the alligator by making her rough eggs grate together where they lie under leaves on the river-bank. If an ape he has shot high in the boughs of some immense tree remains hanging by its tail, he will go up after it by a hanging creeper where no white man would climb. At last, laden with game and useful forest things, such as palm-fiber to make hammocks, or fruit to brew liquor, he finds his way back to his hut by the sun and the lie of the ground, and the twigs that he bent back for way-marks as he crept through the thicket.—TYLOR *Anthropology*, ch. 9, p. 207. (A., 1899.)

3075. SENSES, RELATIVE ACUTENESS OF—*Keenness of Scent among Arabs.*—It is said that the Arabs of the Sahara can recognize the smell of a fire thirty or forty miles distant.—CARPENTER *Mental Physiology*, bk. i, ch. 3, p. 141. (A., 1900.)

3076. ——— *Keenness of Scent among Indians.*—We are told by Humboldt that the Peruvian Indians in the darkest night can not merely perceive through their scent the approach of a stranger whilst yet far distant, but can say whether he is an Indian, European, or negro.—CARPENTER *Mental Physiology*, bk. i, ch. 3, p. 141. (A., 1900.)

3077. ——— *Progress Accompanied by Decline—Smell of First Importance to Lower Animals—Little Used by Man.*—In general, this lowest, most animal, least intellectual of the sensations [smell] is peculiarly baffling of all attempts to reduce it to terms of science. In the developed and cultivated human species smell has come to be, for the most part, of the nature of an esthetical advantage or affliction, rather than a means of accurate knowledge. But in the lower and less cultivated phases of animal life it, by the prompt and accurate information it furnishes, serves as a most important factor in the preservation, propagation, and evolution of the individual and of the species.—LADD *Psychology*, ch. 6, p. 100. (S., 1899.)

3078. SENSES, TO EXTEND THEIR RANGE ONE OF THE PROBLEMS OF SCIENCE—*Telescope and Microscope.*—One of the problems of science, on which scientific progress mainly depends, is to help the senses of man by carrying them into regions which could never be attained without such help. Thus we arm the eye with the telescope when we want to sound the depths of space, and with the microscope when we want to explore motion and structure in their infinitesimal dimensions.—TYNDALL *Lectures on Light*, lect. 1, p. 12. (A., 1898.)

3079. SENSIBILITY CHANGEABLE—*The World Enduring.*—There are facts which make us believe that our sensibility is altering all the time, so that the same object cannot easily give us the same sensation over again. The eye's sensibility to light is at its maximum when the eye is first exposed, and blunts itself with surprising rapidity. A long night's sleep will make it see things twice as brightly on wakening, as simple rest by closure will make it see them later in the day. We feel things differently according as we are sleepy or awake, hungry or full, fresh or tired; differently at night and in the morning; differently in summer and in winter; and, above all things, differently in childhood, manhood, and old age. Yet we never doubt that our feelings reveal the same world, with the same sensible qualities and the same sensible things occupying it.—JAMES *Psychology*, vol. i, ch. 9, p. 232. (H. H. & Co., 1899.)

3080. SENSITIVENESS OF PLANTS TO LIGHT—*Exactness of Movement.*—In our various experiments we were often struck with the accuracy with which seedlings pointed to a light, altho of small size. To test this, many seedlings of *Phalaris*, which had germinated in darkness in a very narrow box several feet in length, were placed in a darkened room near to and in front of a lamp having a small cylindrical wick. The cotyledons at the two ends and in the central part of the box would therefore have to bend in widely different directions in order to point to the light. After they had become rectangularly bent, a long white thread was stretched by two persons, close over and parallel, first to one and then to another cotyledon, and the thread was found in almost every case actually to intersect the small circular wick of the now extinguished lamp. The deviation from accuracy never exceeded, as far as we could judge, a degree or two.—DARWIN *Power of Movement in Plants*, ch. 9, p. 469. (A., 1900.)

3081. SENSITIVENESS SPECIALIZED—*Leaves of Dionæa Close at Touch of Insect—Wind and Rain Have No Effect.*—Drops of water, or a thin, broken stream, falling from a height on the filaments, did not cause the blades to close, tho these filaments were afterwards proved to be highly sensitive. No doubt, as in the case of *Drosera*, the plant is indifferent to the heaviest shower of rain. Drops of a solution of a half an ounce of sugar to a fluid ounce of water were repeatedly allowed to fall from a height on the filaments, but produced no effect, unless they adhered to them. Again, I blew many times through a fine-pointed tube with my utmost force against the filaments without any effect, such blowing being received with as much indifference as no doubt is a heavy gale of wind. We thus see that the sensitiveness of the filaments is of a specialized nature, being related to a momentary touch rather than to prolonged pressure; and the touch must not be from fluids, such as air or water, but from some solid object.—DARWIN *Insectivorous Plants*, ch. 13, p. 236. (A., 1900.)

3082. SENTIMENT WITHOUT ACTION PERNICIOUS—*Character Hopelessly Enervated.*—No matter how full a reservoir of maxims one may possess, and no matter how good one's sentiments may be, if one have not taken advantage of every concrete opportunity to act, one's character may remain entirely unaffected for the better. . . . A tendency to act only becomes effectively ingrained in us in proportion to the uninterrupted frequency with which the actions actually occur, and the brain "grows" to their use. Every time a resolve or a fine glow of feeling evaporates without bearing practical fruit is worse than a chance lost; it works so as positively to hinder future resolutions and emotions from taking the normal path of discharge. There is no more contemptible type of human character than that of the nerveless sentimentalist and dreamer, who spends his life in a weltering sea of sensibility and emotion, but who never does a manly, concrete deed. Rousseau, inflaming all the mothers of France by his eloquence, to follow Nature and nurse their babies themselves, while he sends his own children to the foundling hospital, is the classical example of what I mean.—JAMES *Psychology*, vol. i, ch. 4, p. 125. (H. H. & Co., 1899.)

3083. SEPARATENESS OF GREAT SUBKINGDOMS OF ANIMALS—*"Missing Links" Not Found—No Transitional Forms Known in Present or Past.*—If I had followed out all these various lines of classification fully I should discover in the end that there was no animal, either recent or fossil, which did not at once fall into one or other of these subkingdoms. In other words, every animal is organized upon one or other of the five or more plans whose existence renders our classification possible. And so definitely and precisely, marked is the structure of each animal that, in the present state of our knowledge, there is not the least evidence to prove that a form, in the slightest degree transitional between any two of the groups *Vertebrata, Annulosa, Mollusca*, and *Cœlenterata*, either exists, or has existed, during that period of the earth's history which is recorded by the geologist.—HUXLEY *Lay Sermons*, vol. vi, p. 103. (A., 1895.)

3084. SERVICE OF AMATEURS—*Schwabe, a German Magistrate, Takes to Counting Sun-spots—Important Law Discovered.*—The sun sometimes has numerous spots on it, and sometimes none at all; but it does not seem to have occurred to any one to see whether they had any regular period for coming or going, till Schwabe, a magistrate in a little German town, who happened to have a small telescope and a good deal of leisure, began for his own amusement to note their number every day. He commenced in 1826, and with German patience observed daily for forty years. He first found that the spots grew more numerous in 1830, when there was no single day without one; then the number declined very rapidly, till in 1833 they were about gone; then they increased in number again till 1838, then again declined; and so on, till it became evident that sun-spots do not come and go by chance, but run through a cycle of growth and disappearance, on the average about once in every eleven years.—LANGLEY *New Astronomy*, ch. 1, p. 77. (H. M. & Co.)

3085. SERVICE OF GREAT TO SMALL—*"Whosoever Will Be Chief among You, Let Him Be Your Servant" (Matt. xxi, 27)—Saturn a Minor Sun to His Satellites.*—We seem compelled, then, to adopt the view that Saturn subserves useful purposes to

the worlds which circle round him. To these he certainly supplies much reflected light, and possibly a considerable proportion of inherent light. He probably warms them in a much greater degree. And it seems no unworthy thought respecting him that even as he sways them by his attractive energy, so he nourishes them as a subordinate sun by the heat with which his great mass is instinct. If our sun, so far surpassing all his dependent worlds in mass, yet acts as their servant in such respects, we may reasonably believe that Saturn and Jupiter act a similar part towards the orbs which circle round them.—PROCTOR *Expanse of Heaven*, p. 103. (L. G. & Co., 1897.)

3086. SERVICE, RECIPROCAL, OF PLANTS AND ANIMALS—Plant life seizes upon its required constituents, and by means of the energy furnished by the sun's rays builds these materials up into its own complex forms. Its many and varied forms fulfil a place in beautifying the world. But their contribution to the economy of Nature is, by means of their products, to supply food for animal life. The products of plant life are chiefly sugar, starch, fat, and proteids. Animal life is not capable of extracting its nutriment from soil, but it must take the more complex foods which have already been built up by vegetable life. Again, the complementary functions of animal and vegetable life are seen in the absorption by plants of one of the waste materials of animals, viz., carbonic acid gas. Plants abstract from this gas carbon for their own use, and return the oxygen to the air, which in turn is of service to animal life.—NEWMAN *Bacteria*, ch. 5, p. 147. (G. P. P., 1899.)

3087. "SETTING" OF THE MEMORY—*Learning in Order to Forget—Religion and Morality May Be Limited to Times and Seasons.*—There is an interesting fact connected with remembering, which, so far as I know, Mr. R. Verdon was the first writer expressly to call attention to. We can set our memory as it were to retain things for a certain time, and then let them depart.

"Individuals often remember clearly and well up to the time when they have to use their knowledge, and then, when it is no longer required, there follows a rapid and extensive decay of the traces. Many schoolboys forget their lessons after they have said them, many barristers forget details got up for a particular case. Thus a boy learns thirty lines of Homer, says them perfectly, and then forgets them so that he could not say five consecutive lines the next morning, and a barrister may be one week learned in the mysteries of making cogwheels, but in the next he may be well acquainted with the anatomy of the ribs instead."

The rationale of this fact is obscure, and the existence of it ought to make us feel how truly subtle are the nervous processes which memory involves.—JAMES *Psychology*, vol. i, ch. 16, p. 685. (H. H. & Co., 1899.)

3088. SEVERITY AND PRIVATION OF THE NORTH—*Mental Triumph a Compensation.*—Many of the enjoyments which Nature affords are denied to the nations of the North. Many constellations and many vegetable forms, including more especially the most beautiful productions of the earth (palms, tree-ferns, bananas, arborescent grasses, and delicately feathered mimosas), remain forever unknown to them; for the puny plants pent up in our hothouses give but a faint idea of the majestic vegetation of the tropics. But the rich development of our language, the glowing fancy of the poet, and the imitative art of the painter, afford us abundant compensation; and enable the imagination to depict in vivid colors the images of an exotic Nature. In the frigid North, amid barren heaths, the solitary student may appropriate all that has been discovered in the most remote regions of the earth, and thus create within himself a world as free and imperishable as the spirit from which it emanates.—HUMBOLDT *Views of Nature*, p. 231. (Bell, 1896.)

3089. SEWING AMONG SAVAGES—*Needles in the Stone Age—New Zealanders Drill Hole in Glass.*—The neatness with which the Hottentots, Eskimos, North-American Indians, etc., are able to sew, is very remarkable, altho awls and sinews would in our hands be but poor substitutes for needles and thread. . . . Some cautious archeologists hesitated to refer the reindeer caves of the Dordogne to the Stone Age, on account of the bone needles and the works of art which are found in them. The eyes of the needles especially, they thought, could only be made with metallic implements. Professor Lartet ingeniously removed these doubts by making a similar needle for himself with the help of a flint: but he might have referred to the fact stated by Cook in his first voyage, that the New Zealanders succeeded in drilling a hole through a piece of glass which he had given them, using for this purpose, as he supposed, a piece of jasper.—AVEBURY *Prehistoric Times*, ch. 15, p. 523. (A., 1900.)

3090. SEWING OF PRIMITIVE WOMAN—Plain sewing among the lowest peoples is an affair of the skin dresser. They do not, as has been said, make cloth in long pieces to be cut up and sewed into garments and other useful things. This being the fact, the best tailors ought to be sought in the arctic regions. And this is true, as any one knows who has examined the garments of caribou skin, of sealskin, of the pelts of the little fur-bearing animals, of the intestines of the larger mammals, wrought by the Siberians and the Eskimo.

Parkas or blouses, trousers or boots, are

cut out with stone or metal knives. The edges of the parts are whipped together with sinews so as to be water-tight. Bits of different colored fur are inserted for ornamentation, and, frequently, to save every scrap, the sempstress will have a hundred pieces of skin in a single garment. Her needle is a tough bit of bone working like an awl, and her sinew is drawn through with a true needle made of bird-bone. Her thimble is a bit of tough seal hide drawn over the end of the forefinger, tho in modern times they imitate in ivory the white woman's thimble.—MASON *Origins of Invention*, ch. 7, p. 248. (S., 1899.)

3091. SEX AND DIVISION OF LABOR—*Woman the Inventor of the Arts of Peace.*—Division of labor began with the invention of fire-making, and it was a division of labor based upon sex. The woman stayed by the fire to keep it alive, while the man went to the field or the forest for game. The world's industrialism and militancy began then and there. Man has been cunning in devising means of killing beast and his fellow man—he has been the inventor in every murderous art. The woman at the fireside became the burden-bearer, the basket-maker, the weaver, potter, agriculturist, domesticator of animals—in a word, the inventor of all the peaceful arts of life.—MASON *Woman's Share in Primitive Culture*, pref., p. 7. (A., 1894.)

3092. SEX BINDS UNITS INTO UNITY—*Separates in Order to Unite—God Setteth the Solitary in Families (Ps. lxviii, 6).*—By a device the most subtle of all that guard the higher evolution of the world—the device of sex—Nature accomplishes this task of throwing irresistible bonds around widely separate things, and establishing such sympathies between them that they must act together or forfeit the very life of their kind. Sex is a paradox; it is that which separates in order to unite. The same mysterious mesh which Nature threw over the two separate palms, she threw over the few and scattered units which were to form the nucleus of mankind.—DRUMMOND *Ascent of Man*, ch. 7, p. 243. (J. P., 1900.)

3093, SEX, DIFFERENTIATION OF, FROM CELL TO SOUL—*Energy, Motion, Activity of Male—Passivity, Gentleness, Repose of Female.*—The predominating note in the male will be energy, motion, activity; while passivity, gentleness, repose, will characterize the female. These words, let it be noticed, psychical tho they seem, are yet here the coinages of physiology. No other terms indeed would describe the difference. Thus Geddes and Thomson: "The female cochineal insect, laden with reserve products in the form of the well-known pigment, spends much of its life like a mere quiescent gall on the cactus plant. The male, on the other hand, in his adult state, is agile, restless, and short-lived. Now this is no mere curiosity of the entomologist, but in reality a vivid emblem of what is an average truth throughout the world of animals—the preponderating passivity of the females, the freedomness and activity of the males." Rolph's words, because he writes neither of men nor of animals, but goes back to the furthest recess of Nature and characterizes the cell itself, are still more significant: "The less nutritive and therefore smaller, hungrier, and more mobile organism is the male; the more nutritive and usually more quiescent is the female."—DRUMMOND *Ascent of Man*, ch. 7, p. 255. (J. P., 1900.)

3094. "SEX OF SOUL"—*Inherent Differences in Mental Activity of Man and Woman.*—It has been affirmed by some philosophers that there is no essential difference between the mind of a woman and that of a man, and that if a girl were subjected to the same education as a boy she would resemble him in tastes, feelings, pursuits, and powers. To my mind it would not be one whit more absurd to affirm that the antlers of the stag, the human beard, and the cock's comb, are effects of education. . . . The physical and mental differences between the sexes intimate themselves very early in life, and declare themselves most distinctly at puberty. . . . While woman preserves her sex, she will necessarily be feebler than man, and, having her special bodily and mental characters, will have to a certain extent her own sphere of activity; where she has become thoroughly masculine in nature, or hermaphrodite in mind—when, in fact, she has pretty well divested herself of her sex—then she may take his ground, and do his work; but she will have lost her feminine attractions, and probably also her chief feminine functions.—MAUDSLEY *Body and Mind*, lect. 1, p. 35. (A., 1898.)

3095. SHADOW SEEMING SUBSTANCE—*A Terrifying Spectacle—Movement of Moon's Shadow across the Earth in Solar Eclipse—Real Confounded with Apparent Motion.*—The reader who has ever ascended to the Superga, at Turin, will recall the magnificent view, and be able to understand the good fortune of an observer (Forbes) who once had the opportunity to witness thence this phenomenon, and under a nearly cloudless sky. "I perceived," he says, "in the southwest a black shadow like that of a storm about to break, which obscured the Alps. It was the lunar shadow coming towards us." And he speaks of the "stupefaction"—it is his word—caused by the spectacle. "I confess," he continues, "it was the most terrifying sight I ever saw. As always happens in the case of sudden, silent, unexpected movements, the spectator confounds real and relative motion. I felt almost giddy for a moment, as tho the massive building under me bowed on the coming eclipse." Another witness, who had been looking at some bright clouds just before, says: "The bright cloud I saw distinctly

put out like a candle. The rapidity of the shadow, and the intensity, produced a feeling that something material was sweeping over the earth at a speed perfectly frightful. I involuntarily listened for the rushing noise of a mighty wind."—LANGLEY *New Astronomy*, ch. 2, p. 38. (H. M. & Co.)

3096. SHELLS, IMPORTANCE OF, IN CHRONOLOGY—*The Medals of Nature.*—In the present state of science, it is chiefly by the aid of shells that we are enabled to arrive at these results [determination of geological time], for of all classes the *Testacea* are the most generally diffused in a fossil state, and may be called the medals principally employed by Nature in recording the chronology of past events.—LYELL *Principles of Geology*, bk. i, ch. 13, p. 183. (A. 1854.)

3097. SHELLS, POMPEIAN, UNCHANGED THROUGH CENTURIES—*Pictures Preserved—Lines Written by Vanished Hands—Enduring Record of the Evanescent.*—The writings scribbled by the soldiers on the walls of their barracks [at Pompeii], and the names of the owners of each house written over the doors, are still perfectly legible. The colors of fresco paintings on the stuccoed walls in the interior of buildings are almost as vivid as if they were just finished. There are public fountains decorated with shells laid out in patterns in the same fashion as those now seen in the town of Naples; and in the room of a painter, who was perhaps a naturalist, a large collection of shells was found, comprising a great variety of Mediterranean species, in as good a state of preservation as if they had remained for the same number of years in a museum. A comparison of these remains with those found so generally in a fossil state would not assist us in obtaining the least insight into the time required to produce a certain degree of decomposition or mineralization; for, altho under favorable circumstances much greater alteration might doubtless have been brought about in a shorter period, yet the example before us shows that an inhumation of seventeen centuries may sometimes effect nothing towards the reduction of shells to the state in which fossils are usually found.—LYELL *Principles of Geology*, bk. ii, ch. 24, p. 392. (A., 1854.)

3098. SHOCK, TRANSMITTED—*Earthquake Heaves Ocean Wave on the Shore.*—Shortly after the shock [of the Chilean earthquake of 1835], a great wave was seen from the distance of three or four miles, approaching in the middle of the bay with a smooth outline; but along the shore it tore up cottages and trees, as it swept onwards with irresistible force. At the head of the bay it broke in a fearful line of white breakers, which rushed up to a height of 23 vertical feet above the highest spring-tides. Their force must have been prodigious, for at the fort a cannon with its carriage, estimated at four tons in weight, was moved 15 feet inwards. A schooner was left in the midst of the ruins, 200 yards from the beach. The first wave was followed by two others, which in their retreat carried away a vast wreck of floating objects. . . . The great wave must have traveled slowly, for the inhabitants of Talcahuano had time to run up the hills behind the town; and some sailors pulled out seaward, trusting successfully to their boat riding securely over the swell, if they could reach it before it broke.—DARWIN *Naturalist's Voyage around the World*, ch. 14, p. 305. (A., 1898.)

3099. ——— ——— *Wide Reach of Earthquake of Lisbon—Felt Over Half the World—Mighty Wave in West Indies.*—The area over which this convulsion [the earthquake of Lisbon] extended is very remarkable. It has been computed, says Humboldt, that on the 1st [of] November, 1755, a portion of the earth's surface four times greater than the extent of Europe was simultaneously shaken. The shock was felt in the Alps and on the coast of Sweden, in small inland lakes on the shores of the Baltic, in Thuringia, and in the flat country of northern Germany. The thermal springs of Toplitz dried up, and again returned, inundating everything with water discolored by ocher. In the islands of Antigua, Barbadoes, and Martinique, in the West Indies, where the tide usually rises little more than two feet, it suddenly rose above twenty feet, the water being discolored and of an inky blackness. The movement was also sensible in the great lakes of Canada. At Algiers and Fez, in the north of Africa, the agitation of the earth was as violent as in Spain and Portugal; and at the distance of eight leagues from Morocco, a village with the inhabitants to the number of about 8,000 or 10,000 persons, are said to have been swallowed up, the earth soon afterwards closing over them.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 495. (A., 1854.)

3100. SHORE, INHOSPITABLE—*Insects Blown Far Out to Sea Off Patagonia.*—When seventeen miles off Cape Corrientes, I had a net overboard to catch pelagic animals. Upon drawing it up, to my surprise I found a considerable number of beetles in it, and altho in the open sea, they did not appear much injured by the salt water. . . . At first I thought that these insects had been blown from the shore: but upon reflecting that out of the eight species four were aquatic, and two others partly so in their habits, it appeared to me most probable that they were floated into the sea by a small stream which drains a lake near Cape Corrientes. On any supposition it is an interesting circumstance to find live insects swimming in the open ocean seventeen miles from the nearest point of land. There are several accounts of insects having been blown off the Patagonian shore. Captain Cook observed it, as did more lately

Captain King in the "Adventure." The cause probably is due to the want of shelter, both of trees and hills, so that an insect on the wing, with an off-shore breeze, would be very apt to be blown out to sea.—DARWIN *Naturalist's Voyage around the World*, ch. 8, p. 160. (A., 1898.)

3101. SHOWER OF VOLCANIC ASHES—*Cattle Overwhelmed in Fiery Deluge—Modern Catastrophe Throws Light on Geologic Past.*—The great crest or cordillera of the Andes is depressed at the Isthmus of Panama to a height of about 1,000 feet, and at the lowest point of separation between the two seas near the Gulf of San Miguel to 150 feet. What some geographers regard as a continuation of that chain in Central America lies to the east of a series of volcanoes, many of which are active in the provinces of Pasto, Popayan, and Guatemala. Coseguina, on the south side of the Gulf of Fonseca, was in eruption in January, 1835, and some of its ashes fell at Truxillo, on the shores of the Gulf of Mexico. What is still more remarkable, on the same day, at Kingston, in Jamaica, the same shower of ashes fell, having been carried by an upper counter-current against the regular east wind which was then blowing. Kingston is about 700 miles distant from Coseguina, and these ashes must have been more than four days in the air, having traveled 170 miles a day. Eight leagues to the southward of the crater the ashes covered the ground to the depth of three yards and a half, destroying the woods and dwellings. Thousands of cattle perished, their bodies being in many instances one mass of scorched flesh. Deer and other wild animals sought the towns for protection; many birds and quadrupeds were found suffocated in the ashes, and the neighboring streams were strewed with dead fish. Such facts throw light on geological monuments, for in the ashes thrown out at remote periods from the volcanoes of Auvergne, now extinct, we find the bones and skeletons of lost species of quadrupeds.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 349. (A., 1854.)

3102. SIGHT AND TOUCH NOT EQUIVALENT—*Recovery from Blindness.*—In regard to our visual conceptions it may be stated with perfect certainty, as the result of very numerous observations made upon persons who have acquired sight for the first time, that these do not serve for the recognition even of those objects with which the individual had become most familiar through the touch, until the two sets of sense-perceptions have been coordinated by experience. . . .

Thus, in a recently recorded case, in which sight was imparted by operation to a young woman who had been blind from birth, but who had nevertheless learned to work well with her needle, when the pair of scissors she had been accustomed to use was placed before her, tho she described their shape, color, and glistening metallic character, she was utterly unable to recognize them as scissors until she put her finger on them, when she at once named them, laughing at her own stupidity (as she called it) in not having made them out before.—CARPENTER *Nature and Man*, lect. 6, p. 201. (A., 1889.)

3103. SIGHT NOT EXPLAINED BY MECHANISM ONLY—*Material Science Cannot Account for Consciousness, Mind, Life.*—[In comparing the camera with the eye, we find a close likeness up to a certain point. Mechanism, physics, and chemistry explain the production of the image in both. But suddenly the likeness disappears. There is something in vision that mechanism, physics, and chemistry cannot explain.] At a certain point molecular and chemical change is replaced by sensation, perception, judgment, thought, emotion. We pass suddenly into another and wholly different world, where reigns an entirely different order of phenomena. The connection between these two orders of phenomena, the material and the mental, altho it is right here in the phenomena of the senses, and altho we bring to bear upon it the microscopic eye of science, is absolutely incomprehensible, and must in the very nature of things always remain so. Certain vibrations of the molecules of the brain, certain oxidations, with the formation of carbonic acid, water, and urea, are on the one side, and there appear on the other sensations, consciousness, thoughts, desires, volitions. There are, as it were, two sheets of blotting-paper pasted together: the one is the brain, the other is the mind. Certain ink-scratches and ink-blotchings, utterly meaningless on the one, soak through and appear on the other as intelligible writing. But how or why we know not, and can never hope even to guess. Certain physical phenomena—molecular vibrations, decompositions, and recompositions—occur, and there emerge, how we know not, psychical phenomena—thoughts, emotions, etc. Aladdin's lamp is rubbed—physical phenomenon—and the genie appears—psychical phenomenon.—LE COMTE *Sight*, ch. 3, p. 167. (A., 1897.)

3104. SIGNIFICATION OF LANGUAGE LEARNED BY DEAF-MUTE—*Dr. Howe and Laura Bridgman.*—Dr. Howe began to teach Laura Bridgman by gumming raised letters on various familiar articles. The child was taught by mere contiguity to pick out a certain number of particular articles when made to feel the letters. But this was merely a collection of particular signs, out of the mass of which the general purpose of signification had not yet been extracted by the child's mind. Dr. Howe compares his situation at this moment to that of one lowering a line to the bottom of the deep sea in which Laura's soul lay, and waiting until she should spontaneously take hold of it and be raised into the light. The moment came, "accompanied by a radi-

ant flash of intelligence and glow of joy"; she seemed suddenly to become aware of the general purpose embedded in the different details of all these signs, and from that moment her education went on with extreme rapidity.—JAMES *Psychology*, vol. ii, ch. 22, p. 358. (H. H. & Co., 1899.)

3105. SILENCE IN VACUUM—*Sound Demands a Medium.*—Sound cannot be transmitted through a vacuum, as shown by the following familiar experiment made by a philosopher named Hawksbee as far back as 1705. Place a bell that is operated by a clock-work inside of the receiver of an air-pump. This receiver is a large bell glass, ground to make an air-tight fit on the bed-plate of the air-pump. Suspend the bell inside the receiver, by some kind of cord that will not transmit sound, and then set it to ringing. At first it will ring as loudly as tho it were in the open air. Now, work the pump and exhaust the air. The sound will grow fainter until a nearly perfect vacuum is obtained, when the sound will cease, altho the hammer is still striking the bell the same as at first. Now let the air in and the ringing is heard again.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 6, p. 62. (F. H. & H., 1900.)

3106. SILENCE PRODUCED BY INTERFERING SOUNDS—*Analogies of Sound and Light—Darkness Produced by Adding Light to Light.*—Thomas Young's fundamental discovery in optics was that the principle of interference was applicable to light. Long prior to his time an Italian philosopher, Grimaldi, had stated that under certain circumstances two thin beams of light, each of which, acting singly, produced a luminous spot upon a white wall, when caused to act together, partially quenched each other and darkened the spot. This was a statement of fundamental significance, but it required the discoveries and the genius of Young to give it meaning. How he did so will gradually become clear to you. You know that air is compressible; that by pressure it can be rendered more dense, and that by dilation it can be rendered more rare. Properly agitated, a tuning-fork now sounds in a manner audible to you all, and most of you know that the air through which the sound is passing is parceled out into spaces in which the air is condensed, followed by other spaces in which the air is rarefied. These condensations and rarefactions constitute what we call waves of sound. You can imagine the air of a room traversed by a series of such waves, and you can imagine a second series sent through the same air, and so related to the first that condensation coincides with condensation and rarefaction with rarefaction. The consequence of this coincidence would be a louder sound than that produced by either system of waves taken singly. But you can also imagine a state of things where the condensations of the one system fall upon the rarefactions of the other system. In this case the two systems would completely neutralize each other. Each of them taken singly produces sound; both of them taken together produce no sound. Thus, by adding sound to sound we produce silence, as Grimaldi in his experiment produced darkness by adding light to light.—TYNDALL *Lectures on Light*, lect. 2, p. 57. (A., 1898.)

3107. SIMILARITY, ASSOCIATION BY—*At the Foundation of Reasoning.*—After the few most powerful practical and esthetic interests, our chief help towards noticing those special characters of phenomena which, when once possessed and named, are used as reasons, class names, essences, or middle terms, is this association by similarity. Without it, indeed, the deliberate procedure of the scientific man would be impossible; he could never collect his analogous instances. But it operates of itself in highly gifted minds without any deliberation, spontaneously collecting analogous instances, uniting in a moment what in Nature the whole breadth of space and time keeps separate, and so permitting a perception of identical points in the midst of different circumstances, which minds governed wholly by the law of contiguity could never begin to attain.—JAMES *Psychology*, vol. ii, ch. 22, p. 347. (H. H. & Co., 1899.)

3108. SIMILARITY OF INVENTIONS—*How Far Denoting Unity of Race.*—It is agreed, then, by all that certain kinds of similarity may exist in regions wide apart independently when the occasion arises and the environment permits. It is also admitted that things may be so similar as to allow no doubt that they were created under the inspiration of the same teachers. There is, then, a criterion, a boundary line, not definitely fixed, perhaps, but a fence between those so-called similarities that arise independently and those which show acculturation of some kind. This fence must be largely psychological.

The question, I repeat, is not one of origins at all, but one of the number, kinds, and degrees of similarities in the artificialities of life. For example, the invention of the canoe is a natural, human process: the bark canoe is environmental, the birch-bark canoe is culture-historical. But what should we say of the Amur and the Columbia River types, each pointed beneath the water like a monitor and unlike any other species? Surely these must have some kind of acculturation. Now, if it be found that the Columbia stock and the Amur people have also the same name for their pointed canoes, and a multitude of other coordinated likenesses, then kinship of blood or nationality is proclaimed.—MASON *Similarities in Culture*, from the *American Anthropologist*, vol. viii, p. 115.

3109. SIMILARITY THE FOUNDATION OF SCIENCE, AS OF WIT—*Genius Involves Hard Work.*—The first discovery of

a new law is the discovery of a similarity which has hitherto been concealed in the course of natural processes. It is a manifestation of that which our forefathers in a serious sense described as "wit"; it is of the same quality as the highest performances of artistic perception in the discovery of new types of expression. It is something which cannot be forced, and which cannot be acquired by any known method. Hence all those aspire after it who wish to pass as the favored children of genius. It seems, too, so easy, so free from trouble, to get by sudden mental flashes an unattainable advantage over our contemporaries. The true artist and the true inquirer know that great works can only be produced by hard work.—HELMHOLTZ *Popular Lectures,* lect. 5, p. 227. (L. G. & Co., 1898.)

3110. SIMPLICITY OF METHOD—*Opens Way to Marvelous Result—Magnetism Converted into Electric Light—Faraday's Experiment.*—In the fall of 1831, Professor Faraday announced that from a magnet he had obtained electricity. On the 8th of February, 1832, he entered in his notebook: "This evening, at Woolwich, experimented with magnet, and for the first time got the magnetic spark myself. . . ."

Next day he repeated this experiment, and then, as was his habit, invited some of his friends to see the new light. He had a piece of soft iron, surrounded by coils of wire insulated with calico and tied by common string. When he touched the pole of a magnet with the soft iron, the ends of the coil, as he says, opened a little, and a spark passed between them. An electrical current had been caused in the coil.—PARK BENJAMIN *Age of Electricity,* ch. 7, p. 88. (S., 1897.)

3111. SIMPLICITY OF SCIENTIFIC DISCOVERY—*Forms of Leaves Modified by Environment.*—In the year 1851, during a country ramble in which the structures of plants had been a topic of conversation with a friend—Mr. G. H. Lewes—I happened to pick up the leaf of a buttercup, and, drawing it by its footstalk through my fingers so as to thrust together its deeply cleft divisions, observed that its palmate and almost radial form was changed into a bilateral one; and that were the divisions to grow together in this new position, an ordinary bilateral leaf would result. Joining this observation with the familiar fact that leaves, in common with the larger members of plants, habitually turn themselves to the light, it occurred to me that a natural change in the circumstances of the leaf might readily cause such a modification of form as that which I had produced artificially. If, as they often do with plants, soil and climate were greatly to change the habit of the buttercup, making it branched and shrublike, and if these palmate leaves were thus much overshadowed by one another, would not the inner segments of the leaves grow towards the periphery of the plant where the light was greatest, and so change the palmate form into a more decidedly bilateral form? Immediately I began to look round for evidence of the relation between the forms of leaves and the general characters of the plants they belong to, and soon found some signs of connection. Certain anomalies, or seeming anomalies, however, prevented me from then pursuing the inquiry much further. But consideration cleared up these difficulties; and the idea afterwards widened into the general doctrine [of morphological development] here elaborated.—SPENCER *Biology,* pt. iv, ch. 9, p. 160. (A., 1900.)

3112. ——— ——— *The Counting of Sun-spots Reveals Solar Period.*—Periodicity of the manifestation of solar activity is a fact now proved with the most unquestionable certainty. It was discovered by him who first thought of counting the spots on the sun. What a beautiful lesson for astronomical amateurs! How discoveries may be thus made by simple curiosity or by perseverance! What could apparently be more childish than the idea of amusing oneself by counting every day the spots on the sun? Nevertheless, the name of Schwabe will remain inscribed in the annals of astronomy for having thus discovered this mysterious period of eleven years in the variation of the solar spots.—FLAMMARION *Popular Astronomy,* bk. iii, ch. 5, p. 284. (A.)

3113. SINGING A PLEASURE TO SONG-BIRDS—*Brilliancy of Color Does Not Accompany Musical Power.*—The act of singing is evidently a pleasurable one; and it probably serves as an outlet for superabundant nervous energy and excitement, just as dancing, singing, and field sports do with us. It is suggestive of this view that the exercise of the vocal power seems to be complementary to the development of accessory plumes and ornaments, all our finest singing birds being plainly colored, and with no crests, neck or tail plumes to display, while the gorgeously ornamented birds of the tropics have no song, and those which expend much energy in display of plumage, as the turkey, peacock, birds of paradise, and humming-birds, have comparatively an insignificant development of voice.—WALLACE *Darwinism,* ch. 10, p. 192. (Hum.)

3114. SINGLENESS OF THEORY SOUGHT IN MEDICINE—*All Diseases To Be Referred to One Cause—"The Four Cardinal Fluids."*—What was not right was the [old] delusion that it was more scientific to refer all diseases to one kind of explanation than to several. What was called the "solidar pathology" wanted to deduce everything from the altered mechanism of the solid parts, especially from their altered tension; from the *strictum* and *laxum,* from tone and want of tone, and afterwards from

strained or relaxed nerves and from obstructions in the vessels. Humoral pathology was only acquainted with alterations in mixture. The four cardinal fluids, representatives of the classical four elements, blood, phlegm, black and yellow gall; with others, the acrimonies or dyscrasies, which had to be expelled by sweating and purging, . . . all these were elements of their chemistry.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 210. (L. G. & Co., 1898.)

3115. SIZE RELATIVE—*Difference in Point of View—Microscopic Objects Regarded as Immense.*—To two men, one educated in the school of the senses, having mainly occupied himself with observation; the other educated in the school of imagination as well, and exercised in the conceptions of atoms and molecules to which we have so frequently referred, a bit of matter, say $\frac{1}{5000}$ of an inch in diameter, will present itself differently. The one descends to it from his molar heights, the other climbs to it from his molecular lowlands. To the one it appears small, to the other large. So, also, as regards the appreciation of the most minute forms of life revealed by the microscope. To one of the men these naturally appear conterminous with the ultimate particles of matter; there is but a step from the atom to the organism. The other discerns numberless organic gradations between both. Compared with his atoms, the smallest vibrios and bacteria of the microscopic field are as behemoth and leviathan.—TYNDALL *Fragments of Science*, vol. ii, ch. 8, p. 124. (A., 1897.)

3116. ——— ——— *Dimensions of Sun-spots—One Spot Might Engulf the Earth.*—The dimensions of sun-spots are sometimes enormous. Many groups have been observed covering areas of more than one hundred thousand miles square, and single spots have been known to measure forty or fifty thousand miles in diameter, the central umbra alone being twenty-five or thirty thousand miles across. A spot, however, measuring thirty thousand miles over all, would be considered large rather than small. —YOUNG *The Sun*, ch. 4, p. 126. (A., 1898.)

3117. SKELETON ADORNED WITH JEWELS—*Mother and Babe Perish Together—Remains at Pompeii.*—A very small number of skeletons have been discovered in either city [Herculaneum or Pompeii]; and it is clear that most of the inhabitants not only found time to escape, but also to carry with them the principal part of their valuable effects. In the barracks at Pompeii were the skeletons of two soldiers chained to the stocks, and in the vaults of a country house in the suburbs were the skeletons of seventeen persons, who appear to have fled there to escape from the shower of ashes. They were found enclosed in an indurated tuff, and in this matrix was preserved a perfect cast of a woman, perhaps the mistress of the house, with an infant in her arms. Altho her form was imprinted on the rock, nothing but the bones remained. To these a chain of gold was suspended, and on the fingers of the skeletons were rings with jewels. Against the sides of the same vault was ranged a long line of earthen amphoræ. —LYELL *Principles of Geology*, bk. ii, ch. 24, p. 391. (A., 1854.)

3118. SKEPTICISM, PSYCHOLOGICAL, CONTRADICTS ITSELF—*Duty and Morality Remain—Truth of Skeptical Denial Assumed.*—If you repeat again and again that there are only relative laws, no absolute truth and beauty and morality, that they are changing products of the outer conditions without binding power, you contradict yourself by the assertion. Do you not demand already for your skeptical denial that at least this denial itself is an absolute truth? And when you discuss it, and stand for your conviction that there is no morality, does not this involve your acknowledgment of the moral law to stand for one's conviction? . . . Psychological skepticism contradicts itself by its pretensions; there is a truth, a beauty, a morality, which is independent of psychological conditions.—MÜNSTERBERG *Psychology and Life*, p. 17. (H. M. & Co., 1899.)

3119. SKETCH OF CREATIVE PURPOSE IN EARLY FOSSILS—These early types seem to sketch in broad, general characters the creative purpose, and to include in the first average expression of the plan all its structural possibilities. The crinoid forms include the thought of the modern starfishes and sea-urchins; the simple chambered shells of the Silurian anticipate the more complicated structure of the later ones; the trilobites give the most comprehensive expression of the articulate type, while the early fishes not only prophesy the reptiles which are to come, but also hint at birds and even at mammalia by their embryonic development and their mode of reproduction. —AGASSIZ *Geological Sketches*, ser. i, ch. 2, p. 58. (H. M. & Co., 1896.)

3120. SKILL OF PRIMITIVE MAN IN STONE-WORKING—*Difficult for Civilized Man To Attain.*—Easy as it may seem to make such flakes as these [prehistoric flint specimens], a little practise will convince any one who attempts to do so, that a certain knack is required; and a gun-flint maker at Brandon told me that it took him two years to acquire the art. It is also necessary to be careful in selecting the flint. It is therefore evident that these flakes, simple as they may appear, are always the work of man. To make one, the flint must be held firmly, and then a considerable force must be applied, either by pressure or by blows repeated three or four times, but at least three, and given in certain slightly different directions, with a certain definite force; conditions which could scarcely occur

by accident; so that a flint flake, simple as it may seem to the untrained eye, is to the antiquary as sure a trace of man as the footprint in the sand was to Robinson Crusoe.—AVEBURY *Prehistoric Times*, ch. 4, p. 83. (A., 1900.)

3121. SKINS AS CLOTHING—*Woman the Skin Dresser of Ancient Times.*—If aught in the heavens above, or on the earth beneath, or in the waters wore a skin, savage women were found on examination to have had a name for it, and to have succeeded in turning it into its primitive use for human clothing, and to have invented new uses undreamed of by its original owner. . . . As any taxidermist, or farmer's boy, for that matter, knows, there are hosts of birds and fish and small mammals whose hides need only to be drawn off and dried wrong side out in the sun to be completely cured. The furrier has his way of keeping out the destructive insects, and the taxidermist knows the virtues of arsenical soap; but away on the boundaries of time or civilization the harmonies of Nature had not been so much disturbed, hence there was not such trouble with insect pests. Furthermore, the garment or what-not was in daily use until it was worn out, so there was poor chance for moths or dermestids.—MASON *Woman's Share in Primitive Culture*, ch. 4, p. 71. (A., 1894.)

3122. SKULL, PREHISTORIC, MIGHT HAVE BELONGED TO A PHILOSOPHER—*No Mark of Degradation in Engis Skull.*—Taking the evidence as it stands, and turning first to the Engis skull, I confess I can find no character in the remains of that cranium which, if it were a recent skull, would give any trustworthy clue as to the race to which it might appertain. Its contours and measurements agree very well with those of some Australian skulls which I have examined, and especially has it a tendency toward that occipital flattening, to the great extent of which in some Australian skulls I have alluded. But all Australian skulls do not present this flattening, and the superciliary ridge of the Engis skull is quite unlike that of the typical Australians. On the other hand, its measurements agree equally well with those of some European skulls. And assuredly there is no mark of degradation about any part of its structure. It is, in fact, a fair average human skull, which might have belonged to a philosopher or might have contained the thoughtless brains of a savage.—HUXLEY *Man's Place in Nature*, p. 253. (Hum.)

3123. SKY, ARTIFICIAL—*Composite Particles Too Small for Microscope—Infinitesimal Minuteness.*—Into an experimental tube I introduce a new vapor, . . . and add to it air which has been permitted to bubble through dilute hydrochloric acid. On permitting the electric beam to play upon the mixture, for some time nothing is seen. The chemical action is doubtless progressing, and condensation is going on; but the condensing molecules have not yet coalesced to particles sufficiently large to scatter sensibly the waves of light. . . . The particles here generated are at first so small that their diameters do not probably exceed a millionth of an inch; while to form each of these particles whole crowds of molecules are probably aggregated. Helped by such considerations, our intellectual vision plunges more profoundly into atomic Nature, and shows us, among other things, how far we are from the realization of Newton's hope that the molecules might one day be seen by means of microscopes. While I am speaking, you observe this delicate blue color forming and strengthening within the experimental tube. No sky-blue could exceed it in richness and purity; but the particles which produce this color lie wholly beyond our microscopic range. A uniform color is here developed, which has as little breach of continuity—which yields as little evidence of the individual particles concerned in its production—as that yielded by a body whose color is due to true molecular absorption. This blue is at first as deep and dark as the sky seen from the highest Alpine peaks, and for the same reason. But it grows gradually brighter, still maintaining its blueness, until at length a whitish tinge mingles with the pure azure, announcing that the particles are now no longer of that infinitesimal size which scatters only the shortest waves.—TYNDALL *Heat a Mode of Motion*, lect. 16, p. 490. (A., 1900.)

3124. SKY, CLOUDLESS, CONTAINS DUST-PARTICLES—*Matter from All Lands and from Celestial Spaces.*—Something, then, in a cloudless sky still exists to reflect the rays toward us, and this something is made up of separately invisible specks of dust and vapor, but very largely of actual dust, which probably forms the nucleus of each mist-particle. That discrete matter of some kind exists here has long been recognized from the phenomena of twilight; but it is, I think, only recently that we are coming to admit that a shell of actual solid particles in the form of dust probably encloses the whole globe, up to far above the highest clouds.

In 1881 the writer had occasion to conduct a scientific expedition to the highest point in the territories of the United States, on one of the summits of the Sierra Nevadas of Southern California, which rise even above the Rocky Mountains. . . . Yet even above here on the highest peak, where we felt as if standing on the roof of the continent and elevated into the great aerial currents of the globe, the telescope showed particles of dust in the air, which the geologists deemed to have probably formed part of the soil of China and to have been borne across the Pacific, but which also, as we

shall see later, may owe something to the mysterious source of the phenomena [meteors] already alluded to.—LANGLEY *The New Astronomy*, ch. 6, p. 179. (H. M. & Co., 1896.)

3125. SKY COMBINES ALL COLORS—*Blue Not Sole, but Predominant—Smallest Particles Reflect Smallest Waves.*—In the case of water, for example, a pebble will intercept and reflect a larger fractional part of a ripple than of a larger wave. We have now to imagine light-undulations of different dimensions, but all exceedingly minute, passing through air laden with extremely small particles. It is plain that such particles, tho scattering portions of all the waves, will exert their most conspicuous action upon the smallest ones; and that the color-sensation answering to the smallest waves—in other words, the color blue—will be predominant in the scattered light. This harmonizes perfectly with what we observe in the firmament. The sky is blue, but the blue is not pure. On looking at the sky through a spectroscope we observe all the colors of the spectrum; blue is merely the predominant color.—TYNDALL *Fragments of Science*, vol. i, ch. 5, p. 138. (A., 1897.)

3126. SLAVERY DEGRADES THE MASTERS—*Slave-making Ants Powerless to Help or Feed Themselves.*—*Polyergus rufescens* present a striking lesson of the degrading tendency of slavery, for these ants have become entirely dependent on their slaves. Even their bodily structure has undergone a change; the mandibles have lost their teeth, and have become mere nippers, deadly weapons, indeed, but useless except in war. They have lost the greater part of their instincts: their art, that is, the power of building; their domestic habits, for they show no care for their own young, all this being done by the slaves; their industry—they take no part in providing the daily supplies; if the colony changes the situation of its nest, the masters are all carried by the slaves on their backs to the new one; nay, they have even lost the habit of feeding. Huber placed thirty of them with some larvæ and pupæ and a supply of honey in a box. "At first," he says, "they appeared to pay some little attention to the larvæ; they carried them here and there, but presently replaced them. More than one-half of the Amazons died of hunger in less than two days. They had not even traced out a dwelling, and the few ants still in existence were languid and without strength. I commiserated their condition, and gave them one of their black companions. This individual, unassisted, established order, formed a chamber in the earth, gathered together the larvæ, extricated several young ants that were ready to quit the condition of pupæ, and preserved the life of the remaining Amazons."—AVEBURY *Ants, Bees, and Wasps*, ch. 4, p. 82. (A., 1900.)

3127. "SLEEP" OF PLANTS—*Purpose Not the Same as in Sleep of Animals.*—The so-called sleep of leaves is so conspicuous a phenomenon that it was observed as early as the time of Pliny; and since Linnæus published his famous essay, "Somnus Plantarum," it has been the subject of several memoirs. Many flowers close at night, and these are likewise said to sleep; but we are not here concerned with their movements, for altho effected by the same mechanism as in the case of young leaves, namely, unequal growth on the opposite sides (as first proved by Pfeffer), yet they differ essentially in being excited chiefly by changes of temperature instead of light, and in being effected, as far as we can judge, for a different purpose. Hardly any one supposes that there is any real analogy between the sleep of animals and that of plants, whether of leaves or flowers.—DARWIN *Power of Movement in Plants*, ch. 6, p. 283. (A., 1900.)

3128. SLEEP THE REPOSE OF THE BRAIN—*Rest of Voluntary and Involuntary Muscles Compared.*—All parts of the body which are the seat of active change require periods of rest. The alternation of work and rest is a necessary condition of their maintenance and of the healthy performance of their functions. These alternating periods, however, differ much in duration in different cases; but, for any individual instance, they preserve a general and rather close uniformity. Thus, as before mentioned, the periods of rest and work, in the case of the heart, occupy, each of them, about half a second; in the case of the ordinary respiratory muscles the periods are about four or five times as long. In many cases, again (as of the voluntary muscles during violent exercise), while the periods during active exertion alternate very frequently, yet the expenditure goes far ahead of the repair, and to compensate for this an after-repose of some hours becomes necessary, the rhythm being less perfect as to time than in the case of the muscles concerned in circulation and respiration.

Obviously, it would be impossible that in the case of the brain there should be short periods of activity and repose, or in other words, of consciousness and unconsciousness. The repose must occur at long intervals, and it must therefore be proportionately long. Hence the necessity for that condition which we call "sleep," a condition which, seeming at first sight exceptional, is only an unusually perfect example of what occurs, at varying intervals, in every actively working portion of our bodies.—BAKER *Handbook of Physiology*, vol. ii, ch. 18, p. 135. (W. W., 1885.)

3129. ——— ——— *Withdrawal of Blood Leaving Brain Anemic—Parallel of Swooning.*—A temporary abrogation of the functions of the cerebrum imitating sleep may occur, in the case of injury or disease,

as the consequence of two apparently widely different conditions. Insensibility is equally produced by a deficient and an excessive quantity of blood within the cranium (coma); but it was once supposed that the latter offered the truest analogy to the normal condition of the brain in sleep, and in the absence of any proof to the contrary the brain was said to be during sleep congested. Direct experimental inquiry has led, however, to the opposite conclusion.

By exposing, at a circumscribed spot, the surface of the brain of living animals, and protecting the exposed part by a watch-glass, Durham was able to prove that the brain becomes visibly paler (anemic) during sleep; and the anemia of the optic disk during sleep, observed by Hughlings Jackson, may be taken as a strong confirmation, by analogy, of the same fact.—BAKER *Handbook of Physiology*, vol. ii, ch. 18, p. 135. (W. W., 1885.)

3130. SLOWNESS OF ACTION OF TITANIC FORCES—*Gradual Growth of Continents—Earth Behaving Now Substantially as in Former Ages.*—When geologists began to unravel the earth's history, they were naturally led to suppose that the present was a time of unusual repose, the earlier ages having been periods when the forces which affect the earth were in a state of often recurring and violent activity. As long as the observer was compelled to conceive the construction of the world to have been accomplished in a few thousand years, it was inevitable that he should assume a certain violence in the development of the earth's features. Gradually the fancy for startling theories concerning the past history of this sphere which led to these views has, under the influence of better knowledge, been put aside. Geologists now believe that the continents have grown slowly from the seas, and that the mountains, with all their exhibitions of titanic energy, have likewise gradually come to their present state—in a word, that the crust of the earth behaves at the present day substantially as it has acted at all stages in its history, since life came upon it.—SHALER *Nature and Man in America*, ch. 4, p. 131. (S., 1899.)

3131. SMOKE AS A PRESERVATIVE OF FOOD AMONG SAVAGES—Smoke as a preservative of food is a very early invention. No sight is more common in a savage hut than that of a frame suspended over the fire in the center of the cabin for holding fish or meat to be dried out and smoked for future use. It will be readily seen that this was a potent factor in the increase of longevity, not only securing provisions for time of famine, but eliminating a portion of the noxious creatures that prey on subsistence and shorten life.—MASON *Origins of Invention*, ch. 3, p. 105. (S., 1899.)

3132. SNOW HOLDS WATER IN STORE—*Gradual Distribution in Place of Torrents and Floods.*—In mountainous regions it [snow] accumulates moisture that might otherwise have fallen in repeated torrents, tearing the soil from the mountainsides, inundating the valleys, and spending almost all its energy in destruction, and allows that moisture to be stored up for future use, to feed the streams that water the valleys, and to keep them filled with comparative regularity and constancy. In level countries it performs a similar service in another way, keeping the underlying ground refreshed with water that trickles from the snow as it is slowly melted from underneath by the warmth of the earth itself.—CHISHOLM *Nature-Studies*, p. 31. (Hum., 1888.)

3133. SNOW-CRYSTALS ON MOUNTAINTOPS—*Prisms Like Delicate Needles—Type Preserved through All Change.*—On the tops of mountains and in high latitudes, where the snow falls through the air at a very low temperature, the particles may take the form of extremely delicate needles, or may seem to resemble a fine white dust. But these needles, on a close examination, are found to be minute six-sided prisms, the sides of which are inclined to one another at precisely the same angle as would be formed by two lines joining the ends of three adjoining rays in an ordinary snowflake; and the particles of snow-dust may generally be found on examination with a lens to show at least the minute beginnings of rays such as are seen in more elaborate forms. Some of the beauty may be wanting, but the exquisite mathematical regularity is always there. It is this regularity which makes the form of a snowflake more wonderful, as we have said, than the form of the rain-drop. Wonderful it will always remain, even tho science should ultimately be able to explain the general laws under which particles of water assume this form in freezing.—CHISHOLM *Nature-Studies*, p. 26. (Hum., 1889.)

3134. SOAP-BUBBLE A UTENSIL OF SCIENCE—*Prismatic Colors Shown in Films.*—Any film whatever will produce these colors. The film of air between two plates of glass squeezed together exhibits, as shown by Hooke, rich fringes of color. . . . Nor is even air necessary; the rupture of optical continuity suffices. Smite with an ax the black, transparent ice—black because it is pure and of great depth—under the moraine of a glacier; you readily produce in the interior flaws which no air can reach, and from these flaws the colors of thin plates sometimes break like fire. But the source of most historic interest is, as already stated, the soap-bubble. With one of those mixtures employed by the eminent blind philosopher Plateau in his researches on the cohesion figures of thin films, we obtain in still air a bubble ten or twelve inches

in diameter. You may look at the bubble itself, or you may look at its projection upon the screen; rich colors arranged in zones are, in both cases, exhibited. Rendering the beam parallel, and permitting it to impinge upon the sides, bottom, and top of the bubble, gorgeous fans of color overspread the screen, rotating as the beam is carried round the circumference of the bubble. By this experiment the internal motions of the film are also strikingly displayed. [See COLORS OF THIN PLATES; FILMS; LIGHT.]—TYNDALL *Lectures on Light*, lect. 2, p. 67. (A., 1898.)

3135. SOCIABILITY A PROTECTION—*Gregarious Mammals Dominate the World—Cooperation and Sympathy Begin in the Lower Realm.*—Run over the names of the commoner or more dominant mammals, and it will be found that they are those which have at least a measure of sociability. The cat tribe excepted, nearly all live together in herds or troops—the elephant, for instance, the buffalo, deer, antelope, wild goat, sheep, wolf, jackal, reindeer, hippopotamus, zebra, hyena, and seal. These are mammals, observe—an association of sociability in its highest developments with reproductive specialization. Cases undoubtedly exist where the sociability may not be referable primarily to this function; but in most the chief cooperations are centered in love. So advantageous are all forms of mutual service that the question may be fairly asked whether after all cooperation and sympathy—at first instinctive, afterwards reasoned—are not the greatest facts even in organic Nature?—DRUMMOND *Ascent of Man*, ch. 7, p. 238. (J. P., 1900.)

3136. SOCIETY, MAN DEPENDENT ON—Man in himself is a defenseless, helpless creature. No other animal continues so long in a state of infancy, no other exists so long before obtaining its teeth, no other so long before it is able to stand, no other arrives so late at puberty. Even his greatest advantages, reason and speech, are but germs that develop not spontaneously, but only by means of external assistance, cultivation, and education. This necessity of assistance and his numerous urgent wants prove the natural destination of man for social connections.—BLUMENBACH *Manual of Natural History*, § 4, p. 35.

3137. SOIL PILED UP BY WORMS—*Materials Digested into Fertility.*—Worms have played a more important part in the history of the world than most persons would at first suppose. In almost all humid countries they are extraordinarily numerous, and for their size possess great muscular power. In many parts of England a weight of more than ten tons (10,516 kilograms) of dry earth annually passes through their bodies and is brought to the surface on each acre of land; so that the whole superficial bed of vegetable mold passes through their bodies in the course of every few years. From the collapsing of the old burrows the mold is in constant tho slow movement, and the particles composing it are thus rubbed together. By these means fresh surfaces are continually exposed to the action of the carbonic acid in the soil, and of the humus acids which appear to be still more efficient in the decomposition of rocks. The generation of the humus acids is probably hastened during the digestion of the many half-decayed leaves which worms consume. Thus the particles of earth, forming the superficial mold, are subjected to conditions eminently favorable for their decomposition and disintegration. Moreover, the particles of the softer rocks suffer some amount of mechanical trituration in the muscular gizzards of worms, in which small stones serve as mill-stones.—DARWIN *Formation of Vegetable Mould*, ch. 7, p. 89. (Hum., 1887.)

3138. SOILS, EXHAUSTION OF—*Rotation of Crops Scientific—Practise in Advance of Science.*—We know that a virgin soil cropped for several years loses its productive powers, and without artificial aid becomes unfertile. For example, through this exhaustion forty bushels of wheat per acre have dwindled to seven. Rotation of crops is an attempt to meet the problem, and the four-course rotation of turnips, barley, clover, and wheat witnesses to the fact that practise has been ahead of science in this matter.—NEWMAN *Bacteria*, ch. 5, p. 161. (G. P. P., 1899.)

3139. SOILS FERTILIZED BY BACTERIA—*Future Agriculturist Will Inoculate His Fields with the Most Useful Germs.*—Experiments which are now conducting seem to indicate that there are great differences in the vitality and nitrifying ability of different nitrobacteria. It is the present work of the chemist to compare the activity of the nitrifying organisms existing in the soils of widely separated localities and to isolate, if possible, those which show the highest qualities. When this shall have been accomplished, the novel practise will be seen of practical farmers inoculating their fields with minute capillary tubes containing a colorless liquid in almost an unweighably small quantity, in which are found invisible organisms by whose multiplication the fertilities of broad acres are to be increased. As the surgeon now prepares particles of virus which, when inserted into the system, produce immunity from contagious disease, so the farmer, by a similar species of inoculation, will render possible in his soil the growth of organisms which will increase the quantity and value of his crops.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., May, 1896*, p. 38).

3140. ——— ——— *Nitrogen Essential to Fertility of Soils—Bacteria Seize Nitrogen of Air and Fix It in the Earth.*—A more important factor of soil fertility is its nitrogen content, without which it is completely barren. The origin of these nitrogen ingredients has been more or less of a puzzle. Fertile soil everywhere contains nitrates and other nitrogen compounds, and in certain parts of the world there are large accumulations of these compounds, like the nitrate beds of Chile. That they have come ultimately from the free atmospheric nitrogen seems certain, and various attempts have been made to explain a method of this nitrogen fixation. It has been suggested that electrical discharges in the air may form nitric acid, which would readily then unite with soil ingredients to form nitrates. There is little reason, however, for believing this to be a very important factor. But in the soil-bacteria we find undoubtedly an efficient agency in this nitrogen fixation. As already seen, the bacteria are able to seize the free atmospheric nitrogen, converting it into nitrites and nitrates. We have also learned that they can act in connection with legumes and some other plants, enabling them to fix atmospheric nitrogen and store it in their roots. By these two means the nitrogen ingredient in the soil is prevented from becoming exhausted by the processes of dissipation constantly going on. Further, by some such agency must we imagine the original nitrogen soil ingredient to have been derived. Such an organic agency is the only one yet discerned which appears to have been efficient in furnishing virgin soil with its nitrates, and we must therefore look upon bacteria as essential to the original fertility of the soil.—CONN *Story of Germ Life*, ch. 4, p. 115. (A., 1900.)

3141. SOLIDITY DECEPTIVE— *Earth's Surface a Thin Crust Covering a Molten Ocean.*—[We infer that the earth was once a molten mass] because the earth we tread is but a thin crust floating on a liquid sea of molten materials; because the agencies that were at work then are at work now, and the present is the logical sequence of the past. From Artesian wells, from mines, from geysers, from hot springs, a mass of facts has been collected, proving incontestably the heated condition of all substances at a certain depth below the earth's surface; and if we need more positive evidence, we have it in the fiery eruptions that even now bear fearful testimony to the molten ocean seething within the globe and forcing its way out from time to time. The modern progress of geology has led us by successive and perfectly connected steps back to a time when what is now only an occasional and rare phenomenon was the normal condition of our earth: when those internal fires were enclosed in an envelope so thin that it opposed but little resistance to their frequent outbreak, and they constantly forced themselves through this crust, pouring out melted materials that subsequently cooled and consolidated on its surface.—AGASSIZ *Geological Sketches*, ser. i, ch. 1, p. 3. (H. M. & Co., 1896.)

3142. SOLIDITY NOT REVEALED BY SIGHT—*The Visual Impression of Relief an Unconscious Derivation from Touch—Optical Illusion.*—That this idea of solidity is a matter of judgment was well shown by a photograph of a marble statue which I had an opportunity of seeing at a late exhibition. It was impossible not to believe that a marble statue was being looked at. The photograph was at the end of a room, and lighted on both sides, and not looked at through glass, nor the ordinary vision interfered with in any way. It will thus be seen that ideas of form gained by the sense of sight are essentially distinct from those derived by touch, and it is as impossible to explain to a congenitally blind man how form can be represented on a plane surface as it is to give him any ideas of color.—ELDRIDGE-GREEN *Memory and Its Cultivation*, pt. i, ch. 3, p. 11. (A., 1900.)

3143. SOLIDS CONQUERED BY YIELDING FLUIDS—*Air and Water Carve the Earth's Crust.*—We may take it that the denudation of the [earth's] surface, rendered everywhere so conspicuous by the discontinuity of strata, has been effected mainly by the atmosphere and running water.—GEIKIE *Earth Sculpture*, ch. 2, p. 40. (G. P. P., 1898.)

3144. SOLITUDE THE TERROR OF INFANCY—*A Protective Instinct.*—The great source of terror to infancy is solitude. The teleology of this is obvious, as is also that of the infant's expression of dismay—the never-failing cry—on waking up and finding himself alone.—JAMES *Psychology*, vol. ii, ch. 24, p. 418. (H. H. & Co., 1899.)

3145. SORROW RECALLS SORROW—*Memory Dominated by Mood—Joy Recalls Joy.*—The same objects do not recall the same associates when we are cheerful as when we are melancholy. Nothing, in fact, is more striking than our utter inability to keep up trains of joyous imagery when we are depressed in spirits. Storm, darkness, war, images of disease, poverty, and perishing afflict unremittingly the imaginations of melancholiacs. And those of sanguine temperament, when their spirits are high, find it impossible to give any permanence to evil forebodings or to gloomy thoughts. In an instant the train of association dances off to flowers and sunshine, and images of spring and hope.—JAMES *Psychology*, vol. i, ch. 14, p. 576. (H. H. & Co., 1899.)

3146. SOUL IN STONE—*First Explanation of Magnetic Power—The Magnet at the Foundation of Philosophy.*—Aristotle reports the sayings of Thales only by hearsay, and then with extreme caution: the

first being that everything is full of gods, and the second (and it is this which is of especial importance in our present research) that "Thales, too, as is related, seems to regard the soul as somehow producing motion, for he said that the stone has a soul, since it moves iron."

Thus we find the magnet at the very foundation of the world's philosophy. Refusing to account for the attraction of the lodestone by supernatural interposition, as the priests and worshipers at Samothrace had undoubtedly done centuries before, Thales assumed a soul or a virtue inherent and existing in the magnet itself, whereby it was enabled to move the iron.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 2, p. 33. (J. W., 1898.)

3147. "SOUL OF LIFE," THE SUPPOSED VITAL FORCE—*Physician Thought To Deal with an Unseen Personality in Disease.*—The vital force had formerly lodged as ethereal spirit, as a pneuma in the arteries; it had . . . acquired its clearest scientific position as "soul of life." *anima inscia*, in Georg Ernst Stahl, who, in the first half of the last century, was professor of chemistry and pathology in Halle. . . . Stahl's "soul of life" is, on the whole, constructed on the pattern on which the pietistic communities of that period represented to themselves the sinful human soul: it is subject to errors and passions, to sloth, fear, impatience, sorrow, indiscretion, despair. The physician must first appease it, or then incite it, or punish it, and compel it to repent. And the way in which, at the same time, he established the necessity of the physical and vital actions was well thought out. The soul of life governs the body, and only acts by means of the physicochemical forces of the substances assimilated. But it has the power to bind and to loose these forces, to allow them full play or to restrain them. After death the restrained forces become free, and evoke putrefaction and decomposition. For the refutation of this hypothesis of binding and loosing, it was necessary to discover the law of the conservation of force.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 215. (L. G. & Co., 1898.)

3148. SOUL, PSYCHOLOGY WITHOUT A—*Personality Explained by Ideas as a House by Stones and Bricks.*—Another . . . way of unifying the chaos [of mental impressions] is to seek common elements in the divers mental facts rather than a common agent behind them, and to explain them constructively by the various forms of arrangement of these elements, as one explains houses by stones and bricks. The "associationist" schools of Herbart in Germany, and of Hume, the Mills, and Bain in Britain, have thus constructed a psychology without a soul by taking discrete "ideas," faint or vivid, and showing how, by their cohesions, repulsions, and forms of succession, such things as reminiscences, perceptions, emotions, volitions, passions, theories, and all the other furnishings of an individual's mind may be engendered. The very self or *ego* of the individual comes in this way to be viewed no longer as the preexisting source of the representations, but rather as their last and most complicated fruit.—JAMES *Psychology*, vol. i, ch. 1, p. 1. (H. H. & Co., 1899.)

3149. SOUL, THE, A CAPACITY FOR GOD—*Shrinks and Shrivels without the Divine.*—The soul, in its highest sense, is a vast capacity for God. It is like a curious chamber added on to being and somehow involving being, a chamber with elastic and contractile walls which can be expanded with God as its guest, illimitably, but which without God shrinks and shrivels until every vestige of the Divine is gone, and God's image is left without God's Spirit. One cannot call what is left a soul; it is a shrunken, useless organ, a capacity sentenced to death by disuse, which droops as a withered hand by the side, and cumbers Nature like a rotted branch.—DRUMMOND *Natural Law in the Spiritual World*, essay 2, p. 98. (H. Al.)

3150. SOUL TRIUMPHS OVER BODY—*Insensibility to Pain under Strong Emotion — Soldier — Martyr — Devotee.*—Tho we speak of pleasure and pain as fixed and definite things, yet they are truly by no means fixed. It is matter of familiar experience that various circumstances may modify our sensibility in respect to things which are, in our ordinary state, painful. The power of mental excitement in this respect is well known. A soldier wounded during battle may feel no immediate suffering from the severest injury, and we have every-day proof of the same in the failure of slight accidents to pain us when we are intently occupied. All strong emotions, indeed, seem to have a similar power. It can scarcely be doubted that martyrs have sometimes gone through their flaming death in ecstasy. And the accounts we have of that fanatical sect in the East, one part of whose devotions consists in working themselves first into a frenzy, and then laying hold on glowing iron, dancing with it in their hands, and putting it to their lips, indicate not only an absence of pain in the act, but even some kind of pleasure. It would seem, indeed, that there is nothing that can be said to be always or necessarily a cause of pain. What we can truly say on this point is that there are certain things which are painful to our bodily senses when these are not controlled or modified by the state of the mind.—HINTON *The Mystery of Pain*, p. 20. (Hum., 1893.)

3151. SOUND CAUSES TERROR—*Subterranean Thunder Unexplained.*—Phenomena of sound, when unattended by any perceptible shocks, produce a peculiarly deep impression even on persons who have lived

in countries where the earth has been frequently exposed to shocks. A striking and unparalleled instance of uninterrupted subterranean noise, unaccompanied by any trace of an earthquake, is the phenomenon known in the Mexican elevated plateaux by the name of the "roaring and the subterranean thunder" *(bramidos y truenos subterraneos)* of Guanajuato. This celebrated and rich mountain city lies far removed from any active volcano. The noise began about midnight on the 9th of January, 1784, and continued for a month. I have been enabled to give a circumstantial description of it from the report of many witnesses, and from the documents of the municipality, of which I was allowed to make use. From the 13th to the 16th of January it seemed to the inhabitants as if heavy clouds lay beneath their feet, from which issued alternate slow rolling sounds and short, quick claps of thunder. The noise abated as gradually as it had begun. It was limited to a small space, and was not heard in a basaltic district at the distance of a few miles. Almost all the inhabitants, in terror, left the city, in which large masses of silver ingots were stored; but the most courageous, and those more accustomed to subterranean thunder, soon returned, in order to drive off the bands of robbers who had attempted to possess themselves of the treasures of the city. Neither on the surface of the earth, nor in mines 1,600 feet in depth, was the slightest shock to be perceived. No similar noise had ever before been heard on the elevated table-land of Mexico, nor has this terrific phenomenon since occurred there. —HUMBOLDT *Cosmos*, vol. i, p. 209. (H., 1897.)

3152. SOUND LAGGING AFTER SIGHT—*Ice-cliffs Seem to Fall in Silence—Slow Reverberations, as of Distant Battle.*—"The [Turner] glacier expands on entering the water, as is the habit of all glaciers of clear ice when unconfined, and ends in magnificent ice-cliffs some two miles in length. The water dashing against the bases of the cliffs dissolves them away, and the tide tends to raise and lower the expanded ice-foot. The result of these agencies and of the onward flow of the ice itself is to cause huge masses, sometimes reaching from summit to base of the cliffs, to topple over into the sea with a tremendous crash. Owing to the distance of the glacier from Haenke Island, we could see the ice fall long before the roar it caused reached our ears; the cliffs separated and huge masses seemed to sink into the sea without a sound; the spray thrown up as the blue pinnacles disappeared ascended like gleaming rockets, sometimes as high as the tops of the cliffs, and then fell back in silent cataracts of foam. Then a noise as of a cannonade came booming across the waters and echoing from cliff to cliff. The roar of the glacier continues all day when the air is warm and the sun is bright, and is most pronounced when the summer days are finest. Sometimes roar succeeds roar like artillery fire, and the salutes were answered, gun for gun, by the great Hubbard glacier, which pours its flood of ice into the fiord a few miles northeast of where Turner glacier terminates."—RUSSELL *Glaciers of North America*, ch. 6, p. 93. (G. & Co., 1897.)

3153. SOUND MAY QUENCH SOUND—*Interference of Sound-waves—Beats, What They Are.*—The most familiar illustration of the interference of sound-waves is furnished by the beats produced by two musical sounds slightly out of unison. When two tuning-forks in perfect unison are agitated together the two sounds flow without roughness, as if they were but one. But by attaching with wax to one of the forks a little weight, we cause it to vibrate more slowly than its neighbor. Suppose that one of them performs 101 vibrations in the time required by the other to perform 100, and suppose that at starting the condensations and rarefactions of both forks coincide. At the 101st vibration of the quickest fork they will again coincide, that fork at this point having gained one whole vibration, or one whole wave-length upon the other. But a little reflection will make it clear that, at the 50th vibration, the two forks are in opposition; here the one tends to produce a condensation where the other tends to produce a rarefaction; by the united action of the two forks, therefore, the sound is quenched, and we have a pause of silence. This occurs where one fork has gained half a wave-length upon the other. At the 101st vibration, as already stated, we have coincidence, and therefore augmented sound; at the 150th vibration we have again a quenching of the sound. Here the one fork is three half-waves in advance of the other. In general terms, the waves conspire when the one series is an even number of half-wave lengths, and they destroy each other when the one series is an odd number of half-wave lengths in advance of the other. With two forks so circumstanced, we obtain those intermittent shocks of sound, separated by pauses of silence, to which we give the name of beats. By a suitable arrangement, moreover, it is possible to make one sound wholly extinguish another. Along four distinct lines, for example, the vibrations of the two prongs of a tuning-fork completely blot each other out.—TYNDALL *Lectures on Light*, lect. 2, p. 61. (A., 1898.)

3154. SOUND, MINGLED WAVES OF—*Discriminating Power of the Ear.*—You must conceive the air of a concert-hall or ballroom as traversed in every direction, and not merely on the surface, by a variegated throng of intersecting wave-systems. From the mouths of the male singers proceed waves of six to twelve feet in length; from the lips of the songstresses dart shorter

waves, from eighteen to thirty-six inches long. The rustling of silken skirts excites little curls in the air, each instrument in the orchestra emits its peculiar waves, and all these systems expand spherically from their respective centers, dart through each other, are reflected from the walls of the room, and thus rush backwards and forwards until they succumb to the greater force of newly generated tones.

Altho this spectacle is veiled from the material eye, we have another bodily organ, the ear, especially adapted to reveal it to us. This analyzes the interdigitation of the waves, which in such a case would be far more confused than the intersection of the water undulations, and separates the several tones which compose it, and distinguishes the voices of men and women, nay, even of individuals, and of the peculiar qualities of tone given out by each instrument, the rustling of the dresses, the footfalls of the walkers, and so on.—HELMHOLTZ *On the Physiological Causes of Harmony in Music (Popular Lectures*, ser. i, p. 79). (Translated for *Scientific Side-Lights.)*

3155. SOURCE OF THE SUN'S HEAT —*By Combustion It Would Burn Out in Three Thousand Years.*—On earth the processes of combustion are the most abundant source of heat. Does the sun's heat originate in a process of this kind? To this question we can reply with a complete and decided negative, for we now know that the sun contains the terrestrial elements with which we are acquainted. Let us select from among them the two which, for the smallest mass, produce the greatest amount of heat when they combine; let us assume that the sun consists of hydrogen and oxygen, mixed in the proportion in which they would unite to form water. The mass of the sun is known, and also the quantity of heat produced by the union of known weights of oxygen and hydrogen. Calculation shows that under the above supposition the heat resulting from their combustion would be sufficient to keep up the radiation of heat from the sun for 3,021 years. That, it is true, is a long time, but even profane history teaches that the sun has lighted and warmed us for 3,000 years, and geology puts it beyond doubt that this period must be extended to millions of years. Known chemical forces are thus so completely inadequate, even on the most favorable assumption, to explain the production of heat which takes place in the sun, that we must quite drop this hypothesis.—HELMHOLTZ *Popular Lectures*, ser. ii, lect. 4, p. 178. (L. G. & Co., 1898.)

3156. SOURCE OF THE WINDS—*Circulation in Doorway of Heated Room—Currents of Aerial Ocean.*—From the heat of the sun our winds are all derived. We live at the bottom of an aerial ocean, in a remarkable degree permeable to the solar rays, and but little disturbed by their direct action. But those rays, when they fall upon the earth, heat its surface, and when they fall upon the ocean they provoke evaporation. The air in contact with the surface shares its heat, is expanded, and ascends into the upper regions of the atmosphere, while the vapor from the ocean also ascends, because of its lightness, carrying air along with it. Where the rays fall vertically on the earth, that is to say, between the tropics, the heating of the surface is greatest. Here aerial currents ascend and flow laterally, north and south, towards the poles, the heavier air of the polar regions streaming in to supply the place vacated by the light and warm air. Thus we have incessant circulation. A few days ago, in the hot room of a Turkish bath, I held a lighted taper in the open doorway, midway between top and bottom. The flame rose vertically from the taper. When placed at the bottom the flame was blown violently inwards; when placed at the top, it was blown violently outwards. Here we had two currents, or winds, sliding over each other, and moving in opposite directions. Thus, also, as regards our hemisphere, a current from the equator sets in towards the north and flows in the higher regions of the atmosphere, while, to supply its place, another flows towards the equator in the lower regions of the atmosphere. These are the upper and the lower trade winds.—TYNDALL *Heat a Mode of Motion*, lect. 8, p. 208. (A., 1900.)

3157. SPACE FILLED WITH LUMINIFEROUS ETHER—*No Empty Spot—Belief that Other Inhabited Worlds Exist.*—As far as our knowledge of space extends, we are to conceive it as the holder of the luminiferous ether, through which are interspersed, at enormous distances apart, the ponderous nuclei of the stars. Associated with the star that most concerns us we have a group of dark planetary masses revolving at various distances round it, each again rotating on its own axis; and, finally, associated with some of these planets we have dark bodies of minor note—the moons. Whether the other fixed stars have similar planetary companions or not is to us a matter of pure conjecture, which may or may not enter into our conception of the universe. But probably every thoughtful person believes, with regard to those distant suns, that there is in space something besides our system on which they shine.—TYNDALL *Fragments of Science*, vol. i, ch. 1, p. 5. (A., 1897.)

3158. SPACE IMPENETRABLE—*Giant Telescopes of Herschel and Rosse Leave Star Depths Yet Unfathomed.*—It has been said that with the telescopes with which the Herschels have surveyed the depths of heaven twenty millions of stars are visible. But these telescopes do not penetrate to the limits of the star system. In certain parts of the Milky Way Sir W. Herschel not only failed to penetrate the

star depths with his gaging telescope, tho the mirror was eighteen inches in width; but even when he brought into action his great forty-feet telescope, with its mirror four feet across, he still saw that cloudy light which speaks of star depths as yet unfathomed. Nay, the giant telescope of Lord Rosse has utterly failed to penetrate the ocean of space which surrounds us on all sides.—PROCTOR *Expanse of Heaven*, p. 302. (L. G. & Co., 1897.)

3159. SPACE, INFINITY OF—Space has no bounds. Whatever be the frontier which we may assign to it in thought, our imagination immediately flies across this frontier, and, looking beyond, still finds space. And altho we cannot comprehend the infinite, each of us feels that it is easier to conceive space as unlimited than to imagine it limited, and that it is impossible that space should not exist everywhere.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 4, p. 590. (A.)

3160. ——— ——— There may exist round our visible universe an immense space, absolutely void and desert, beyond which, at immeasurable distances, lie other universes.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 10, p. 670. (A.)

3161. SPACE, MATERIAL SUPPLIED TO EARTH FROM—*Ninety Thousand Tons of Meteoric Matter Annually Received.*—Day by day and year by year meteors are falling upon the earth, not by hundreds and thousands, but by thousands of millions. This process of growth is, however, exceedingly slow. Estimated, indeed, by the actual quantity of matter falling year by year upon the earth, it seems like a real, appreciable growth. For let us suppose that on the average each meteor of more than 140,000 millions which fall per annum weighs but a single grain. Then the earth's weight is increased each year by 20 millions of pounds, or by more than 90,000 tons. Yet this is a mere nothing compared with the actual weight of the earth. Supposing the matter thus received to be spread uniformly over the whole surface of the earth, it would form a layer less than the 800,000,000th part of an inch in thickness; so that at this rate 400 millions of years must elapse before the earth's diameter would be increased a single inch. Thus it may fairly be said that tho the earth is really acquiring new mass year by year, yet she is no longer growing appreciably in dimensions.—PROCTOR *Expanse of Heaven*, p. 178. (L. G. & Co., 1897.)

3162. SPECIALIZATION OF MOVEMENTS—*Functions Localized in Particular Regions of the Brain.*—Up to 1870 the opinion which prevailed was that which the experiments of Flourens on pigeons' brains had made plausible, namely, that the different functions of the hemispheres were not locally separated, but carried on each by the aid of the whole organ. Hitzig in 1870 showed, however, that in a dog's brain highly specialized movements could be produced by electric irritation of determinate regions of the cortex [of the brain]; and Ferrier and Munk, half a dozen years later, seemed to prove, either by irritations or excisions or both, that there were equally determinate regions connected with the senses of sight, touch, hearing, and smell.—JAMES *Psychology*, vol. i, ch. 2, p. 30. (H. H. & Co., 1899.)

3163. SPECIES, ABSOLUTENESS OF, A FALLACY—*The Doubts of Scientists.*—Much of the popular idea of the distinctness of all species rests on a fallacy, which is obvious enough when once pointed out. In systematic works every plant and animal must be referred to some species, every species is described by such and such marks, and in the books one species is as good as another. The absoluteness of species, being the postulate of the science, was taken for granted, to begin with; and so all the forms which have been named and admitted into the systematic works as species are thereby assumed to be completely distinct. All the doubts and uncertainties which may have embarrassed the naturalist when he proposed or admitted a particular species, the nice balancing of the probabilities and the hesitating character of the judgment, either do not appear at all in the record or are overlooked by all but the critical student.—ASA GRAY *Natural Science and Religion*, lect. 1, p. 39. (S., 1891.)

3164. SPECIES DEFINED—*Distinct Species of Bacteria Recognized.*—A word may be said here respecting the much-discussed question of species in bacteria. A species may be defined as "a group of individuals which, however many characters they share with other individuals, agree in presenting one or more characters of a peculiar and hereditary kind with some certain degree of distinctness." Now, as regards bacteria, there is no doubt that separate species occur and tend to remain as separate species. It is true, there are many variations, due in large measure to the medium in which the organisms are growing—variations of age, adaptation, nutrition, etc.—yet the different species tend to remain distinct. . . . But because of the occurrence of these morphological and even pathological differences it must not be argued that the demarcation of species is wholly arbitrary.—NEWMAN *Bacteria*, ch. 1, p. 29. (G. P. P., 1899.)

3165. SPECIES ONCE ABUNDANT NOW EXTINCT—*The Irish Elk.*—The magnificent Irish elk, or *Megaceros hibernicus*, which attained a height of more than ten feet, with antlers measuring eleven feet from tip to tip, may perhaps have lived to a somewhat more recent period, but appears to have had a much more restricted range [than the cave-bear, mammoth, etc.]. Its

remains have been found in Sweden, in Germany, in France as far as the Pyrenees, and in Central Italy. It seems, however, to have been most abundant in the British Isles, and especially in Ireland.—AVEBURY *Prehistoric Times*, ch. 9, p. 278. (A., 1900.)

3166. SPECIES, SUPPOSED, PROVED TO BE VARIETIES—A small butterfly *(Terias hecabe)* ranges over the whole of the Indian and Malayan regions to Australia, and everywhere exhibits great variations, many of which have been described as distinct species; but a gentleman in Australia bred two of these distinct forms *(T. hecabe* and *T. Æsiope)*, with several intermediates, from one batch of caterpillars found feeding together on the same plant. It is therefore very probable that a considerable number of supposed distinct species are only individual varieties.—WALLACE *Darwinism*, ch. 3, p. 31. (Hum.)

3167. SPECTACLE OF ACTION STIMULATES ACTION—*Value of Competition.*—The deepest spring of action in us is the sight of action in another. The spectacle of effort is what awakens and sustains our own effort. No runner running all alone on a race-track will find in his own will the power of stimulation which his rivalry with others incites, when he feels them at his heels, about to pass. When a trotting horse is "speeded," a running horse must go beside him to keep him to the pace.—JAMES *Talks to Teachers*, ch. 7, p. 53. (H. H. & Co., 1900.)

3168. SPECTROSCOPE HELPS SOLVE MYSTERY OF AURORA—*Determines What It Is Not—Its Light from Luminous Gases.*—If the light emanating from a solid or liquid incandescent body be passed through the spectroscope the resulting spectrum is continuous. If, on the contrary, the source of light is gaseous, the spectrum is composed of a certain number of bright lines or stripes, separated from each other by dark intervals. . . .

The spectrum of the aurora borealis, studied for the first time by Angstroem in 1866, is essentially a spectrum of lines; the light of the aurora is the product, therefore, of luminous gases, and not of solid or liquid incandescent particles; neither can it be due, as has sometimes been supposed, to a reflection of the light of the sun.—ANGOT *Aurora Borealis*, ch. 3, p. 42. (A., 1897.)

3169. SPECTRUM ANALYSIS—*Each Metal Gives Its Own Unvarying Bands—Distinction between Things Seemingly Identical.*—Within the camera is now placed a cylinder of carbon hollowed out at the top to receive a bit of metal; in the hollow is placed a fragment of the metal thallium. Down upon this we bring the upper carbon point, and then separate the one from the other. A stream of incandescent thallium vapor passes between them, the magnified image of which is now seen upon the screen. It is of a beautiful green color. What is the meaning of that green? We answer the question by subjecting the light to prismatic analysis. Sent through the prism, its spectrum is seen to consist of a single refracted band. Light of one degree of refrangibility, and that corresponding to this particular green, is emitted by the thallium vapor. We will now remove the thallium and put a bit of silver in its place. The arc of silver is not to be distinguished from that of thallium; it is not only green, but the same shade of green. Are they then alike? Prismatic analysis enables us to answer the question. However impossible it is to distinguish the one color from the other, it is equally impossible to confound the spectrum of incandescent silver vapor with that of thallium. In the case of silver, we have two green bands instead of one. . . . We have in these bands a perfectly unalterable characteristic of the two metals. You never get other bands than these two green ones from the silver, never other than the single green band from the thallium, never other than the three green bands from the mixture of both metals. Every known metal has its own particular bands, and in no known case are the bands of two different metals alike in refrangibility. It follows, therefore, that these spectra may be made a sure test for the presence or absence of any particular metal. If we pass from the metals to their alloys, we find no confusion. Copper gives green bands; zinc gives blue and red bands; brass, an alloy of copper and zinc, gives the bands of both metals, perfectly unaltered in position or character.—TYNDALL *Lectures on Light*, lect. 6, p. 193. (A., 1898.)

3170. ——— ——— *Gases Tell Their Story—Far-off Nebulæ Analyzed.*—If a solid or a liquid is heated to such an extent that it becomes incandescent, the spectrum which its light gives is, like the rainbow, a broad colored band without any breaks, with the well-known series of colors—red, yellow, green, blue, and violet, and in no wise characteristic of the nature of the body which emits the light.

The case is different if the light is emitted by an ignited gas or by an ignited vapor; that is, a substance vaporized by heat. The spectrum of such a body consists, then, of one or more, and sometimes even a great number, of entirely distinct bright lines, whose position and arrangement in the spectrum are characteristic for the substances of which the gas or vapor consists, so that it can be ascertained, by means of spectrum analysis, what is the chemical constitution of the ignited gaseous body. Gaseous spectra of this kind are shown in the heavenly space by many nebulæ: for the most part they are spectra which show the bright line of ignited hydrogen and oxygen, and along with it a line which, as yet, has never been again found in the spectrum

of any terrestrial element. Apart from the proof of two well-known terrestrial elements, this discovery was of the utmost importance, since it furnished the first unmistakable proof that the cosmical nebulæ are not, for the most part, small heaps of fine stars, but that the greater part of the light which they emit is really due to gaseous bodies.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 152. (L. G. & Co., 1898.)

3171. SPECULATION CONFIRMED BY OBSERVATION—*Herschel's Explorations of the Heavens.*—The purely speculative conclusions arrived at by Wright, Kant, and Lambert, concerning the general structural arrangement of the universe, and of the distribution of matter in space, have been confirmed by Sir William Herschel, on the more certain path of observation and measurement. That great and enthusiastic, altho cautious, observer was the first to sound the depths of heaven in order to determine the limits and form of the starry stratum which we inhabit, and he, too, was the first who ventured to throw the light of investigation upon the relations existing between the position and distance of remote nebulæ and our own portion of the sidereal universe. William Herschel, as is well expressed in the elegant inscription on his monument at Upton, broke through the enclosures of heaven *(cœlorum perrupit claustra)*, and, like another Columbus, penetrated into an unknown ocean, from which he beheld coasts and groups of islands, whose true position it remains for future ages to determine.—HUMBOLDT *Cosmos*, vol. i, p. 87. (H., 1897.)

3172. SPECULATION, GEOLOGICAL—*Supposed Ancient Union of England and France.*—Whether England was formerly united with France has often been a favorite subject of speculation. So early as 1605 our countryman, Verstegan, in his "Antiquities of the English Nation," observed that many preceding writers had maintained this opinion, but without supporting it by any weighty reasons. He accordingly endeavors himself to confirm it by various arguments, the principal of which are, first, the proximity and identity of the composition of the opposite cliffs and shores of Albion and Gallia, which, whether flat and sandy or steep and chalky, correspond exactly with each other: secondly, the occurrence of a submarine ridge, called "our Lady's Sand," extending from shore to shore at no great depth, and which, from its composition, appears to be the original basis of the isthmus; thirdly, the identity of the noxious animals in France and England, which could neither have swum across, nor have been introduced by man. Thus no one, he says, would have imported wolves, therefore "these wicked beasts did of themselves pass over." He supposes the ancient isthmus to have been about six English miles in breadth, composed entirely of chalk and flint, and in some places of no great height above the sea-level. The operation of the waves and tides, he says, would have been more powerful when the straits were narrower, and even now they are destroying cliffs composed of similar materials. He suggests the possible cooperation of earthquakes; and when we consider how many submarine forests skirt the southern and eastern shores of England, and that there are raised beaches at many points above the sea-level, containing fossil shells of recent species, it seems reasonable to suppose that such upward and downward movements, taking place perhaps as slowly as those now in progress in Sweden and Greenland, may have greatly assisted the denuding force of "the ocean stream."—LYELL *Principles of Geology*, bk. ii, ch. 19, p. 315. (A., 1854.)

3173. SPECULATION, PRECARIOUSNESS OF—*Newton Timid There—Doubt, Conjecture, Question.*—Sir Isaac Newton never went beyond this field [of actual observation] without a reverential impression upon his mind of the precariousness of the ground on which he was standing. On this ground he never ventured a positive affirmation, but, resigning the lofty tone of demonstration, and putting on the modesty of conscious ignorance, he brought forward all he had to say in the humble form of a doubt, or a conjecture, or a question.—CHALMERS *Astronomical Discourses*, disc. 2, p. 52. (R. Ct., 1848.)

3174. SPEECH, LOSS OF POWER OF—*Motor Aphasia.*—Motor aphasia is neither loss of voice nor paralysis of the tongue or lips. The patient's voice is as strong as ever, and all the innervations of his hypoglossal and facial nerves, except those necessary for speaking, may go on perfectly well. He can laugh and cry, and even sing; but he either is unable to utter any words at all, or a few meaningless stock phrases form his only speech; or else he speaks incoherently and confusedly, mispronouncing, misplacing, and misusing his words in various degrees. Sometimes his speech is a mere broth of unintelligible syllables. In cases of pure motor aphasia the patient recognizes his mistakes and suffers acutely from them. Now whenever a patient dies in such a condition as this, and an examination of his brain is permitted, it is found that the lowest frontal gyrus is the seat of injury. Broca first noticed this fact in 1861, and since then the gyrus has gone by the name of Broca's convolution. The injury in right-handed people is found on the left hemisphere, and in left-handed people on the right hemisphere.—JAMES *Psychology*, vol. i, ch. 2, p. 37. (H. H. & Co., 1899.)

3175. SPEECH, ONOMATOPŒIC, LIMITATIONS OF—*Imitative Words Few—Language a System of Arbitrary Signs.*—When the Englishman and the Australian

speak each in his native tongue, only such words as belong to the interjectional and imitative classes will be naturally intelligible, and, as it were, instinctive to both. Thus the savage, uttering the sound "*waow!*" as an explanation of surprise and warning, might be answered by the white man with the not less evidently significant "*sh!*" of silence, and the two speakers would be on common ground when the native indicated by the name "*bwirri*," his cudgel, flung "*whirring*" through the air at a flock of birds, or when the native described as a "*jakkal-yakkal*" the bird called by the foreigner a "*cockatoo*." With these and other very limited classes of natural words, however, resemblance in vocabulary practically ceases. The Australian and English languages each consist mainly of a series of words having no apparent connection with the ideas they signify, and differing utterly.—DANIEL WILSON *Anthropology*, ch. 6, p. 23. (Hum., 1885.)

3176. SPEECH, PURPOSE UNDERLYING — *Man Demands a Word for Each Thing.*—When a dog yelps in front of a door, and his master, understanding his desire, opens it, the dog may, after a certain number of repetitions, get to repeat in cold blood a yelp which was at first the involuntary interjectional expression of strong emotion. The same dog may be taught to "beg" for food, and afterwards come to do so deliberately when hungry. . . . In each of these separate cases the particular sign may be consciously noticed by the animal, as distinct from the particular thing signified, and will thus, so far as it goes, be a true manifestation of language. But when we come to man we find a great difference. He has a deliberate intention to apply a sign to everything. The linguistic impulse is with him generalized and systematic. For things hitherto unnoticed or unfelt he desires a sign before he has one. Even tho the dog should possess his "yelp" for this thing, his "beg" for that, and his auditory image "rat" for a third thing, the matter with him rests there. If a fourth thing interests him for which no sign happens already to have been learned, he remains tranquilly without it, and goes no further. But the man postulates it, its absence irritates him, and he ends by inventing it. This general purpose constitutes, I take it, the peculiarity of human speech, and explains its prodigious development.—JAMES *Psychology*, vol. ii, ch. 22, p. 356. (H. H. & Co., 1899.)

3177. SPEED A SAFEGUARD—*The Humming-bird Secure with Brilliant Colors—Birds of Prey Pursue in Vain.*—In their [the humming-birds'] plumage, . . . Nature has strained at every variety of effect, and reveled in an infinitude of modifications. How wonderful their garb is, with colors so varied, so intense, yet seemingly so evanescent!—the glittering mantle of powdered gold; the emerald green that changes to velvet black; ruby reds and luminous scarlets; dull bronze that brightens and burns like polished brass, and pale, neutral tints that kindle to rose and lilac-colored flame. . . .

Excessive variation in this direction is checked in nearly all other birds by the need of a protective coloring, few kinds so greatly excelling in strength and activity as to be able to maintain their existence without it. Bright feathers constitute a double danger, for not only do they render their possessor conspicuous, but, just as the butterfly chooses the gayest flower, so do hawks deliberately single out from many obscure birds the one with brilliant plumage; but the rapacious kinds do not waste their energies in the vain pursuit of humming-birds. These are in the position of neutrals, free to range at will amidst the combatants, insulting all alike, and flaunting their splendid colors with impunity. They are Nature's favorites, endowed with faculties bordering on the miraculous, and all other kinds, gentle or fierce, ask only to be left alone by them.—HUDSON *Naturalist in La Plata*, ch. 16, p. 219. (C. & H., 1895.)

3178. SPEED, MEASURABLE, OF NERVE ACTION—*Volition Takes Time.*—By a series of very ingenious and conclusive experiments, the rate of passage of the nerve-force has been shown to be about ninety feet per second. This measure is made upon the course of the nerve-threads, and does not include the passage through the gray matter of the centers, with their mass of corpuscles. Now, the time of a complete circuit of action, beginning at a stimulation of the senses, and ending in certain movements, depends partly on the time of moving along the nerves, and partly on the time of passing through the centers, where a number of corpuscles must be traversed. Estimates have been made as to this last operation, which, from the nature of the case, is likely to be somewhat various; for not only may the central mass to be penetrated be of various extent, but also there is a liability to conflicting currents. The case of least internal delay is what is termed reflex action, where a motion answers to a stimulus without the intervention of the will, as in the involuntary start from a pinch in the hand. By experiments on frogs Helmholtz found that a period of from $\frac{1}{30}$ to $\frac{1}{10}$ of a second was occupied by the reflex act; now the length of the entire nerve-tract could only be a few inches, which would hardly occupy the two-hundredth of a second, if that tract were an uninterrupted nerve thread.—BAIN *Mind and Body*, ch. 3, p. 10. (Hum., 1880.)

3179. SPEED OF MENTAL ACTION—*Association Intensely Rapid—Naming of Separate Letters—Proof-reading.*—Reading exemplifies this kind of cohesion [by mental association]. It is an uninterrupted and pro-

tracted recall of sounds by sights which have always been coupled with them in the past. I find that I can name six hundred letters in two minutes on a printed page. Five distinct acts of association between sight and sound (not to speak of all the other processes concerned) must then have occurred in each second in my mind. In reading entire words the speed is much more rapid. Valentin relates in his "Physiology" that the reading of a single page of the proof, containing 2,629 letters, took him 1 minute and 32 seconds. In this experiment each letter was understood in $\frac{1}{28}$ of a second, but owing to the integration of letters into entire words, forming each a single aggregate impression directly associated with a single acoustic image, we need not suppose as many as 28 separate associations in a sound. The figures, however, suffice to show with what extreme rapidity an actual sensation recalls its customary associates. Both, in fact, seem to our ordinary attention to come into the mind at once.—JAMES *Psychology*, vol. i, ch. 14, p. 557. (H. H. & Co., 1899.)

3180. SPEED OF TORTOISE SCIENTIFICALLY MEASURED—The tortoises [of the Galapagos Islands], when purposely moving towards any point, travel by night and day, and arrive at their journey's end much sooner than would be expected. The inhabitants, from observing marked individuals, consider that they travel a distance of about eight miles in two or three days. One large tortoise, which I watched, walked at the rate of sixty yards in ten minutes—that is 360 yards in the hour, or four miles a day, allowing a little time for it to eat on the road.—DARWIN *Naturalist's Voyage around the World*, ch. 17, p. 383. (A., 1893.)

3181. SPEED OF TRAVEL ATTAINABLE BY MEANS OF BICYCLE—*Strength, Accuracy, and Lightness Combined.*—Almost as remarkable as our railroads and steamships is the new method of locomotion by means of the bicycle and tricycle. The principle is old enough, but the perfection to which these vehicles have now attained has been rendered possible by the continuous growth of all kinds of delicate tools and machines required in the construction of the infinitely varied forms of steam-engines, dynamos, and other rapidly moving machinery. In the last century it would not have been possible to construct a modern first-class bicycle, even if any genius had invented it, except at a cost of several hundred pounds. The combination of strength, accuracy, and lightness would not then have been attainable.—WALLACE *The Wonderful Century*, ch. 1, p. 9. (D. M. & Co., 1899.)

3182. SPIRITS, DISTILLED, A MEDIEVAL DISCOVERY—*Intemperance a Chief Evil of Modern World.*—It was not till the Middle Ages that distilled spirit, tho more ancient in the east, came into use among the western nations. It was generally accepted as beneficial, as is well seen in the name of "water of life," Latin, *aquavitæ;* French, *eau-de-vie;* Irish, *usquebaugh* (for shortness, *whisky*). Alcoholic spirit is now produced in immense quantities from the refuse of wine making, brewing, sugar-refining, etc. Its employment as a habitual stimulant is among the greatest evils of the modern world, bringing about in the low levels of the population a state of degradation hardly matched in the worst ages of history.—TYLOR *Anthropology*, ch. 11, p. 269. (A., 1899.)

3183. SPIRITUALITY THE GOAL OF EVOLUTION—*Victor Hugo: "The Tadpole of an Archangel."*—What strikes one most in running the eye up this graduated ascent [of life] is that the movement is in the direction of what one can only call spirituality. From the growl of a lion we have passed to the whisper of a soul, from the motive fear to the motive sympathy; from the icy, physical barriers of space to a nearness closer than breathing; from the torturing slowness of time to time's obliteration. If evolution reveals anything, if science itself proves anything, it is that man is a spiritual being, and that the direction of his long career is towards an ever larger, richer, and more exalted life. On the final problem of man's being the voice of science is supposed to be dumb. But this gradual perfecting of instruments—and, as each arrives, the further revelation of what lies behind in Nature—this gradual refining of the mind, this increasing triumph over matter, this deeper knowledge, this efflorescence of the soul, are facts which even science must reckon with. Perhaps, after all, Victor Hugo is right: "I am the tadpole of an archangel."—DRUMMOND *Ascent of Man*, ch. 5, p. 184. (J. P. & Co., 1900.)

3184. SPLENDOR THAT CONCEALS—*Night Has Revelations Even More Sublime than Day—From Star-clusters the Distant Universe Is Unseen.*—The blaze of light from the thousand thousand stars of their [dwellers on worlds in star-clusters] firmament must blot out all light from beyond. Their whole sky—by which I here mean the illuminated air which in the case of our own daylight limits our range of view, and forms a veil beyond which we cannot penetrate—their whole sky must be far more resplendent than ours, because every part has its hundreds on hundreds of suns. In this great splendor exists a perpetual limit to all extension of their researches into the constitution of the universe. The light of their myriads of suns blinds them to lights which lie beyond; their system of suns is their universe; and tho the universe thus revealed to them is magnificent and stupendous, yet we can see how minute it is, compared with what is revealed to ourselves,

when we remember that we can perceive many hundreds of such systems of suns.

Thus we learn how an excess of light may hide more than it reveals. . . . Night has its revelations, more wonderful in reality tho less splendid in seeming than the sun which rules the day.—PROCTOR *Expanse of Heaven*, p. 218. (L. G. & Co., 1897.)

3185. SPONTANEOUSNESS OF GROWTH—*Progress without Endeavor—Volition Simply Fulfils Conditions.*—There are three lines along which one may seek for evidence of the spontaneousness of growth. The first is science. And the argument here could not be summed up better than in the words of Jesus. The lilies grow, he says, of themselves; they toil not, neither do they spin. They grow—that is, automatically, spontaneously, without trying, without fretting, without thinking. Applied in any direction—to plant, to animal, to the body or to the soul—this law holds. A boy grows, for example, without trying. One or two simple conditions are fulfilled, and the growth goes on. He thinks, probably, as little about the condition as about the result; he fulfils the conditions by habit, the result follows by nature. Both processes go steadily on from year to year apart from himself, and all but in spite of himself. One would never think of telling a boy to grow. A doctor has no prescription for growth. He can tell me how growth may be stunted or impaired, but the process itself is recognized as beyond control—one of the few and therefore very significant things which Nature keeps in her own hands.—DRUMMOND *Natural Law in the Spiritual World*, essay 3, p. 113. (H. Al.)

3186. SPONTANEOUSNESS THE ATTRIBUTE OF HUMAN INTELLECT—*Mind of Man Included in Nature.*—We must understand it [Nature] as including every agency which we see entering, or can conceive from analogy as capable of entering, into the causation of the world. First and foremost among these is the agency of our own mind and will. Yet, strange to say, all reference to this agency is often tacitly excluded when we speak of the laws of Nature. One of our most distinguished living teachers of physical science, Professor Tyndall, began, not long ago, a course of lectures on the phenomena of heat, by a rapid statement of the modern doctrine of the correlation of forces —how the one was convertible into the other—how one arose out of the other—how none could be evolved except from some other as a preexisting source. "Thus," said the lecturer, "we see there is no such thing as spontaneousness in Nature." What!—not in the lecturer himself? Was there no "spontaneousness" in his choice of words —in his selection of materials—in his orderly arrangement of experiments with a view to the exhibition of particular results? It is not probable that the lecturer was intending to deny this; it simply was that he did not think of it as within his field of view. His own mind and will were then dealing with the "laws of Nature," but they did not occur to him as forming part of those laws, or, in the same sense, as subject to them.—ARGYLL *Reign of Law*, ch. 1, p. 4. (Burt.)

3187. SPOTS ON THE SUN—*Cooled Vapors Sinking Back on Central Mass—A Coolness Exceeding All Earthly Heat.*—Just on the edge of these [sun-]spots there are spectroscopic indications of the most violent motion, and in their vicinity there are often large protuberances; they show comparatively often a rotatory motion. They may be considered to be places where the cooler gases from the outer layers of the sun's atmosphere sink down, and perhaps produce local superficial coolings of the sun's mass. To understand the origin of these phenomena, it must be remembered that the gases, as they rise from the hot body of the sun, are charged with vapors of difficultly volatile metals, which expand as they ascend, and, partly by their expansion and partly by radiation into space, must become cooled. At the same time they deposit their more difficultly volatile constituents as fog or cloud. This cooling can only, of course, be regarded as comparative; their temperature is probably, even then, higher than any temperature attainable on the earth. If now the upper layers, freed from the heavier vapors, sink down, there will be a space over the sun's body which is free from cloud. They appear then as depressions, because about them are layers of ignited vapors as much as 500 miles in height.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 160. (L. G. & Co., 1898.)

3188. ——— ——— *Solar Rotation Revealed.*—The study of solar physics may be said to have commenced with the discovery of the sun-spots, about 267 years ago. These spots were presently found to traverse the solar disk in such a way as to indicate that the sun turns upon an axis once in about twenty-six days. Nor will this rotation appear slow when we remember that it implies a motion of the equatorial parts of the sun's surface at a rate exceeding some seventy times the motion of our swiftest express trains.—PROCTOR *Other Worlds than Ours*, ch. 2, p. 35. (Burt.)

3189. SPREAD OF A PEST—*The Russian Thistle.*—About twenty years ago a colony of immigrants brought from the plains of southern Russia to the prairie region of Dakota a small quantity of flaxseed.

The flaxseed was sown in the fertile soil of the new home. It sprouted and grew. Along with it there also developed a slender, reddish plant, which seemed natural enough to the immigrants, for it had been common-

ly present in the crops on the far-away prairies from whence they came. . . .

This plant first appeared in a locality which was wooded and hilly, but in a few seasons it reached the adjacent plains, where it was rolled by the wind for miles and miles, each year afterward invading new territory. Within a dozen years it had spread throughout South Dakota, had entered North Dakota on the south, Iowa on the north, and Nebraska on the east. During the next few years it spread with marvelous rapidity, invading Minnesota, Wisconsin, Colorado, Illinois, and Ohio. Its progress was aided by the railroads that carried the seed to many distant localities, which quickly became new centers of distribution. Presumably, the plant [the Russian thistle or Russian cactus] will continue to spread by similar methods, and within a few years will be present in most of the United States.

In the plains region of southeastern Russia this plant has long been known as a noxious pest. On its account "the cultivation of crops has been abandoned over large areas in some of the provinces near the Caspian Sea." In our own West it has already caused damage amounting in a single State to millions of dollars a year.—WEED *Seed Travellers,* ch. 1, p. 21. (G. & Co., 1899.)

3190. SPREAD OF UNMOLESTED SPECIES—*Reindeer Naturalized in Iceland—Rapid Increase from Small Beginning—Man Aids Nature by Destroying Destroyers.*—As an example of the rapidity with which a large tract may become peopled by the offspring of a single pair of quadrupeds, it may be mentioned that in the year 1773 thirteen reindeer were exported from Norway, only three of which reached Iceland. These were turned loose into the mountains of Guldbringè Syssel, where they multiplied so greatly, in the course of forty years, that it was not uncommon to meet with herds, consisting of from forty to one hundred, in various districts.

The reindeer, observes a modern writer, is in Lapland a loser by his connection with man, but Iceland will be this creature's paradise. There is, in the interior, a tract which Sir G. Mackenzie computes at not less than forty thousand square miles, without a single human habitation, and almost entirely unknown to the natives themselves. There are no wolves; the Icelanders will keep out the bears, and the reindeer, being almost unmolested by man, will have no enemy whatever, unless it has brought with it its own tormenting gadfly.—LYELL *Principles of Geology,* bk. iii, ch. 41, p. 686. (A., 1854.)

3191. SPRINGS EXPLAINED BY ARTESIAN WELLS—*Lakes and Streams beneath the Earth.*—Much light has been thrown, of late years, on the theory of springs, by the boring of what are called by the French "Artesian wells," because the method has long been known and practised in Artois; and it is now demonstrated that there are sheets and in some places currents of fresh water at various depths in the earth. The instrument employed in excavating these wells is a large auger, and the cavity bored is usually from three to four inches in diameter. If a hard rock is met with it is first triturated by an iron rod, and the materials, being thus reduced to small fragments or powder, are readily extracted. To hinder the sides of the well from falling in, as also to prevent the spreading of the ascending water in the surrounding soil, a jointed pipe is introduced, formed of wood in Artois, but in other countries more commonly of metal. It frequently happens that after passing through hundreds of feet of retentive soils a water-bearing stratum is at length pierced, when the fluid immediately ascends to the surface and flows over. The first rush of the water up the tube is often violent, so that for a time the water plays like a fountain, and then, sinking, continues to flow over tranquilly, or sometimes remains stationary at a certain depth below the orifice of the well. This spouting of the water in the first instance is probably owing to the disengagement of air and carbonic acid gas, for both of these have been seen to bubble up with the water.—LYELL *Principles of Geology,* bk. ii, ch. 16, p. 233. (A., 1854.)

3192. SPUN GLASS FROM VOLCANO—*Pele's Hair—Artistic Birds' Nests—Man Imitates Nature's Product.*—Sometimes the passage of [volcanic] steam through a mass of molten glass produces large quantities of a material resembling spun glass. Small particles or shots of the glass are carried into the air and leave behind them thin, glassy filaments like a tail. At the volcano of Kilauea, in Hawaii, this filamentous volcanic glass is abundantly produced, and is known as "Pele's Hair"—Pele being the name of the goddess of the mountain. Birds' nests are sometimes found composed of this beautiful material. In recent years an artificial substance similar to this Pele's hair has been extensively manufactured by passing jets of steam through the molten slag of iron-furnaces; it resembles cotton-wool, but is made up of fine threads of glass, and is employed for the packing of boilers and other purposes.—JUDD *Volcanoes,* ch. 4, p. 71. (A., 1899.)

3193. SQUIRRELS PLANTING NUTS—*Animals as Seed Distributers.*—Even before the arrival of frosts many of these [nuts] are dropped by the aid of squirrels, gray and red, which cut the stems with their teeth. The leaves, with the help of the shifting winds, gently cover the fruit, or some portions of it, and make the best kind of protection from dry air and severe cold; and they come just in the nick of time. Dame

Nature is generous. She produces an abundance; enough to seed the earth and enough to feed the squirrels, birds, and some other animals. The squirrels eat many nuts, but I have seen them carry a portion for some distance in several directions, and plant one or two or three in a place, covering them well with soil. It may be the thought of the squirrel—I cannot read his thoughts—to return at some future time of need, as he often does. But in some cases he forgets the locality, or does not return because he has stored up more than he needs; or in some cases the squirrels leave that locality or are killed; in any such case the planted nuts are not disturbed. At all events, some of the nuts—one now and then is all that is needed—are allowed to remain where planted. In this way the squirrel is a benefit to the trees, and pays for the nuts he eats.—BEAL *Seed Dispersal*, ch. 7, p. 61. (G. & Co., 1898.)

3194. STABILITY OF NATURE ESSENTIAL TO PROSPERITY—*Earthquake Shocks Would Ruin England.*—Earthquakes alone are sufficient to destroy the prosperity of any country. If beneath England the now inert subterranean forces should exert those powers which most assuredly in former geological ages they have exerted, how completely would the entire condition of the country be changed! What would become of the lofty houses, thickly packed cities, great manufactories, the beautiful public and private edifices? If the new period of disturbance were first to commence by some great earthquake in the dead of the night, how terrific would be the carnage! England would at once be bankrupt; all papers, records, and accounts would from that moment be lost. Government being unable to collect the taxes, and failing to maintain its authority, the hand of violence and rapine would remain uncontrolled. In every large town famine would go forth, pestilence and death following in its train.—DARWIN *Naturalist's Voyage around the World*, ch. 14, p. 305. (A., 1898.)

3195. STABILITY OF THE ANCIENT MOUNTAINS—*The Evanescent Has Already Disappeared.*—Comparing mountain chain with mountain chain, we find, as might have been expected, that the oldest mountains, if they are the least prominent, are at the same time the most stable. They have endured so long that much of their primeval elevation has been lost; the weakly built structures have been demolished, and only the stronger now remain. Great rock-falls and landslips are therefore seldom heard of among such mountains. It is quite otherwise with the younger uplifts of the globe. The valleys of the Alps, the Caucasus, the Himalayas, the Cordilleras, and other chains of relatively recent age are cumbered with chaotic heaps of fallen rock-masses. From time to time peaks and whole mountain-sides collapse and slide into the valleys, and this rapid degradation will continue until every weak structure has been removed.—GEIKIE *Earth Sculpture*, ch. 5, p. 119. (G. P. P., 1898.)

3196. STAR, NEW, SUDDEN APPEARANCE OF—*The Burning of a Sun—Seen by Us Years after Its Occurrence.*—The appearance of "new stars" is not so very rare a phenomenon. Every one at all interested in such matters remembers that in 1866 a new star broke out in the Northern Crown so suddenly that it was shining as bright as the pole-star, where six hours before there had been nothing visible to the eye. Now, all stars are not as large as our sun, tho some are much larger; but there are circumstances which make it improbable that this was a small or near object, and it is well remembered how the spectroscope showed the presence of abnormal amounts of incandescent hydrogen, the material which is perhaps the most widely diffused in the universe (and which is plentiful, too, in our own bodies), so that there was some countenance to the popular notion that this was a world in flames. We were, at any rate, witnessing a catastrophe which no earthly experience can give us a notion of, in a field of action so remote that the flash of light which brought the news was unknown years on the way, so that all this—strange but now familiar thought—occurred long before we saw it happen. The star faded in a few days to invisibility to the naked eye, tho not to the telescope; and, in fact, all these phenomena at present appear rather to be enormous and sudden enlargements of the light of existing bodies than the creation of absolutely new ones; while of these "new stars" the examples may almost be said to be now growing numerous, two having appeared in the last two years.—LANGLEY *New Astronomy*, ch. 8, p. 230. (H. M. & Co., 1896.)

3197. ——— ——— *Wagoners Point Out Phenomenon to Astronomers—Wonder as in Ancient Days (Matt. ii, 2).*—The appearance of hitherto unseen stars in the vault of heaven, especially the sudden appearance of strongly scintillating stars of the first magnitude, is an occurrence in the realms of space which has ever excited astonishment. This astonishment is the greater, in proportion as such an event as the sudden manifestation of what was before invisible, but which nevertheless is supposed to have previously existed, is one of the very rarest phenomena in Nature. . . . It seems not inappropriate to quote the narrative of an eye-witness, and, by dwelling on a particular instance, to depict the vividness of the impression produced by the sight of a new star. "On my return to the Danish islands from my travels in Germany," says Tycho Brahe, "I resided for some time with my uncle, Steno Bille *(ut aulicæ vitæ fastidium lenirem)*, in the old and pleasantly situated monastery of Herritzwadt, and here

I made it a practise not to leave my chemical laboratory until the evening. Raising my eyes, as usual, during one of my walks, to the well-known vault of heaven, I observed, with indescribable astonishment, near the zenith, in Cassiopeia, a radiant fixed star, of a magnitude never before seen. In my amazement, I doubted the evidence of my senses. However, to convince myself that it was no illusion, and to have the testimony of others, I summoned my assistants from the laboratory and inquired of them, and of all the country people that passed by, if they also observed the star that had thus suddenly burst forth. I subsequently heard that in Germany wagoners and other common people first called the attention of astronomers to this great phenomenon in the heavens—a circumstance which, as in the case of non-predicted comets, furnished fresh occasion for the usual raillery at the expense of the learned."—HUMBOLDT *Cosmos*, vol. iii, p. 151. (H., 1897.)

3198. STAR-CLUSTERS—*Island Universes—Plurality of Worlds.*—The contemplation of the heavens affords no spectacle so grand and so eloquent as that of a cluster of stars. Most of them lie at such a distance that the most powerful telescopes still show them to us like star-dust. "Their distance from us is such that they are beyond, not only all our means of measurement," says Newcomb, "but beyond all our powers of estimation. Minute as they appear, there is nothing that we know of to prevent our supposing each of them to be the center of a group of planets as extensive as our own, and each planet to be as full of inhabitants as this one. We may thus think of them as little colonies on the outskirts of creation itself, and as we see all the suns which give them light condensed into one little speck, we might be led to think of the inhabitants of the various systems as holding intercourse with each other. Yet, were we transported to one of these distant clusters, and stationed on a planet circling one of the suns which compose it, instead of finding the neighboring suns in close proximity, we should see a firmament of stars around us, such as we see from the earth. Probably it would be a brighter firmament, in which so many stars would glow with more than the splendor of Sirius as to make the night far brighter than ours; but the inhabitants of the neighboring worlds would as completely elude telescopic vision as the inhabitants of Mars do here. Consequently, to the inhabitants of every planet in the cluster, the question of the plurality of worlds might be as insolvable as it is to us."—FLAMMARION *Popular Astronomy*, bk. vi, ch. 10, p. 660. (A.)

3199. ——— ——— *Minuteness of the Earth—The Vision of the Universe.*—There is still another very interesting tract of speculation, which has been opened up to us by the more recent observations of astronomy. What we allude to is the discovery of the nebulæ. We allow that it is but a dim and indistinct light which this discovery has thrown upon the structure of the universe; but still it has spread before the eye of the mind a field of very wide and lofty contemplation. Anterior to this discovery, the universe might appear to have been composed of an indefinite number of suns, about equidistant from each other, uniformly scattered over space, and each encompassed by such a planetary attendance as takes place in our own system. But we have now reason to think that instead of lying uniformly, and in a state of equidistance from each other, they are arranged into distinct clusters; that, in the same manner as the distance of the nearest fixed stars—so inconceivably superior to that of our planets from each other—marks the separation of the solar systems, so the distance of two contiguous clusters may be so inconceivably superior to the reciprocal distance of those fixed stars which belong to the same cluster as to mark an equally distinct separation of the clusters, and to constitute each of them an individual member of some higher and more extended arrangement. This carries us upwards through another ascending step in the scale of magnificence, and there leaves us in the uncertainty whether even here the wonderful progression is ended; and, at all events, fixes the assured conclusion in our minds that, to an eye which could spread itself over the whole, the mansion which accommodates our species might be so very small as to lie wrapped in microscopical concealment; and in reference to the only Being who possesses this universal eye, well might we say, "What is man, that thou art mindful of him; or the son of man, that thou shouldst deign to visit him?"—CHALMERS *Astronomical Discourses*, p. 35. (R. Ct., 1848.)

3200. STAR-COLORS DUE TO STELLAR ATMOSPHERES — *Celestial Signal-lamps.*—Hence we learn that the two stars [composing the double star Albireo or β Cygni] owe their color to the nature of their vaporous envelopes. Each star glows in reality with a white light; but the white light has in one case to pass through vapors of a somewhat ruddy hue (because absorbing blue light), and therefore this star looks ruddy, while the light of the other star shines through bluish vapors, and therefore this star looks blue. We do not yet know how it chances that the vaporous envelopes of these stars, and of other pairs of stars, differ in this way. Perhaps we shall never know. It is, however, an important gain to our knowledge to have ascertained that the colors of the double stars are not inherent, but that these stars are, as it were, celestial signal-lamps, shining through colored matter.—PROCTOR *Expanse of Heaven*, p. 225. (L. G. & Co., 1897.)

3201. STAR-COLORS REAL—*Spectrum Analysis of Double Stars.*—Spectrum analysis applied to the double stars has proved that the beautiful colors presented by these pairs are not due to the simple effect of contrast, but are real. The two suns which compose the double star β of Cygnus, one colored yellow and the other blue, show two spectra absolutely different. A similar observation, made on the two components of α Herculis, of which one is orange-colored and the other bluish green, has also shown spectra totally different. In each of these two cases the special color of each star agrees with the way in which the light is distributed in the different regions of its spectrum.—FLAMMARION *Popular Astronomy,* bk. vi, ch. 6, p. 612. (A.)

3202. STAR-DRIFTING—*Sets of Stars that Travel as Systems through Space—Ursa Major—Proctor's Prediction Verified.*—I have said that my object was to determine whether any set of stars show a tendency to drift together. . . . I predicted that whenever Dr. Huggins should apply to them [five specified stars of Ursa Major] the new spectroscopic method he would find that they were either all approaching or all receding, and at a common rate.

This prediction was exactly confirmed by the event two years later. It happened that Dr. Huggins had forgotten which of the seven stars form the drifting set of five. He proceeded, however, with his observations. He found both the remaining wheel-stars receding at the rate of about twenty miles per second. The star representing the first horse was found to be receding at the same rate, and lastly the star representing the second horse. Here, then, were five stars receding at the rate of about twenty miles per second; but Dr. Huggins supposed at the moment that these were not the five stars respecting which I had made my little prediction. On turning, however, to my "Other Worlds" (published two years before his observations were made), he found that it was the set of five stars which he had found to be thus receding at a common rate which I had described as, in my belief, forming a drifting set. I think the inference is fair that my general theory respecting local star-drifts is correct, and that among those stars which form our familiar systems there are groups traveling as systems through space.—PROCTOR *Expanse of Heaven,* p. 294. (L. G. & Co., 1897.)

3203. STARS AND NEBULÆ—*Nebulous Masses Intermixed with Stars.*—Some important points in cosmical economy have, indeed, become quite clear within the last thirty years, and scarcely any longer admit of a difference of opinion. One of these is that of the true status of nebulæ. This was virtually settled by Sir J. Herschel's description in 1847 of the structure of the Magellanic clouds; but it was not until Whewell in 1853, and Herbert Spencer in 1858, enforced the conclusions necessarily to be derived therefrom, that the conception of the nebulæ as remote galaxies, which Lord Rosse's resolution of many into stellar points had appeared to support, began to withdraw into the region of discarded and half-forgotten speculations. In the nubeculæ as Whewell insisted "there coexists in a limited compass and in indiscriminate position stars, clusters of stars, nebulæ regular and irregular, and nebulous streaks and patches. These, then, are different kinds of things in themselves, not merely different to us. There are such things as nebulæ side by side with stars and with clusters of stars. Nebulous matter resolvable occurs close to nebulous matter irresolvable."—CLERKE *History of Astronomy,* pt. ii, ch. 12, p. 505. (Bl., 1893.)

3204. STARS, A SEED-PLOT OF—*Our Sun a Star of the Milky Way.*—This seed-plot of stars [the Milky Way] is formed of objects individually invisible to the naked eye below the sixth magnitude, but so crowded that they appear to touch each other and form a nebulous gleam which all human eyes directed to the sky for thousands of years have contemplated and admired. Since it is developed like a girdle round the whole circuit of the sky, we ourselves must be in the Milky Way. The first fact which impresses our minds is that our sun is a star of the Milky Way.—FLAMMARION *Popular Astronomy,* bk. vi, ch. 10, p. 654. (A.)

3205. STARS, COUNTING OF—*Seven Thousand Visible to Naked Eye.*—According to this estimation, the number of stars of the first six magnitudes, or, in other words, the total number visible to the naked eye, is about 7,000. Excellent sight distinguishes 8,000, average sight about 5,700. Generally, we think we see many more; we believe we can count them by myriads, by millions; in this, as in other things, we are always led into exaggeration. As a matter of fact, however, the number of stars visible to the naked eye in both hemispheres all over the earth does not exceed the above figures. The stars visible to the naked eye for ordinary sight are in reality so few in number that we might easily show them in an illustration of the size of these pages, and count them: the southern hemisphere has 3,307, and the northern 2,478; total, 5,785, without counting, of course, the star-dust of the Milky Way. Thus we see with the naked eye fewer stars in the sky than there are inhabitants in a small town. It is, then, not so difficult to make their acquaintance as might be imagined. It is but an hour's amusement.—FLAMMARION *Popular Astronomy,* bk. vi, ch. 4, p. 586. (A.)

3206. STARS, DOUBLE, EFFECT OF—*Quadruple Alternation of Day and Night—Our Experience Not the Limit.*—Every one

of the worlds, in systems belonging to a double star, has a quadruple alternation, in place of that double alternation which we call day and night. There is, first, "double day," when both suns are above the horizon; next, single day with one sun; then single day with the other sun; and, lastly, true night, when both suns are below the horizon. —PROCTOR *Expanse of Heaven*, p. 228. (L. G. & Co., 1897.)

3207. STARS INNUMERABLE UNDER THE TELESCOPE—*Millions of Stars in the Milky Way.*—Let us point a telescope towards any point of this vaporous arch [the Milky Way]: suddenly hundreds, thousands of stars show themselves in the telescopic field like needle-points on the celestial vault. Let us wait for some moments, that our eye may become accustomed to the darkness of the background, and the little sparks shine out by thousands. Let us leave the instrument pointed motionless towards the same region, and there slowly passes before our dazzled vision the distant army of stars. In a quarter of an hour we see them appear by thousands and thousands. William Herschel counted 331,000 in a width of 5° in the constellation Cygnus, so nebulous to the naked eye. If we could see the whole of the Milky Way pass before us we should see 18 millions of stars.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 10, p. 653. (A.)

3208. STARS LOST FROM THE HEAVENS—*Extinguished Suns.*—There are also cases where stars which had long been known to astronomers have disappeared altogether from view, so that their place knows them no more. It is possible that they may still give out some degree of light and heat, but the most powerful telescope fails to afford any sign of their existence, so that so far as our astronomers are concerned, these stars must be regarded as extinguished suns. It is at least certain that they have lost so large a proportion of the light and heat they once possessed that the change must seriously have affected the condition of beings living in the planets which doubtless circle around these once brilliant orbs.—PROCTOR *Expanse of Heaven*, p. 197. (L. G. & Co., 1897.)

3209. STARS NEWLY SEEN SUPPOSED NEWLY CREATED—*Wandering Nations Surprised by a New Heaven.*—In a fine episode to the Ramayana, the oldest heroic poem of Indian antiquity, the stars in the vicinity of the south pole are declared for a singular reason to have been more recently created than the northern. When Brahminical Indians were emigrating from the northwest to the countries around the Ganges, from the 30th degree of north latitude to the lands of the tropics, where they subjected the original inhabitants to their dominion, they saw unknown stars rising above the horizon as they advanced toward Ceylon. In accordance with ancient practise, they combined these stars into new constellations. A bold fiction represented the later-seen stars as having been subsequently created by the miraculous power of Visvamitra, who threatened the ancient gods that he would overcome the northern hemisphere with his more richly starred southern hemisphere" (A. W. von Schlegel, in the *Zeitschrift für die Kunde des Morgenlandes*, bd. i, s. 240). While this Indian myth figuratively depicts the astonishment excited in wandering nations by the aspect of a new heaven (as the celebrated Spanish poet, Garcilaso de la Vega, says of travelers, "they change at once their country and stars," *mudan de pays y de estrellas)*, we are powerfully reminded of the impression that must have been excited, even in the rudest nations, when, at a certain part of the earth's surface, they observed large, hitherto unseen stars appear in the horizon, as those in the feet of the Centaur, in the Southern Cross, in Eridanus or in Argo, while those with which they had been long familiar at home wholly disappeared.—HUMBOLDT *Cosmos*, vol. iii, p. 137. (H., 1897.)

3210. STARS OBSERVED BY DAY—*Companion Stars Discovered.*—The idea of observing the stars by daylight with a telescope first occurred to Morin, who, with Gascoigne (about 1638, before Picard and Auzout), combined instruments of measurement with the telescope. Morin himself says: "It was not Tycho's great observations in reference to the position of the fixed stars, when, in 1582, twenty-eight years before the invention of the telescope, he was led to compare Venus by day with the sun, and by night with the stars," but "the simple idea that Arcturus and other fixed stars might, like Venus, when once they had been fixed in the field of the telescope before sunrise, be followed through the heavens after the sun had risen, that led him to a discovery which might prove of importance for the determination of longitude at sea." No one was able before him to distinguish the fixed stars in the presence of the sun. Since the employment, by Römer, of great meridian telescopes in 1691, observations of the stars by day have been frequent and fruitful in results, having been, in some cases, advantageously applied to the measurement of the double stars. Struve states that he has determined the smallest distances of extremely faint stars in the Dorpat refractor, with a power of only 320, in so bright a crepuscular light that he could read with ease at midnight. The polar star has a companion of the ninth magnitude, which is situated at only 18″ distance; it was seen by day in the Dorpat refracting telescope by Struve and Wrangel, and was in like manner observed on one occasion by Encke and Argelander.—HUMBOLDT *Cosmos*, vol. iii, p. 66. (H., 1897.)

3211. STARS OF A NEW HEMISPHERE—*Sir John Herschel Opens the Study of the Southern Skies.*—"Strongly invited," as he [Sir John Herschel] tells us himself, "by the peculiar interest of the subject, and the wonderful nature of the objects which presented themselves," he resolved to attempt the completion of the survey in the southern hemisphere. With this noble object in view, he embarked his family and instruments on board the "Mount Stewart Elphinstone," and, after a prosperous voyage, landed at Cape Town on the 16th of January, 1834. Choosing as the scene of his observations a rural spot under the shelter of Table Mountain, he began regular "sweeping" on the 5th of March. The site of his great reflector is now marked with an obelisk, and the name of Feldhausen has become memorable in the history of science, for the four years' work done there may truly be said to open the chapter of our knowledge as regards the southern skies.—CLERKE *History of Astronomy*, pt. i, ch. 2, p. 56. (Bl., 1893.)

3212. STARS OF MANY COLORS—"*Star Differeth from Star in Glory*" *(1 Cor. xv, 41)—A Suggestion of the Foundations of the New Jerusalem (Rev. xxi, 19-21).*—In the heavens there are stars of many colors; for one star differeth from another in glory. But the colors we see with the unaided eye are far less beautiful and less striking than those which are brought into view by the telescope. And among the colored stars seen by the telescope there are none more beautiful than the colored pairs of stars. Amongst these we find the most strongly marked contrasts—such combinations as green and red, orange and blue, yellow and purple; then again we sometimes see both the companions of the same color; and yet again we find combinations where the contrast, tho not so striking as in the pairs first mentioned, is nevertheless exceedingly beautiful, as when we have gold and lilac, or white and blue, or white and green stars; and lastly, we find among the smaller companions of double stars such hues as gray, fawn, ash-colored, puce, mauve, russet, and olive.—PROCTOR *Expanse of Heaven*, p. 220. (L. G. & Co., 1897.)

3213. STARS OF THE ABYSS—*Phosphorescence of Echinoderms from Deep Sea—Starfish Coruscating with Green Light.*—Among the echinoderms we have not many recorded instances of a phosphorescent light being emitted, but it is quite possible that many, if not all of them, may possess this power. The curious deep-sea form, *Brisinga*, that was first discovered by Ch. Asbjörnsen, is known to be so brilliantly phosphorescent that it has been called a veritable *gloria maris*, and writing of the curious brittle-star *Ophiacantha spinulosa* (dredged by the "Porcupine" in 584 fathoms of water), Professor Wyville Thomson remarks that the light was of a "brilliant green, coruscating from the center of the disk, now along one arm, now along another, and sometimes vividly illuminating the whole outline of the starfish."—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 81. (A., 1894.)

3214. STARS OF THE MILKY WAY—*Each Star a Sun—Myriad Centers of Light, Motion, and Power.*—The least of the stars seen in the galactic depths—even tho the telescope which reveals it be the mightiest yet made by man, so that with all other telescopes that star would be unseen—is a sun like our own. It is a mighty mass, capable of swaying by its attraction the motions of worlds, like our earth and her fellow planets, circling in their stately courses around it. It is an orb instinct with life (if one may so speak), aglow with fiery energy, pouring out each moment supplies of life and power to the worlds which circle around it. It is a mighty engine, working out the purpose of its great Creator; it is a giant heart, whose pulsations are the source whence a myriad forms of life derive support; and until the fuel which maintains its fires shall be consumed, that mighty engine will fulfil its work; until its life-blood shall be exhausted, that giant heart will throb unceasingly.—PROCTOR *Expanse of Heaven*, p. 300. (L. G. & Co., 1897.)

3215. STARS PRESENT NEW ASPECT TO MODERN WORLD—*Change Due to Precession of the Equinoxes.*—In consequence of the precession of the equinoxes the starry heavens are continually changing their aspect from every portion of the earth's surface. The early races of mankind beheld in the far north the glorious constellation of our southern hemisphere rise before them, which, after remaining long invisible, will again appear in those latitudes after the lapse of thousands of years. Canopus was fully 1° 20′ below the horizon at Toledo (39° 54′ north latitude) in the time of Columbus, and now the same star is almost as much above the horizon at Cadiz. While at Berlin and in the northern latitudes the stars of the Southern Cross, as well as α and β Centauri, are receding more and more from view, the Magellanic clouds are slowly approaching our latitudes. Canopus was at its greatest northern approximation during the last century, and is now moving nearer and nearer to the south, altho very slowly, owing to its vicinity to the south pole of the ecliptic.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 290. (H., 1897.)

3216. STARS, SPLENDOR OF, BUT PARTIALLY KNOWN TO MAN—*Our Atmosphere a Veil—Radiance in the Tropics—The Dimness of Distance.*—The splendor of these natural illuminations can hardly be conceived by our terrestrial imagination. The tints which we admire in these stars from here can give but a distant idea of the real value of their colors. Already, in pass-

ing from our foggy latitudes to the limpid regions of the tropics, the colors of the stars are accentuated, and the sky becomes a veritable casket of precious stones. What would it be if we could transport ourselves beyond the limits of our atmosphere? Seen from the moon these colors would be splendid. Antares, α Herculis, Pollux, Aldebaran, Betelgeuse, Mars, shine like rubies; the polar star, Capella, Castor, Arcturus, Procyon, are veritable celestial topazes; while Sirius, Vega, and Altair are diamonds eclipsing all by their dazzling whiteness. How would it be if we could approach the stars so as to perceive their luminous disks, instead of merely seeing brilliant points destitute of all diameter?—FLAMMARION *Popular Astronomy*, bk. vi, ch. 8, p. 637. (A.)

3217. STARS TEACH MAN'S WEAKNESS AND MAJESTY—*"What Is Man that Thou Art Mindful of Him? Thou Hast Made Him a Little Lower than the Angels" (Ps. viii, 4, 5).*—If the starry heavens, by incalculable numbers, magnitude, space, duration, and length of periods, impress man with the conviction of his own insignificance, his physical weakness, and the ephemeral nature of his existence, he is, on the other hand, cheered and invigorated by the consciousness of having been enabled, by the application and development of intellect, to investigate very many important points in reference to the laws of Nature and the sidereal arrangement of the universe.—HUMBOLDT *Cosmos*, vol. iii, p. 30. (H., 1897.)

3218. STARS THAT NEVER SET—*Circle of Perpetual Apparition.*—Now, to see the effect of the diurnal motion near the pole, let us watch any star in the north between the pole and the horizon. We shall soon see that, instead of moving from east to west, as we are accustomed to see the heavenly bodies move, it really moves towards the east. After passing the north point it begins to curve its course upwards, until, in the northeast, its motion is vertical. Then it turns gradually to the west, passing as far above the pole as it did below it, and, sinking down on the west of the pole, it again passes under it. The passage above the pole is called the upper culmination, and that below it the lower one. . . . We cannot with the naked eye follow it all the way round, on account of the intervention of daylight, but by continuing our watch every clear night for a year we should see it in every point of its course. A star following the course we have described never sets, but may be seen every clear night. If we imagine a circle drawn round the pole at such a distance as just to touch the horizon, all the stars situated within this circle will move in this way; this is therefore called the circle of perpetual apparition.—NEWCOMB *Popular Astronomy*, ch. 1, p. 11. (H., 1899.)

3219. STARS THAT SET SPEEDILY TO RISE AGAIN—*Newly Risen Comet Supposed To Be Another.*—As we go away from the pole we shall find the stars moving in larger circles, passing higher up over the pole, and lower down below it, until we reach the circle of perpetual apparition, when they will just graze the horizon. Outside this circle every star must dip below the horizon for a greater or less time, depending on its distance. If it be only a few degrees outside it will set in the northwest, or between north and northwest; and after a few hours only it will be seen to rise again between north and northeast, having done little more than graze the horizon. The possibility of a body rising so soon after having set does not always occur to those who live in moderate latitudes. In July, 1874, Coggia's comet set in the northwest about nine o'clock in the evening, and rose again about three o'clock in the morning; and some intelligent people who then saw it east of the pole supposed it could not be the same one that had set the evening before.—NEWCOMB *Popular Astronomy*, ch. 1, p. 11. (H., 1899.)

3220. STARS, TWINKLING OF, CAUSED BY OUR ATMOSPHERE—*Higher Mountains Give Purer Sky.*—Were the particles which produce the purer celestial vault all swept away, we should, unless helped by what has been called "cosmic dust," look into the blackness of celestial space. And were the whole atmosphere abolished along with its suspended matter we should have the "blackness" spangled with steady stars; for the twinkling of the stars is caused by our atmosphere. Now, the higher we ascend, the more do we leave behind us the particles which scatter the light; the nearer, in fact, do we approach to that vision of celestial space . . . Viewed, therefore, from the loftiest Alpine summits, the firmamental blue is darker than it is ever observed to be from the plains.—TYNDALL *Fragments of Science*, vol. i, ch. 5, p. 139. (A., 1897.)

3221. ——— ——— *Partly Inherent, Partly Atmospheric—The White Stars Scintillate Most, the Orange or Red Least—"Star Differeth from Star in Glory" (1 Cor. xv, 41).*—Who has not been struck with the scintillation of the stars? While the planets, even the brightest, radiate a calm and motionless light, the stars, even the least brilliant, appear more or less agitated by a wavering and variable light. This light, which glimmers sometimes vividly, sometimes feebly, in intermittent gleams, sometimes white, green, or red, like the flashing fires of a limpid diamond, seems to animate the interstellar solitudes, and makes us think of eyes opened in the heavens. It is like a calm and transparent sea on which flit lamps lighted by other mortals: the silence is as profound, but the desert is less void, and it seems that we

divine better the distant life which is in motion round each of these brilliant fires burning in infinitude. . . .

Scintillation is a phenomenon caused partly by the intrinsic light and partly by the state of our atmosphere. .

The stars which scintillate most are the white stars, like Sirius, Vega, . . . etc. [86 variations per second]. The stars which scintillate least are the orange or red stars, like Antares, Aldebaran, Arcturus, . . . etc. [56 variations per second]. There is thus a certain correspondence between the scintillation of a star and its physical constitution. . . .

Our atmosphere plays a considerable part in the scintillation; the lower a star is, the more it scintillates; the scintillation is proportional to the product which we obtain by multiplying the thickness of the layer of air traversed by the luminous ray emanating from the star by the astronomical refraction for the altitude at which it is observed.

The scintillation is more pronounced as the cold is greater; it is stronger in winter than in summer—a fact which may be noticed by everybody.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 606. (A.)

3222. STARS WITHDRAWN FROM NORTHERN SKIES—*Change in the Heavens.*—It was not more than 2,900 years before our era that the Cross (the Southern Cross) became invisible in northern Germany. The constellation had ascended as far as the tenth degree above the horizon. When it disappeared from the Baltic skies, the pyramid of Cheops had already stood five hundred years. The shepherd nation of the Hyksos invaded Egypt seven hundred years later. The past becomes apparently less remote when we can measure it by reference to memorable events.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 290. (H., 1897.)

3223. STARS WITHOUT LIGHT—*Non-luminous Bodies May Have Brilliant Satellites.*—The belief in the existence of non-luminous stars was diffused even among the ancient Greeks, and especially in the earliest ages of Christianity. It was assumed that among the fiery stars which are nourished by the celestial vapors there revolve certain other earthlike bodies, which, however, remain invisible to us. The total extinction of new stars, especially of those so carefully observed by Tycho Brahe and Kepler in Cassiopeia and Ophiuchus, appears to corroborate this opinion. Since it was at the time conjectured that the first of these stars had already twice appeared, and that, too, at intervals of nearly 300 years, the idea of annihilation and total extinction naturally gained little or no credit. The immortal author of the "Mécanique Céleste" [Laplace] bases his conviction of the existence of non-luminous masses in the universe on these same phenomena of 1572 and 1604: "These stars, that have become invisible after having surpassed the brilliancy of Jupiter, have not changed their place during the time of their being visible." (The luminous process in them has simply ceased.) "There exist, therefore, in celestial space dark bodies of equal magnitudes, and probably in as great numbers as the stars." So also Mädler, in his "Untersuchungen über die Fixstern-Systeme," says: "A dark body might be a central body; it might, like our own sun, be surrounded in its immediate neighborhood only by dark bodies like our planets. The motions of Sirius and Procyon, pointed out by Bessel, force us to the assumption that there are cases where luminous bodies form the satellites of dark masses."—HUMBOLDT *Cosmos*, vol. iii, p. 187. (H., 1897.)

3224. STATES, MENTAL, RESULT IN PHYSICAL ACTION—*Interdependence of Body and Mind.*—The psychologist is forced to be something of a nerve-physiologist. Mental phenomena are not only conditioned *a parte ante* by bodily processes; but they lead to them *a parte post.* That they lead to acts is of course the most familiar of truths, but I do not merely mean acts in the sense of voluntary and deliberate muscular performances. Mental states occasion also changes in the caliber of blood-vessels, or alteration in the heart-beats, or processes more subtle still, in glands and viscera. If these are taken into account, as well as acts which follow at some remote period because the mental state was once there, it will be safe to lay down the general law that no mental modification ever occurs which is not accompanied or followed by a bodily change. The ideas and feelings, *e. g.* which these present printed characters excite in the reader's mind not only occasion movements of his eyes and nascent movements of articulation in him, but will some day make him speak, or take sides in a discussion, or give advice, or choose a book to read, differently from what would have been the case had they never impressed his retina.—JAMES *Psychology*, vol. i, ch. 1, p. 5. (H. H. & Co., 1899.)

3225. STEAM-JETS IN NATURE—*Volcanoes the Vents for Imprisoned Waters.*—If water be subjected to sufficiently great pressure it may be raised to a very high temperature and still retain its liquid condition. When this pressure is removed, however, the whole mass passes at once into the condition of steam or water-gas, and the gas thus formed at high temperatures has a proportionably high tension. In a Papin's digester water confined in a strong vessel is raised to temperatures far above its ordinary boiling-point, and from any opening in such a vessel the steam escapes with prodigious violence. Now, at considerable depths beneath the earth's surface, and under the pressure of many hundreds or thousands of feet of solid rock, water still retaining its liquid condition may be-

come intensely heated. When the pressure is relieved by the formation of a crack or fissure in the superincumbent mass of rock, the escape of the superheated steam will be of very violent character, and may be attended with the most striking and destructive results. In the existence of high temperatures beneath the earth's surface, and the presence in the same regions of imprisoned water capable of passing into the highly elastic gas which we call steam, we have a cause fully competent to produce all the phenomena which we have described as occurring at Stromboli.—JUDD *Volcanoes*, ch. 2, p. 21. (A., 1899.)

3226. STEAM-NAVIGATION—*Its Gradual Development.*—From the earliest dawn of history men used rowing or sailing vessels for coasting trade or for crossing narrow seas. The Carthaginians sailed nearly to the equator on the west coast of Africa, and in the eleventh century the Northmen reached North America on the coast of New England. Exactly five hundred years ago Vasco da Gama sailed from Portugal round the Cape of Good Hope to India, and in the next century Columbus and his Spanish followers crossed the Atlantic in its widest part to the West Indies and Mexico. From that time sailing ships were gradually improved, till they culminated in our magnificent frigates for war purposes and the clipper ships in the China and Australian trade, which were in use up to the middle of the century. But during all this long course of development there was no change whatever in principle, and the grandest three-decker or full-rigged clipper ship was but a direct growth, by means of an infinity of small modifications and improvements, from the rudest sailing boat of the primeval savage. Then, at the very commencement of the present [nineteenth] century, the totally new principle of steam-propulsion began to be used, at first experimentally and with many failures, on rivers, canals, and lakes, till about the year 1815 coasting steamships of small size came into pretty general use. These were rapidly improved; but it was not till the year 1838 that the "Great Western," of 1,340 tons and 400 horse-power, made the passage from Bristol to New York in fourteen days, and thus inaugurated the system of ocean steam-navigation which has since developed to such an enormous extent.—WALLACE *The Wonderful Century*, ch. 1, p. 8. D. M. & Co., 1899.)

3227. STEEL AS A FACTOR IN HUMAN PROGRESS—*Iron the Universal Metal—Metallurgy Dependent on Chemistry.*—Without metal-working, civilization, as we understand it at the present day, would be impossible. Much has been made possible in the past half-century by progress in the metallurgy of iron alone. It seems almost incredible, but it is nevertheless a fact, that steel has been sold in the United States in the last few years at a price per ton which is often obtained for hay. Iron is the universal metal. It is found in every human trade, and devoted to every possible technical art. Steel, which is only a peculiar variety of iron, can be made almost as cheap as pig iron itself. Dominant in the arts of peace, as it is in the art of war, it rules every battle, whether of peace or war. It is doubtful whether any missionary effort, no matter how successful it has been, has had an influence on the development of humanity such as has been exercised by the Bessemer converter. Iron and steel are almost synonyms for progress and intelligence. It is not necessary to spend any time to show how intimately the science and art of chemistry are interwoven with the metallurgy of iron and steel. Every step has been made possible by the researches of the chemist, and every improvement in the application of chemical principles.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 22).

3228. STELLAR PERPLEXITIES—*Nebulæ, Star-clusters, or Stars in Perspective?*—A region which appears singularly rich in stars may be a true star-cluster—a subordinate star-system—or it may be a region where the line of sight passes through an almost interminable range of stars. Seemingly minute stars may form schemes of suns far smaller than our own, or than any of the leading orbs of the heavens, or they may be orbs surpassing even Sirius in magnitude and splendor, but set at depths compared with which his enormous distance is relatively as insignificant as the distance of our moon compared with the dimensions of the solar system. A cloud of light in the star-depths may be a vast mass of nebulous matter, or it may be a scheme of stars as magnificent as the most splendid of all the star-clusters discernible with the telescope.—PROCTOR *Our Place among Infinities*, p. 207. (L. G. & Co., 1897.)

3229. STILLNESS OF THE DEEP SEA—*Animals There Found Less Muscular in Consequence.*—It is very probable, however, that these currents at the bottom of the ocean are extremely slow, and as the water is never affected by tides or storms, the general character of the deep sea is probably one of calm repose. This is a matter of no little importance; for, in the consideration of the characters presented by the fauna of any particular region, it is always necessary to take into account the physical difficulties the animals have to contend against and the modifications of structure they present to combat these difficulties. Thus in a region such as that presented by the deep sea, where there are no rapid tides, we should not expect to find such a powerful set of body muscles in the free-swimming forms, nor such a firm vertebral column as in the

animals that live in more lively water.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 34. (A., 1894.)

3230. ——— ——— *Strata Deposited by Currents.*—It appears extraordinary that in some tracts of the sea adjoining the coast of England, where we know that currents are not only sweeping along rocky masses, thrown down from time to time from the high cliffs, but also occasionally scooping out channels in the regular strata, there should exist fragile shells and tender zoophytes in abundance, which live uninjured by these violent movements. The ocean, however, is in this respect a counterpart of the land; and as, on the continents, rivers may undermine their banks, uproot trees, and roll along sand and gravel, while their waters are inhabited by testaceans and fish, and their alluvial plains are adorned with rich vegetation and forests, so the sea may be traversed by rapid currents, and its bed may here and there suffer great local derangement, without any interruption of the general order and tranquillity. It has been ascertained by soundings in all parts of the world that where new deposits are taking place in the sea coarse sand and small pebbles commonly occur near the shore, while farther from land and in deeper water finer sand and broken shells are spread out over the bottom. Still farther out the finest mud and ooze are alone met with. Mr. Austen observes that this rule holds good in every part of the English Channel examined by him. He also informs us that where the tidal current runs rapidly in what are called "races," where surface undulations are perceived in the calmest weather, over deep banks, the discoloration of the water does not arise from the power of such a current to disturb the bottom at a depth of 40 or 80 fathoms, as some have supposed. In these cases a column of water sometimes 500 feet in height is moving onwards with the tide clear and transparent above, while the lower portion holds fine sediment in suspension (a fact ascertained by soundings), when suddenly it impinges upon a bank, and its height is reduced to 300 feet. It is thus made to boil up and flow off at the surface, a process which forces up the lower strata of water charged with fine particles of mud, which in their passage from the coast had gradually sunk to a depth of 300 feet or more.—LYELL *Principles of Geology*, bk. ii, ch. 21, p. 341. (A., 1854.)

3231. STILLNESS OF TROPIC NOON —*Yet Busy Life.*—A singular contrast to the scenes I have here described [the uproar of a tropical forest by night], and which I had repeated opportunities of witnessing, is presented by the stillness which reigns within the tropics at the noontide of a day unusually sultry. . . . A thermometer observed in the shade, but brought within a few inches of the lofty mass of granite rock, rose to more than 122° F. All distant objects had wavy, undulating outlines, the optical effect of the mirage. Not a breath of air moved the dust-like sand. The sun stood in the zenith, and the effulgence of light poured upon the river, and which, owing to a gentle ripple of the waters, was brilliantly reflected, gave additional distinctness to the red haze which veiled the distance. All the rocky mounds and naked boulders were covered with large, thick-scaled iguanas, gecko-lizards, and spotted salamanders. Motionless, with uplifted heads and widely extended mouths, they seemed to inhale the heated air with ecstasy. The larger animals at such times take refuge in the deep recesses of the forest, the birds nestle beneath the foliage of the trees or in the clefts of the rocks; but if in this apparent stillness of Nature we listen closely for the faintest tones, we detect a dull, muffled sound, a buzzing and humming of insects close to the earth, in the lower strata of the atmosphere. Everything proclaims a world of active organic forces. In every shrub, in the cracked bark of trees, in the perforated ground inhabited by hymenopterous insects, life is everywhere audibly manifest. It is one of the many voices of Nature revealed to the pious and susceptible spirit of man.—HUMBOLDT *Views of Nature*, p. 200. (Bell, 1896.)

3232. STIMULUS AND INCITEMENT —*The Teacher's Great Work.*—My theory of education agrees with that of Emerson, according to which instruction is only half the battle, what he calls provocation being the other half. By this he means that power of the teacher, through the force of his character and the vitality of his thought, to bring out all the latent strength of his pupil, and to invest with interest even the driest matters of detail.—TYNDALL *Forms of Water*, pref., p. 17. (A., 1899.)

3233. STONE AGE, UNIVERSALITY OF—*Fantastic Explanations of Forgotten Implements—Everywhere Man Has Risen Only by Toil and Struggle.*—One of the chief questions to be asked about the condition of any people is whether they have metal in use for their tools and weapons. If so, they may be said to be in the metal age. If they have no copper or iron, but make their hatchets, knives, spear-heads, and other cutting and piercing instruments of stone, they are said to be in the Stone Age. Wherever such stone implements are picked up, as they often are in our own plowed fields, they prove that Stone-Age men have once dwelt in the land. It is an important fact that in every region of the inhabited world ancient stone implements are thus found in the ground, showing that at some time the inhabitants were in this respect like the modern savages. In countries where the people have long been metal-workers they have often lost all memory of what these stone things are, and tell fanciful stories to account for their being met with in

plowing or digging. One favorite notion in England and elsewhere is that the stone hatchets are " thunderbolts " fallen from the sky with the lightning flash. It has been imagined that in the east, the seat of the most ancient civilizations, some district might be found without any traces of man having lived there in a state of early rudeness, so that in this part of the world he might have been civilized from the first. But it is not so. In Assyria, Palestine, Egypt, as in other lands, one may find sharp-chipped flints, which show that here also tribes in the Stone Age once lived before the use of metal brought in higher civilization.—TYLOR *Anthropology*, ch. 1, p. 25. (A., 1899.)

3234. STONE AS BUILDING MATERIAL—*Durability of—Causes of Decay—Bending of Bunker Hill Monument.*—The solvent power of water, which attacks even glass, must in time produce an appreciable effect on the most solid material, particularly where it contains, as the water of the atmosphere always does, carbonic acid in solution. The attrition of silicious dusts, when blown against a building, or washed down its sides by rain, is evidently operative in wearing away the surface, tho the evanescent portion removed at each time may not be indicated by the nicest balance. An examination of the basin which formerly received the water from the fountain at the western entrance of the Capitol, now deposited in the Patent Office, will convince any one of the great amount of action produced principally by water charged with carbonic acid. Again, every flash of lightning not only generates nitric acid (which in solution in the rain acts on the marble), but also by its inductive effects at a distance produces chemical changes along the moist wall, which are at the present time beyond our means of estimating. Also the constant variations of temperature from day to day, and even from hour to hour, give rise to molecular motions which must affect the durability of the material of a building. Recent observations on the pendulum have shown that the Bunker Hill monument is scarcely for a moment in a state of rest, but is constantly warping and bending under the influence of the ever varying temperature of its different sides.

Moreover, as soon as the polished surface of a building is made rough from any of the causes aforementioned, the seeds of minute lichens and mosses, which are constantly floating in the atmosphere, make it a place of repose, and from the growth and decay of the microscopic plants which spring from these discoloration is produced and disintegration assisted.—HENRY *Mode of Testing Building Materials, Scientific Writings*, vol. i, p. 345. (Sm. Inst., 1886.)

3235. STONE-CUTTING, ANCIENT—*Blocks Laid without Cement.*—In ancient Egypt the masons hewed and smoothed even granite and porphyry to a finish which is envied by the architects of our own day, and the pyramids of Gizeh are as wonderful for the fine masonry of their slopes, chambers, and passages as for their prodigious size. Our modern notion of a stone building is that the blocks of stone are to be fixed together with a layer of mortar to bind them, but in the old and beautiful architecture of Egypt and Greece the faced stone blocks lie on one another, having no cement to hold them, and needing none.—TYLOR *Anthropology*, ch. 10, p. 233. (A., 1899.)

3236. STONES OF ANCIENT MONUMENTS BURIED BY WORMS—*Stonehenge.*—At Stonehenge some of the outer druidical stones are now prostrate, having fallen at a remote but unknown period, and these have become buried to a moderate depth in the ground. They are surrounded by sloping borders of turf, on which recent castings were seen. Close to one of these fallen stones, which was 17 feet long, 6 feet broad, and 28½ inches thick, a hole was dug, and here the vegetable mold was at least 9½ inches in thickness. At this depth a flint was found, and a little higher up on one side of the hole a fragment of glass. The base of the stone lay about 9½ inches beneath the level of the surrounding ground, and its upper surface 19 inches above the ground.

A hole was also dug close to a second huge stone, which in falling had broken into two pieces, and this must have happened long ago, judging from the weathered aspect of the fractured ends. The base was buried to a depth of 10 inches, as was ascertained by driving an iron skewer horizontally into the ground beneath it. The vegetable mold forming the turf-covered sloping border round the stone, on which many castings had recently been ejected, was 10 inches in thickness, and most of this mold must have been brought up by worms from beneath its base.—DARWIN *Formation of Vegetable Mold*, ch. 3, p. 45. (Hum., 1887.)

3237. STORE OF NUTRIMENT IN SEED—*A Help to Plant in Struggle for Life.*—The store of nutriment laid up within the seeds of many plants seems at first sight to have no sort of relation to other plants. But from the strong growth of young plants produced from such seeds as pease and beans, when sown in the midst of long grass, it may be suspected that the chief use of the nutriment in the seed is to favor the growth of the seedlings, while struggling with other plants growing vigorously all around.—DARWIN *Origin of Species*, ch. 3, p. 71. (Burt.)

3238. STORIES ABOUT GORILLA DISCREDITED—*His Dwelling a Mere Rude Nest—Ferocity in Attack.*—Dr. Savage repudiates the stories about the gorillas carrying off women and vanquishing elephants, and then adds:

"Their dwellings, if they may be so called, are similar to those of the chimpanzee, consisting simply of a few sticks and leafy branches, supported by the crotches and limbs of trees; they afford no shelter, and are occupied only at night.

"They are exceedingly ferocious, and always offensive in their habits, never running from man, as does the chimpanzee. They are objects of terror to the natives, and are never encountered by them except on the defensive. The few that have been captured were killed by elephant-hunters and native traders, as they came suddenly upon them while passing through the forests.

"It is said that when the male is first seen he gives a terrific yell, that resounds far and wide through the forest, something like 'kh—ah! kh—ah!' prolonged and shrill. His enormous jaws are widely opened at each expiration, his under-lip hangs over the chin, and the hairy ridge and scalp are contracted upon the brow, presenting an aspect of indescribable ferocity.

"The females and young, at the first cry, quickly disappear. He then approaches the enemy in great fury, pouring out his horrid cries in quick succession."—HUXLEY *Man's Place in Nature*, p. 211. (Hum.)

3239. STORING OF THE COAL—*Earth Once a Giant Hotbed.*—There is indisputable proof . . . that all coal beds are of vegetable origin. Geologists tell us that these coal beds were formed during an age before the earth had cooled down to the temperature that it has at the present time—an age when vegetation was forced by the internal heat of the earth instead of having to receive all its warmth from the sun's rays, as we do now. Some of our readers are familiar with what is commonly termed a hotbed. A hotbed is made by putting soil on top of substances that will ferment and create heat underneath the soil. This heat from beneath will force vegetation and cause a much larger growth than there will be if left to the sun's rays alone. During the carboniferous age the earth was a great hotbed.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 3, p. 24. (F. H. & H., 1900.)

3240. STORMS MILD BY COMPARISON—*Earth's Fiercest Tempests Compared with Hurricanes on Jupiter.*—Examined by a powerful telescope, Jupiter shows all the signs of the most tremendous atmospheric disturbances. There are great bands of clouds all around him, so arranged as to imply the existence of very strong winds resembling our trade-winds. But these cloud zones change sometimes so rapidly in shape as to show that either some of the clouds have rapidly discharged their contents in rain and new clouds have been very rapidly formed, or else that great cloud-masses have been carried along with enormous rapidity by winds of hurricane force. These motions of cloud-masses on Jupiter, when interpreted by what we know of the real dimensions of Jupiter, have been found to indicate the existence of winds blowing at the rate of nearly 200 miles per hour [contrasted with the rarely attained speed of ninety miles an hour on earth]. . . . Our terrestrial storms rage sometimes for five or six days in successsion, but this is very unusual. Ordinarily, the fiercest storm blows itself out in less than three days. Now, Jovian hurricanes have been known to last for six or seven weeks.—PROCTOR *Expanse of Heaven*, p. 79. (L. G. & Co., 1897.)

3241. STORMS ON THE SUN—*Torrents of Flaming Hydrogen Thousands of Miles High.*—Outside the opaque photosphere the sun appears surrounded by a layer of transparent gases, which are hot enough to show in the spectrum bright colored lines, and are hence called the chromosphere. They show the bright lines of hydrogen, of sodium, of magnesium, and iron. In these layers of gas and of vapor about the sun enormous storms occur, which are as much greater than those of our earth in extent and in velocity as the sun is greater than the earth. Currents of ignited hydrogen burst out several thousands of miles high, like gigantic jets or tongues of flame, with clouds of smoke above them. These structures could formerly only be viewed at the time of a total eclipse of the sun, forming what were called the rose-red protuberances. We now possess a method, devised by MM. Jansen and Lockyer, by which they may at any time be seen by the aid of the spectroscope.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 158. (L. G. & Co., 1898.)

3242. ——— ——— *Tumult and Uproar behind Beneficence—The Soundless Depths of Space.*—We know something of the processes at work upon our own sun. We know of storms raging there, in which fiery vapor masses, tens of thousands of miles in breadth, sweep onward at a rate exceeding a hundredfold in velocity the swiftest rush of our express trains. We see matter flung forth from the depths beneath the sun's blazing surface to a height exceeding ten- and twenty-fold the diameter of the globe on which we live. And we know that these tremendous motions, tho they seem to take place silently, must in reality be accompanied with a tumult and uproar altogether inconceivable. We know that precisely as distance so reduces the seeming dimensions of these vapor-masses, and their seeming rate of motion, that even in the most powerful telescopes they appear like the tiniest of the clouds which fleck the bosom of the summer sky, and change as slowly in their seeming shape; so distance partly, and partly the absence of a medium to convey the sound, reduces to utter silence a noise and clangor compared with which the roar of the hurricane, the crash of the thunderbolt, the bellowing of the volcano, and the hideous groaning of

the earthquake are as absolute silence.—PROCTOR *Expanse of Heaven*, p. 300. (L. G. & Co., 1897.)

3243. STRAIN OF DESIRE TOWARD THE UNKNOWN—*Recollection by Effort.*—Whenever we seek to recall something forgotten, or to state the reason for a judgment which we have made intuitively, the desire strains and presses in a direction which it feels to be right, but towards a point which it is unable to see. In short, the absence of an item is a determinant of our representations quite as positive as its presence can ever be.—JAMES *Psychology*, vol. i, ch. 14, p. 584. (H. H. & Co., 1899.)

3244. STRATA ARRANGED FOR GEOLOGIST'S STUDY — *Granite Wedges Forced through Sandstone.*—Imagine a large wedge forced from below through a sheet of thick ice on a river or pond. First the ice rises in an angle, that becomes sharper and higher as the wedge rises; then it cracks and opens, presenting its upturned edges on both sides, and through comes the wedge. And this is a very different process, be it observed, from what takes place when the ice merely cracks and the water issues through the crack. In the one case there is a rent and water diffused over the surface; in the other there is the projecting wedge, flanked by the upturned edges of the ice; and these edges, of course, serve as indices to decide regarding the ice's thickness and the various layers of which it is composed. Now, such are the phenomena exhibited by the wedge-like granitic ridge. The lower Old Red Sandstone, tilted up against it on both sides, at an angle of about eighty, exhibits in some parts a section of well-nigh two thousand feet, stretching from the lower conglomerate to the soft, unfossiliferous sandstone, which forms in Ross and Cromarty the upper beds of the formation. There is a mighty advantage to the geologist in this arrangement. When books are packed up in a deep box or chest we have to raise the upper tier ere we can see the tier below, and this second tier ere we can arrive at a third, and so on to the bottom. But when well arranged on the shelves of a library, we have merely to run the eye along their lettered backs, and we can thus form an acquaintance with them at a glance, which in the other case would have cost us a good deal of trouble. Now, in the neighborhood of this granitic wedge, or wall, the strata are arranged, not like books in a box—such was their original position—but like books on the shelves of a library. They have been unpacked and arranged by the uptilting agent, and the knowledge of them, which could only have been attained in their first circumstances by perforating them with a shaft of immense depth, may now be acquired simply by passing over their edges. A morning's saunter gives us what would have cost, but for the upheaving granite, the labor of a hundred miners for five years.—MILLER *The Old Red Sandstone*, ch. 6, p. 98. (G. & L., 1851.)

3245. STRATA OF A MOUNTAIN—*An Amended Illustration.*—The geologists of the school of Werner used to illustrate what we may term the anatomy of the earth, as seen through the spectacles of their system, by an onion and its coats; they represented the globe as a central nucleus, encircled by concentric coverings, each covering constituting a geological formation. The onion, through the introduction of a better school, has become obsolete as an illustration; but to restore it again, tho for another purpose, we have merely to cut it through the middle, and turn downwards the planes formed by the knife. It then represents, with its coats, hills . . . such as Ben Nevis, ere the granite had perforated the gneiss, or the porphyry broken through the granite.—MILLER *The Old Red Sandstone*, ch. 2, p. 25. (G. & L., 1851.)

3246. STRATEGY OF DEER PROTECTING FAWN—*Fawn's Instinct of Flight and Concealment.*—I have had frequent opportunities of observing the young, from one to three days old, of the *Cervus campestris*—the common deer of the pampas—and the perfection of its instincts at that tender age seem very wonderful in a ruminant. When the doe with fawn is approached by a horseman, even when accompanied with dogs, she stands perfectly motionless, gazing fixedly at the enemy, the fawn motionless at her side; and suddenly, as if at a preconcerted signal, the fawn rushes directly away from her at its utmost speed, and going to a distance of six hundred to a thousand yards conceals itself in a hollow in the ground or among the long grass, lying down very close with neck stretched out horizontally, and will thus remain until sought by the dam. When very young, if found in its hiding-place, it will allow itself to be taken, making no further effort to escape. After the fawn has run away the doe still maintains her statuesque attitude, as if resolved to await the onset, and only when the dogs are close to her she also rushes away, but invariably in a direction as nearly opposite to that taken by the fawn as possible. At first she runs slowly, with a limping gait, and frequently pausing, as if to entice her enemies on, like a partridge, duck, or plover when driven from its young; but as they begin to press her more closely her speed increases, becoming greater the further she succeeds in leading them from the starting-point.

The alarm-cry of this deer is a peculiar whistling bark, a low but far-reaching sound; but when approaching a doe with young I have never been able to hear it, nor have I seen any movement on the part of the doe. Yet it is clear that in some mysterious way she inspires the fawn with sudden, violent fear, while the fawn, on its

side, instead of being affected like the young in other mammals, and sticking closer to its mother, acts in a contrary way, and runs from her.—HUDSON *Naturalist in La Plata*, ch. 6, p. 110. (C. & H., 1895.)

3247. STREAM OF LAVA HARDENED INTO STONE—*A Frozen Cataract—Eruption of Etna.*—The lava [flowing from Etna in 1669], after overflowing fourteen towns and villages, some having a population of between three and four thousand inhabitants, arrived at length at the walls of Catania. These had been purposely raised to protect the city, but the burning flood accumulated till it rose to the top of the rampart, which was sixty feet in height, and then it fell in a fiery cascade and overwhelmed part of the city. The wall, however, was not thrown down, but was discovered long afterwards by excavations made in the rock by the Prince of Biscari, so that the traveler may now see the solid lava curling over the top of the rampart as if still in the very act of falling.—LYELL *Principles of Geology*, bk. ii, ch. 25, p. 400. (A., 1854.)

3248. ——— ——— *Spectators Almost Entrapped—Hill Melted Down.*—As another illustration of the solidity of the walls of an advancing lava-stream, I may mention an adventure related by Recupero, who, in 1766, had ascended a small hill formed of ancient volcanic matter, to behold the slow and gradual approach of a fiery current, two miles and a half broad, when suddenly two small threads of liquid matter issuing from a crevice detached themselves from the main stream and ran rapidly towards the hill. He and his guide had just time to escape, when they saw the hill, which was fifty feet in height, surrounded, and in a quarter of an hour melted down into the burning mass, so as to flow on with it.—LYELL *Principles of Geology*, bk. ii, ch. 25, p. 401. (A., 1854.)

3249. STRENGTH DEVELOPED BY RESISTANCE—*Growing Plants Made Stronger by Stress and Strain.*—Many commonplace facts indicate that the mechanical strains to which upright growing plants are exposed themselves cause increase of the dense deposits by which such plants are enabled to resist such strains. There is the fact that the massiveness of a tree-trunk varies according to the stress habitually put upon it. . . . A tree trained against a wall has a less bulky stem than a tree of the same kind growing unsupported; and between the long, weak branches of the one and the stiff ones of the other there are decided contrasts. Garden plants, which when held up by tying them to sticks have weaker stems than when they are unpropped, and sink down if their props are taken away. . . . Trees growing on inclined rocky surfaces send into crevices that afford little moisture or nutriment roots which nevertheless become thick where they are so directed as to bear great strains.—SPENCER *Biology*, pt. iv, ch. 4, p. 275. (A., 1900.)

3250. ——— ——— *Strongest Corals Grow in Hardest Surf—Vital Energies Conquer Mechanical Power.*—It has been a question with some naturalists which part of a reef is most favorable to the growth of coral. The great mounds of living porites and of millepora round Keeling atoll occur exclusively on the extreme verge of the reef, which is washed by a constant succession of breakers; and living coral nowhere else forms solid masses. At the Marshall Islands the larger kinds of coral, . . . "which form rocks measuring several fathoms in thickness," prefer . . . the most violent surf. I have stated that the outer margin of the Maldiva atolls consists of living corals (some of which, if not all, are of the same species with those at Keeling atoll), and here the surf is so tremendous that even large ships have been thrown, by a single heave of the sea, high and dry on the reef, all on board thus escaping with their lives. . . . The vital energies of the corals conquer the mechanical power of the waves; and the large fragments of reef torn up by every storm are replaced by the slow but steady growth of the innumerable polypifers which form the living zone on its outer edge. . . . It is certain that the strongest and most massive corals flourish where most exposed.—DARWIN *Coral Reefs*, ch. 4, p. 85. (A., 1900.)

3251. STRENGTH, MAN'S, PROPORTIONED TO EARTHLY NEEDS—*Weakness of Gravity on the Moon—Cyclopean Amphitheaters and Volcanoes.*—Gravity at the surface of the moon is weaker than with us; if we represent by 1,000 the force which causes objects to adhere to the terrestrial globe, that on the moon would be represented by 164. Hence, objects weigh there six times less than here; they are attracted six times less strongly. A stone weighing one pound, if transported to the moon, would not weigh more than 3 ounces. A man weighing 11 stone on our planet would not weigh there more than 26 pounds. If we imagine a man transported to our satellite, if we suppose, moreover, that his muscular powers would remain the same in this new abode, he would be able to raise weights five to six times heavier than on the earth, and his own body itself would seem to be five or six times lighter. The least muscular effort would enable him to spring to enormous heights or to run with the speed of a locomotive. [It must be observed] what a considerable part this weakness of gravity has played in the topographical organization of the lunar world, by permitting the volcanoes to pile up giant mountains on Cyclopean amphitheaters, and with a powerful hand to toss Alps upon Pyrenees.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 3, p. 110. (A.)

3252. STRENGTH OF STRUCTURE ADAPTED TO RESISTANCE—*Shells of Plymouth Breakwater—Weakest against Least Exposure.*—The same species of mollusk has often a shell comparatively weak and thin, or a shell comparatively robust and strong, according as it lies in tranquil or in stormy water. The shell which is much exposed needs to be stronger than the shell which is less exposed. But it is obvious that the mere fact of the need cannot supply the thing needed, unless by the adjustment of some machinery for the purpose. How the vital forces of the mollusk can thus be made to work to order, under a change of external conditions, we do not know. But we do know, as a matter of fact, that the shell is thickened and strengthened according as it needs resisting power. This result does not appear to arise from any difference in the amount of lime held in solution in the water, but from some power in the secreting organs of the animal to appropriate more or less of it according to its own need. The effects of this power are seen where there is no difference of condition except difference of exposure. It is said that they are observable, for example, in the shells which lie on the different sides of Plymouth breakwater—the sheltered side and the exposed side. The same power of adaptation is seen in many other forms. Trees which are most exposed to the blast are the most strongly anchored in the soil. Limbs which are the most used are the most developed. Organs which are in constant use are strengthened, whilst organs in habitual disuse have a tendency to become weaker.—ARGYLL *Reign of Law,* ch. 5, p. 128. (Burt.)

3253. STRENGTH, SURPRISING—*Physical Effect of Emotion.*—Of the almost superhuman strength and agility with which the body seems endowed, when the whole energy is concentrated upon some nervo-muscular effort, especially under the influence of an overpowering emotion, the following remarkable example has been communicated to the writer by a gentleman on whom he can place full reliance, and who was personally cognizant of the fact: An old cook-maid, tottering with age, having heard an alarm of fire, seized an enormous box containing her whole property, and ran downstairs with it as easily as she would have carried a dish of meat. After the fire had been extinguished she could not lift the box a hair's breadth from the ground, and it required two men to convey it upstairs again.—CARPENTER *Mental Physiology,* ch. 7, p. 328. (A., 1900.)

3254. STRENGTH UNDERMINED—*White Ants Eat Out the Substance of Timber from Within.*—Either from the desire to remain undiscovered [according to Büchner], or from their liking for darkness, they [the white ants] have the remarkable habit of destroying and gnawing everything from within outwards, and of leaving the outside shell standing, so that from the outside appearance the dangerous state of the inside is not perceptible. If, for instance, they have destroyed a table or other piece of household furniture, in which they always manage from the ground upwards to hit exactly the places on which the feet of the article rest, the table looks perfectly uninjured outside, and people are quite astonished when it breaks down under the slightest pressure. The whole inside is eaten away, and only the thinnest shell is left standing. If fruits are lying on the table they also are eaten out from the exact spot on which they rest on the surface of the table. In similar fashion things consisting wholly of wood, such as wooden ships, trees, etc., are destroyed by them so that they finally break in without any one having noticed the mischief.—ROMANES *Animal Intelligence,* ch. 5, p. 201. (A., 1899.)

3255. STRESS OF EMOTION MAKES PAST SEEM DISTANT—*A Great Sorrow Quickly Seems Old.*—Our representation of the position of a given event in the past is . . . determined by the movement of imagination in going back to it from the present. And this is the same thing as to say that it depends on our retrospective sense of the intervening space. That is to say, the sense of distance in time, as in space, is the recognition of a term to a movement. . . . A very recent event, bringing with it a deep mental shock and a rapid stirring of wide tracts of feeling and thought, may get to look old in a marvelously short space of time. An announcement of the loss of a dear friend, when sudden and deeply agitating, will seem remote even after an hour of such intense emotional experience.—SULLY *Illusions,* ch. 10, p. 254. (A., 1897.)

3256. STRIFE IN NATURE—*The Struggle for Existence—Parasites Have Brought Famine to Man.*—In thus obtaining possession of the earth by conquest [of animals], and defending our acquisitions by force, we exercise no exclusive prerogative. Every species which has spread itself from a small point over a wide area must, in like manner, have marked its progress by the diminution or the entire extirpation of some other, and must maintain its ground by a successful struggle against the encroachments of other plants and animals. That minute parasitic plant, called "the rust" in wheat, has, like the Hessian fly, the locust, and the aphis, caused famines ere now amongst the "lords of the creation." The most insignificant and diminutive species, whether in the animal or vegetable kingdom, have each slaughtered their thousands, as they disseminated themselves over the globe, as well as the lion, when first it spread itself over the tropical regions of Africa.—LYELL *Principles of Geology,* bk. iii, ch. 41, p. 688. (A., 1854.)

3257. STRUCTURE OF THE HEAVENS, COMPLICATED—*Nebulæ of Many Types—The Magellanic Clouds—Contrasted with Starless Spaces, the "Coal Sacks."*—Mysterious objects [the nebulæ], voices of the past, prophecies of the future, these soft and pale gleams open to the mind new perspectives in infinitude; the first telescopic observers of the sky, who treasured the memory of the empyrean, described them as openings through the celestial vault, permitting our gaze to penetrate to the light of Paradise. The types on which we have fixed our attention give still but an incomplete idea. We should add the lenticular and elliptical nebulæ; the perforated nebulæ; nebulous rays; the great cloud of Magellan, at 20° from the south pole, which contains 291 nebulæ, 46 stellar clusters, and 582 stars, and covers 42 square degrees of the sky; the smaller cloud, which occupies 10 square degrees, contains 200 stars, 37 nebulæ, and 7 clusters; and not far from that the "coal sacks," regions entirely void of stars, yawning openings in the sidereal universe, as if a waterspout had devastated them; and, again, the faintest nebulæ lost in the depths of the sky, whose light would take, according to the Herschelian estimates, two millions of years to reach us!—FLAMMARION *Popular Astronomy*, bk. vi, ch. 10, p. 665. (A.)

3258. STRUGGLE AND CONFLICT BEHIND THE BEAUTY AND ORDER OF NATURE—To most persons Nature appears calm, orderly, and peaceful. They see the birds singing in the trees, the insects hovering over the flowers, the squirrel climbing among the tree-tops, and all living things in the possession of health and vigor and in the enjoyment of a sunny existence. But they do not see and hardly ever think of the means by which this beauty and harmony and enjoyment are brought about. They do not see the constant and daily search after food, the failure to obtain which means weakness or death; the constant effort to escape enemies; the ever-recurring struggle against the forces of Nature. This daily and hourly struggle, the incessant warfare, is nevertheless the very means by which much of the beauty and harmony and enjoyment in Nature are produced, and also affords one of the most important elements in bringing about the origin of species.—WALLACE *Darwinism*, ch. 2, p. 10. (Hum.)

3259. ——— ——— *Among All Plants—The More Vigorous Choke the Weaker (Matt. xiii, 7).*—"All the plants of a given country," says De Candolle, in his usual spirited style, "are at war one with another. The first which establish themselves by chance in a particular spot tend, by the mere occupancy of space, to exclude other species—the greater choke the smaller; the longest livers replace those which last for a shorter period; the more prolific gradually make themselves masters of the ground which species multiplying more slowly would otherwise fill." In this continual strife it is not always the resources of the plant itself which enable it to maintain or extend its ground. Its success depends, in a great measure, on the number of its foes or allies among the animals and plants inhabiting the same region. Thus, for example, an herb which loves the shade may multiply, if some tree with spreading boughs and dense foliage flourish in the neighborhood. Another, which, if unassisted, would be overpowered by the rank growth of some hardy competitor, is secure because its leaves are unpalatable to cattle, which, on the other hand, annually crop down its antagonist, and rarely suffer it to ripen its seed.—LYELL *Principles of Geology*, bk. iii, ch. 40, p. 670. (A., 1854.)

3260. STRUGGLE FOR LIFE, THE—*Among Ants.*—Almost everything is invaded by the structures of ants. Where there are no real nests there are underground passages and galleries, open roads, covered ways; or, at least, the inhabitants of neighboring nests are out scouting, contending with one another for the possession of plants containing plant-lice and cochineal kermes, for the possession of the trees, the flowers, and the insect plunder. . . . Ants certainly, no less than men, fancy themselves the lords of creation; for, owing to their social organization, their numbers, and their courage, they have few foes to fear. Their most formidable foes are other ants, just as men are the worst foes of men. In the tropical world the struggle for existence is much fiercer than with us, and the ants, with their immense number of species, play a much more important part. Their nest-structures are correspondingly more varied there, displaying far more singular and complicated adaptations as the result of the struggle for life.—FOREL *Ants' Nests (Report of Smithsonian Institution, 1894*, p. 503).

3261. ——— ——— *Among Bacteria.*—There is in these media [water and sewage] in Nature a keen struggle for the survival of the fittest bacteria for each special medium. In a carcass it is the same. If saprophytic bacteria [bacteria of decomposition] are present with pathogenic [disease-producing], there is a struggle for the survival of the latter. Now whilst this is in part due to a competition owing to a limited food supply and an unlimited population, as occurs in other spheres, it is also due in part to the inimical influence of the chemical products of the one species upon the life of the bacteria of the other species. Moreover, in one culture medium, as Cast has pointed out, two species will often not grow. When Pasteur found that exposure to air attenuated his cultures, he pointed out that it was not the air *per se* that hindered his growth, but it was the introduc-

tion of other species which competed with the original.—NEWMAN *Bacteria*, ch. 1, p. 34. (G. P. P., 1899.)

3262. ——— ——— *Conflict Most Severe between Allied Forms.*—The dependency of one organic being on another, as of a parasite on its prey, lies generally between beings remote in the scale of Nature. This is likewise sometimes the case with those which may be strictly said to struggle with each other for existence, as in the case of locusts and grass-feeding quadrupeds. But the struggle [for life] will almost invariably be most severe between the individuals of the same species, for they frequent the same districts, require the same food, and are exposed to the same dangers. —DARWIN *Origin of Species*, ch. 3, p. 69. (Burt.)

3263. ——— ——— *Family Relieves—Duties Distributed—Character Developed.* —Great as are the physical advantages of the family, the ethical uses, even in the early days of its existence, place this institution at the head of all the creations of evolution. For the family is not only its greatest creation, but its greatest instrument for further creation. The ethical changes begin almost the moment it is formed. One immediate effect, for instance, of the formation of family groups was to take off from any single individual the perpetual strain of the struggle for life. The family as a whole must sometimes fight, but the responsibility and the duty are now distributed, and those who were once solely preoccupied with the personal struggle will have respites during which other things will occupy their minds. Attention thus called off from environing enemies, the members of the family will, as it were, discover one another. New relations among them will spring up, new adjustments to one another's presence and to one another's needs, and hitherto unknown elements of character will be gradually called to the surface.—DRUMMOND *Ascent of Man*, ch. 9, p. 310. (J. P., 1900.)

3264. ——— ——— *Its Intensity Transcends Calculation.*—Every one has heard that when an American forest is cut down a very different vegetation springs up; but it has been observed that ancient Indian ruins in the southern United States, which must formerly have been cleared of trees, now display the same beautiful diversity and proportion of kinds as in the surrounding virgin forests. What a struggle must have gone on during long centuries between the several kinds of trees, each annually scattering its seeds by the thousand; what war between insect and insect, between insects, snails, and other animals, with birds and beasts of prey, all striving to increase, all feeding on each other, or on the trees, their seeds and seedlings, or on the other plants which first clothed the ground and thus checked the growth of the trees! Throw up a handful of feathers and all fall to the ground according to definite laws; but how simple is the problem where each shall fall compared to that of the action and reaction of the innumerable plants and animals which have determined, in the course of centuries, the proportional numbers and kinds of trees now growing on the old Indian ruins!—DARWIN *Origin of Species*, ch. 3, p. 69. (Burt.)

3265. ——— ——— *Not the Only Element in Evolution—The "Villain" Not the Only Actor in the Drama.*—That the struggle for life has been a prominent actor in the drama is certain. Further research has only deepened the impression of the magnitude and universality of this great and far-reaching law. But that it is the sole or even the main agent in the process of evolution must be denied. Creation is a drama, and no drama was ever put upon the stage with only one actor. The struggle for life is the "villain" of the piece, no more; and, like the "villain" in the play, its chief function is to react upon the other players for higher ends.—DRUMMOND *Ascent of Man*, int., p. 12. (J. P., 1900.)

3266. ——— ——— *Painfulness of, among the Lower Animals—Less Painful than We Imagine—Nature Takes by Force the Sacrifice Not Freely Made.*—The probabilities are that the struggle for life in the lower creation is, to say the least, less painful than it looks. Whether we regard the dulness of the states of consciousness among lower animals, or the fact that the condition of danger must become habitual, or that death when it comes is sudden, and unaccompanied by that anticipation which gives it its chief dread to man, we must assume that whatever the struggle for life subjectively means to the lower animals, it can never approach in terror what it means to us. And as to putting any moral content into it, until a late stage in the world's development, that is not to be thought of. Judged of even by later standards, there is much to relieve one's first unfavorable impression. With exceptions, the fight is a fair fight. As a rule, there is no hate in it, but only hunger. It is seldom prolonged and seldom wanton. As to the manner of death, it is generally sudden. As to the fact of death, all animals must die. As to the meaning of an existence prematurely closed, it is better to be to be eaten than not to be at all. And, as to the last result, it is better to be eaten out of the world and, dying, help another to live, than pollute the world by lingering decay. The most, after all, that can be done with life is to give it to others. Till Nature taught her creatures of their own free will to offer the sacrifice, is it strange that she took it by force?—DRUMMOND *Ascent of Man*, ch. 6, p. 203. (J. P., 1900.)

3267. ——— ——— *Subordinated to Higher Aims—The Evolution of Motherhood—The Struggle for Another's Life Begun.*—Watch any higher animal at that most critical of all hours—for itself, and for its species—the hour when it gives birth to another creature like itself. Pass over the purely physiological processes of birth; observe the behavior of the animal-mother in presence of the new and helpless life which palpitates before her. There it lies, trembling in the balance between life and death. Hunger tortures it; cold threatens it; danger besets it; its blind existence hangs by a thread. There is the opportunity of evolution. There is an opening appointed in the physical order for the introduction of a moral order. If there is more in Nature than the selfish struggle for life the secret can now be told. Hitherto, the world belonged to the food-seeker, the self-seeker, the struggler for life, the father. Now is the hour of the mother. And, animal tho she be, she rises to her task. And that hour, as she ministers to her young, becomes to her, and to the world, the hour of its holiest birth.—Drummond *Ascent of Man*, p. 17. (J. P., 1900.)

3268. STUDENT OF FACTS CAN ALONE DETERMINE THEORY—But none have a right to question either the sanity or the sanctity of such investigations, still less to dismiss them idly on a priori grounds, till they have approached the practical problem for themselves, and heard at least the first few relevant words from Nature. For one has only to move for a little among the facts to see what a world of interest lies here, and to be forced to hold the judgment in suspense till the sciences at work upon the problem have further shaped their verdict.—Drummond *Ascent of Man*, ch. 4, p. 121. (J. P., 1900.)

3269. STUDENTS OF PURE SCIENCE MAKE DISCOVERIES—*Others Make Industrial Application.*—Cuvier, the great comparative anatomist, writes thus . . . : "These grand, practical innovations are the mere applications of truths of a higher order, not sought with a practical intent, but pursued for their own sake, and solely through an ardor for knowledge. Those who applied them could not have discovered them; those who discovered them had no inclination to pursue them to a practical end. Engaged in the high regions whither their thought had carried them, they hardly perceived these practical issues, tho born of their own deeds. These rising workshops, these peopled colonies, those ships which furrow the seas—this abundance, this luxury, this tumult—all this comes from discoverers in science, and it all remains strange to them. At the point where science merges into practise they abandon it; it concerns them no more."—Tyndall *Lectures on Light*, p. 223. (A., 1898.)

3270. STUDY, FAVORITE, MENTAL BENEFIT OF—*Biology Gives the Mind Breadth and Tone.*—Mr. Hamerton has well said, "To have one favorite study, and live in it with happy familiarity, and cultivate every portion of it diligently and lovingly, as a small yeoman proprietor cultivates his own land, this, as to study, at least, is the most enviable intellectual life." And if a study should be sought for which shall most pleasantly aid in the cultivation of the inner life just described it will assuredly be found more readily within the domain of biology than in any other department of human knowledge. To act as such a mental stimulant; to effectually prevent the occurrence of that miserable disease of female mental existence—ennui; to give the mind breadth and tone from the beginning of its cultivation—such are the benefits I claim for the school study of biology, carried in its natural development into the after-life of the pupil of either sex.—Andrew Wilson *Biology in Education*, p. 25. (Hum., 1888.)

3271. STUDY OF NATURE LIMITED BY TRADITIONAL BELIEFS—*Existence of Sun-spots Denied—The Sun Studied by Night in Aristotle.*—It was Father Scheiner, a Jesuit of Ingolstadt, who first effectually called attention to the sun-spots, and this, so to say, in spite of himself and in spite of his superior. The day-star was regarded and honored as the purest symbol of celestial incorruptibility, and the official savants of that age would never have dared to consent to the admission of these spots. It would have been then a crime of high treason, and dogma itself would have appeared to be compromised. After his repeated observations, which would not permit him to doubt their existence, our Jesuit went to consult the provincial father of his order, a zealous peripatetic philosopher, who refused to believe it. "I have read the whole of my Aristotle several times," he replied to Scheiner, "and I can assure you that I have found nothing similar there. Go, my son," added he, dismissing him; "quiet yourself, and be certain that there are defects in your glasses or in your eyes which you take for spots on the sun." They even say that he passed the night in ascertaining the state of the day-star! At this epoch academical routine still domineered over the study of Nature. Very fortunately for science, unfettered minds would observe: what Scheiner did in Germany, Galileo did in Italy, and the solar spots were verified as facts by all those who wished to see them.—Flammarion *Popular Astronomy*, bk. iii, ch. 3, p. 253. (A.)

3272. STUPIDITY OF INSTINCT—*Cats Endlessly Baffled by Same Trick—All Experience Vain.*—A curious instance . . . was brought to my notice . . . by one of my neighbors, a native. His children had made the discovery that some excite-

ment and fun were to be had by placing a long, hollow stalk of the giant thistle with a mouse in it—and every hollow stalk at this time had one for a tenant—before a cat, and then watching her movements. Smelling her prey, she would spring at one end of the stalk—the end towards which the mouse would be moving at the same time—but would catch nothing; for the mouse, instead of running out, would turn back to run to the other end, whereupon the cat, all excitement, would jump there to seize it; and so the contest would continue for a long time, an exhibition of the cleverness and the stupidity of instinct, both of the pursuer and the pursued.—HUDSON *Naturalist in La Plata*, ch. 3, p. 61. (C. & H., 1895.)

3273. ——— ——— *Example of Contrasted Intelligence.*—There were several cats at the house, and all acted in the same way [as that described in paragraph 3272] except one. When a stalk was placed before this cat, instead of becoming excited like the others, it went quickly to one end and smelt at the opening; then, satisfied that its prey was inside, it deliberately bit a long piece out of the stalk with its teeth, then another strip, and so on progressively, until the entire stick had been opened up to within six or eight inches of the further end, when the mouse came out and was caught. Every stalk placed before this cat was demolished in the same businesslike way; but the other cats, tho they were made to look on while the stick was being broken up by their fellow, could never learn the trick.—HUDSON *Naturalist in La Plata*, ch. 3, p. 61. (C. & H., 1895.)

3274. ——— ——— *No Power of Adaptation to New Needs and Perils.*—The nature of this lizard's food [the Amblyrhyncus of the Galapagos Islands], as well as the structure of its tail and feet, and the fact of its having been seen voluntarily swimming out at sea, absolutely prove its aquatic habits; yet there is in this respect one strange anomaly, namely, that when frightened it will not enter the water. Hence it is easy to drive these lizards down to any little point overhanging the sea, where they will sooner allow a person to catch hold of their tails than jump into the water. . . . I threw one several times as far as I could into a deep pool left by the retiring tide, but it invariably returned in a direct line to the spot where I stood. It swam near the bottom, with a very graceful and rapid movement, and occasionally aided itself over the uneven ground with its feet. . . . I several times caught this same lizard by driving it down to a point, and tho possessed of such perfect powers of diving and swimming, nothing would induce it to enter the water; and as often as I threw it in it returned in the manner above described. Perhaps this singular piece of apparent stupidity may be accounted for by the circumstance that this reptile has no enemy whatever on shore, whereas at sea it must often fall a prey to the numerous sharks. Hence, probably, urged by a fixed and hereditary instinct that the shore is its place of safety, whatever the emergency may be, it there takes refuge.—DARWIN *Naturalist's Voyage around the World*, ch. 17, p. 386. (A., 1893.)

3275. STUPIDITY OF THE HORSE —*Utility of Limited Intelligence.*—The horse is a densely stupid animal, as far as everything goes except contiguous association. We reckon him intelligent, partly because he looks so handsome, partly because he has such a wonderful faculty of contiguous association and can be so quickly molded into a mass of set habits. Had he anything of reasoning intelligence he would be a less faithful slave than he is.—JAMES *Psychology*, vol. ii, ch. 22, p. 353. (H. H. & Co., 1899.)

3276. SUBLIMITY AND BEAUTY ARE IN THE SOUL—To Switzerland belongs the rock—to the early climber, competent to enjoy them, belong the sublimity and beauty of mass, form, color, and grouping. And still the outward splendor is by no means all. "In the midst of a puddly moor," says Emerson, "I am afraid to say how glad I am," which is a strong way of affirming the influence of the inner man as regards the enjoyment of external Nature. And surely the inner man is a high factor in the effect. The magnificence of the world outside suffices not. Like light falling upon the polished plate of the photographer, the glory of Nature, to be felt, must descend upon a soul prepared to receive its image and superscription.—TYNDALL *Hours of Exercise in the Alps*, ch. 25, p. 301. (A., 1898.)

3277. SUBLIMITY OF VASTNESS—*The Steppes Once the Bottom of an Inland Sea.*—The steppes themselves [were once] the bottom of some vast inland sea. Even now illusion often recalls, in the obscurity of night, these images of a former age. For when the guiding constellations illumine the margin of the plain with their rapidly rising and setting beams, or when their flickering forms are reflected in the lower stratum of undulating vapor, a shoreless ocean seems spread before us. Like a limitless expanse of waters, the steppe fills the mind with a sense of the infinite, and the soul, freed from the sensuous impressions of space, expands with spiritual emotions of a higher order. But the aspect of the ocean, its bright surface diversified with rippling or gently swelling waves, is productive of pleasurable sensations, while the steppe lies stretched before us cold and monotonous, like the naked, stony crust of some desolate planet.—HUMBOLDT *Views of Nature*, p. 1. (Bell, 1896.)

3278. SUBMERGENCE AND ELEVATION OF CONTINENTS—*Marine Fossils in Inland Rocks—Warm Seasons in Arctic Regions.*—The greater part of the marine

fossils known to us are from rocks now raised up in our continents, and they lived at periods when the continents were submerged. Now, in geological time these periods of submergence alternated with others of elevation; and it is manifest that each period of continental submergence gave scope for the introduction of numbers of new marine species, while each continental elevation, on the other hand, gave opportunity for the increase of land life. Further, periods when a warm climate prevailed in the arctic regions—periods when plants such as now live in temperate regions could enjoy six months of continuous sunshine—were eminently favorable to the development of such plants, and were utilized for the introduction of new floras, which subsequently spread to the southward. Thus we see physical changes occurring in an orderly succession, and made subservient to the progress of life.—DAWSON *Facts and Fancies in Modern Science*, lect. 3, p. 125. (A. B. P. S.)

3279. ——— ——— *The Glacial Period —The Walrus Swimming among Sunken Fir-trees of England.*—There is a writing upon the wall of cliffs at Cromer, and whoso runs may read it. It tells us, with an authority which cannot be impeached, that the ancient sea-bed of the chalk sea was raised up and remained dry land until it was covered with forest, stocked with the great game whose spoils have rejoiced your geologists. . . . That dry land, with the bones and teeth of generations of long-lived elephants, hidden away among the gnarled roots and dry leaves of its ancient trees, sank gradually to the bottom of the icy sea, which covered it with huge masses of drift and boulder clay. Sea-beasts, such as the walrus, now restricted to the extreme north, paddled about where birds had twittered among the topmost twigs of the fir-trees. How long this state of things endured we know not, but at length it came to an end. The upheaved glacial mud hardened into the soil of modern Norfolk. Forests grew once more, the wolf and the beaver replaced the reindeer and the elephant; and at length what we call the history of England dawned. —HUXLEY *Lay Sermons*, serm. 9, p. 194. (G. P. P., 1899.)

3280. SUBSIDENCE, GRADUAL, OF EARTH'S CRUST—*Coral Islands a Proof.* —There are many large spaces of ocean, without any high land, interspersed with reefs and islets formed by the growth of those kinds of coral which cannot live at great depths; and the existence of these reefs and low islets in such numbers and at such distant points is inexplicable, excepting on the theory that their rocky bases slowly and successively sank beneath the level of the sea, whilst the corals continued to grow upwards. No positive facts are opposed to this view, and some direct evidence, as well as general considerations, render it probable.—DARWIN *Coral Reefs*, ch. 5, p. 132. (A., 1900.)

3281. SUBSIDENCE OF GRECIAN COAST—*Deluge of Samothrace—Capitals of Columns in Fishing Nets.*—As to the deluge of Samothrace, which is generally referred to a distinct date, it appears that the shores of that small island and the adjoining mainland of Asia were inundated by the sea. Diodorus Siculus says that the inhabitants had time to take refuge in the mountains and save themselves by flight; he also relates that long after the event the fishermen of the island drew up in their nets the capitals of columns, which were the remains of cities submerged by that terrible catastrophe. These statements scarcely leave any doubt that there occurred, at the period alluded to, a subsidence of the coast, accompanied by earthquakes and inroads of the sea. It is not impossible that the story of the bursting of the Black Sea through the Thracian Bosphorus into the Grecian Archipelago, which accompanied and, as some say, caused the Samothracian deluge, may have reference to a wave, or succession of waves, raised in the Euxine by the same convulsion.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 356. (A., 1854.)

3282. SUBSIDENCE OF LAND IN EARTHQUAKE—*Sudden Death in Fissures of the Earth.*—In the year 1692 the island of Jamaica was visited by a violent earthquake; the ground swelled and heaved like a rolling sea, and was traversed by numerous cracks, two or three hundred of which were often seen at a time, opening and then closing rapidly again. Many people were swallowed up in these rents; some the earth caught by the middle and squeezed to death; the heads of others only appeared above ground; and some were first engulfed and then cast up again with great quantities of water. Such was the devastation that even in Port Royal, then the capital, where more houses are said to have been left standing than in the whole island besides, three-quarters of the buildings, together with the ground they stood on, sank down, with their inhabitants, entirely under water. . . . The large storehouses on the harbor side subsided, so as to be twenty-four, thirty-six, and forty-eight feet under water, yet many of them appear to have remained standing, for it is stated that after the earthquake the mastheads of several ships wrecked in the harbor, together with the chimney-tops of houses, were just seen projecting above the waves. A tract of land round the town, about a thousand acres in extent, sank down in less than one minute during the first shock, and the sea immediately rolled in.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 504. (A., 1854.)

3283. SUBSIDENCE OF THE QUAY AT LISBON—*Crowds Engulfed under Sea and Land.*—Among other extraordinary events

related to have occurred at Lisbon during the catastrophe [the earthquake of 1755] was the subsidence of a new quay, built entirely of marble at an immense expense. A great concourse of people had collected there for safety, as a spot where they might be beyond the reach of falling ruins; but suddenly the quay sank down with all the people on it, and not one of the dead bodies ever floated to the surface. A great number of boats and small vessels anchored near it, all full of people, were swallowed up as in a whirlpool. No fragments of these wrecks ever rose again to the surface, and the water in the place where the quay had stood is stated, in many accounts, to be unfathomable; but Whitehurst says he ascertained it to be one hundred fathoms. — LYELL *Principles of Geology*, bk. ii, ch. 29, p. 495. (A., 1854.)

3284. SUBSISTENCE OF PRIMEVAL IMPULSE—*The Instinct of Habitation—Man Seeks at Once Shelter and Protection.*—There can be no doubt that the instinct to seek a sheltered nook, open only on one side, into which he may retire and be safe, is in man quite as specific as the instinct of birds to build a nest. It is not necessarily in the shape of a shelter from wet and cold that the need comes before him, but he feels less exposed and more at home when not altogether unenclosed than when lying all abroad. Of course the utilitarian origin of this ininstinct is obvious. But to stick to bare facts at present and not to trace origins, we must admit that this instinct now exists, and probably always has existed, since man was man. Habits of the most complicated kind are reared upon it. But even in the midst of these habits we see the blind instinct cropping out; as, for example, in the fact that we feign a shelter within a shelter by backing up beds in rooms with their heads against the wall, and never lying in them the other way—just as dogs prefer to get under or upon some piece of furniture to sleep, instead of lying in the middle of the room. The first habitations were caves and leafy grottoes, bettered by the hands; and we see children to-day, when playing in wild places, take the greatest delight in discovering and appropriating such retreats and "playing house" there.—JAMES *Psychology*, vol. ii, ch. 24, p. 426. (H. H. & Co., 1899.)

3285. SUBSTITUTES FOR NAILS, CLAMPS, AND SCREWS AMONG AMERICAN INDIANS—*Fire as a Tool.*—For nails and screws the Western mechanics employed "tree-nails" and all sorts of rope and twine and sinew-cord and rawhide string. They also made excellent glues and cements, from both vegetal and animal substances. For tightening a joint, they knew how to take advantage in the twisting of a rope. The power that can be put into a half-inch sinew-rope, by means of a trusty lever, is very great. The Eskimo bow is thus tightened. These mechanics were well versed in the use of fire as a tool, excavating and bending wood thereby, and among some tribes the bow was rendered more elastic in this manner.—MASON *Aboriginal American Mechanics (Memoirs of International Congress of Anthropology*, p. 74). (Sch. P. C.)

3286. SUBSTITUTES FOR VISE AND PINCERS — *Ingenuity of Adaptation.* — For grasping hot stones the American mechanics used tongs of wood, and in lieu of vises and strong pincers they resorted to the shrinking of vegetable fiber and of rawhide. They made a kind of clamp of two stout bits of wood, wrapped the two ends with spruce-root or rawhide, wet, and allowed it to dry. In this way the parts of a box could be held until they were sewed.—MASON *Aboriginal American Mechanics (Memoirs of International Congress of Anthropology*, p. 73). (Sch. P. C.)

3287. SUBSTITUTION OF FACULTIES GIVES ECONOMY OF POWER—*Aids to Memory—Dependence on One's Individuality.*—The same result may, in many cases, be achieved by different faculties. A man who can only remember facts should not trouble to try to learn by heart; there are very few cases in which the substance is not sufficient.

Those who can very easily learn by heart should use concise books, as their tendency will be to learn the words and miss the sense.

A man who cannot remember details should try to classify everything, and remember a general rule for the whole, as French words by the terminations, etc.

A man who can remember reasons better than anything else should try to find a reason for everything, simply as an aid to memory, using a bad reason instead of none at all.

The artist should make mental pictures of a subject, if not in a position to be able to draw them on paper. An artist's sketchbook often forms an admirable diary—that is, directly he looks at the drawings he has made the accompanying circumstances occur to his mind, and those which happened about that time, the names of the friends he was staying with, and the amusements they indulged in, all "coming back."—ELDRIDGE-GREEN *Memory and its Cultivation*, pt. ii, p. 275. (A., 1900.)

3288. SUCCESS AT OUTSET—*Habit of Achievement—Barbarians and Europeans.*—The need of securing success at the outset is imperative. Failure at first is apt to dampen the energy of all future attempts, whereas past experience of success nerves one to future vigor. Goethe says to a man who consulted him about an enterprise, but mistrusted his own powers: "Ach! you need only blow on your hands!" And the remark illustrates the effect on Goethe's spirits of his own habitually successful career. Professor Baumann, from whom I borrow the

anecdote, says that the collapse of barbarian nations when Europeans come among them is due to their despair of ever succeeding as the newcomers do in the larger tasks of life.—JAMES *Psychology*, vol. i, ch. 4, p. 124. (H. H. & Co., 1899.)

3289. SUCCESS TENDS TO BECOME A HABIT— It is matter of experience that . . . feelings of successful achievement do tend to fix in our memory whatever processes have led to them.—JAMES *Psychology*, vol. i, ch. 2, p. 71. (H. H. & Co., 1899.)

3290. SUFFERING OF ANIMALS LESS THAN CONJECTURED—There is, I think, good reason to believe that . . . the supposed "torments" and "miseries" of animals have little real existence, but are the reflection of the imagined sensations of cultivated men and women in similar circumstances, and that the amount of actual suffering caused by the struggle for existence among animals is altogether insignificant.—WALLACE *Darwinism*, ch. 2, p. 25. (Hum.)

3291. SUGAR SCIENTIFICALLY PRODUCED—*The Beet-sugar Industry.*—We see in the development of the beet-sugar industry in that country [Germany] an illustration of the immense industrial importance of pure and applied chemistry. On a soil not naturally fertile and exhausted by twenty centuries of agriculture, and in a climate not of the most hospitable kind, chemical science has developed a great industry which successfully competes with the warmth of climate and fertility of soil of the most favored tropical regions. Last year the German Empire produced nearly two million tons of sugar, a quantity as great as that produced by the whole world a little over a quarter of a century ago.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 17).

3292. SUGGESTION A CAUSE OF ILLUSION—*Mental Impression Appears Objective.*—A suggested impression may appear so vividly before the mind as to completely overpower a real impression. Thus, I was once traveling by railroad to Battersea Park, and firmly believed that I had passed Chelsea, and that the next station was Battersea Park. When the train reached Chelsea I looked out of the carriage at the signboard, and saw Battersea Park there, as I expected, and got out of the train, but soon noticed that I had alighted at the wrong station; I felt perfectly convinced that I had seen Battersea Park on the signboard, and went back to look, of course only finding Chelsea. There was no mistake in the sense of one word being mistaken for another, for the words Battersea Park are not the least like the word Chelsea, and I looked directly at the signboard, and plainly saw Battersea Park. Such is the probable origin of a good many ghosts.—ELDRIDGE-GREEN *Memory and its Cultivation*, pt. i, ch. 7, p. 171. (A., 1900.)

3293. ——— ——— *Vision of Byron Seen after His Death by Sir Walter Scott.*—It is mentioned by Sir Walter Scott, in his "Demonology and Witchcraft," that having been engaged in reading with much interest, soon after the death of Lord Byron, an account of his habits and opinions, he was the subject of the following illusion:

Passing from his sitting-room into the entrance hall, fitted up with the skins of wild beasts, armor, etc., he saw right before him, and in a standing posture, the exact representation of his departed friend, whose recollection had been so strongly brought to his imagination. He stopped for a single moment so as to notice the wonderful accuracy with which fancy had impressed upon the bodily eye the peculiarities of dress and posture of the illustrious poet. Sensible, however, of the delusion, he felt no sentiment save that of wonder at the extraordinary accuracy of the resemblance, and stepped onwards towards the figure, which resolved itself, as he approached, into the various materials of which it was composed. These were merely a screen occupied by greatcoats, shawls, plaids, and such other articles as are usually found in a country entrance-hall. Sir Walter returned to the spot from which he had seen this product of what may be called imagination proper, and tried with all his might to recall it by the force of his will, but in vain.—CARPENTER *Mental Physiology*, ch. 5, p. 207. (A., 1900.)

3294. SUMMATION OF STIMULI—*Repeated Impulses Give Effect.*—We constantly use the summation of stimuli in our practical appeals. . . . If we are striving to remember a lost name or fact we think of as many "cues" as possible, so that by their joint action they may recall what no one of them can recall alone. The sight of a dead prey will often not stimulate a beast to pursuit, but if the sight of movement be added to that of form pursuit occurs. . . . "Dr. Allen Thomson hatched out some chickens on a carpet, where he kept them for several days. They showed no inclination to scrape, . . . but when Dr. Thomson sprinkled a little gravel on the carpet . . . the chickens immediately began their scraping movements." A strange person, and darkness, are both of them stimuli to fear and mistrust in dogs (and, for the matter of that, in men). Neither circumstance alone may awaken outward manifestations, but together, *i. e.*, when the strange man is met in the dark, the dog will be excited to violent defiance. Street-hawkers well know the efficacy of summation, for they arrange themselves in a line upon the sidewalk, and the passer often buys from the last one of them, through the effect of the reiterated solicitation, what

he refused to buy from the first in the row.—JAMES *Psychology*, vol. i, ch. 3, p. 84. (H. H. & Co., 1899.)

3295. SUN AS A FURNACE—*Pennsylvania's Coal Supply as Fuel—The Sun's Heat Constant through All Historic Time.*—How is this heat [of the sun] maintained? Not by the miracle of a perpetual self-sustained flame, we may be sure. But, then, by what fuel is such a fire fed? There can be no question of simple burning, like that of coal in the grate, for there is no source of supply adequate to the demand. The State of Pennsylvania, for instance, is underlaid by one of the richest coal-fields of the world, capable of supplying the consumption of the whole country at its present rate for more than a thousand years to come. If the source of the solar heat (whatever that is) were withdrawn, and we were enabled to carry this coal there, and shoot it into the solar furnace fast enough to keep up the known heat supply, so that the solar radiation would go on at just its actual rate, the time which this coal would last is easily calculable. It would not last days or hours, but the whole of these coal-beds would demonstrably be used up in rather less than one one-thousandth of a second! We find by a similar calculation that if the sun were itself one solid block of coal it would have burned out to the last cinder in less time than man has certainly been on the earth. But during historic times there has as surely been no noticeable diminution of the sun's heat, for the olive and the vine grow just as they did three thousand years ago, and the hypothesis of an actual burning becomes untenable.—LANGLEY *New Astronomy*, ch. 4, p. 97. (H. M. & Co., 1896.)

3296. SUN A STAR—*But a Point as Seen from Other Stars—Night Wraps the Universe Except around Each Star.*—Let us suppose ourselves, then. on the sun nearest to ours. From there our dazzling furnace is already lost like a little star, hardly recognizable among the constellations: earth, planets, comets sail in the invisible. We are in a new system. If we thus approach each star we find a sun, while all the other suns of space are reduced to the rank of stars. Strange reality!—the normal state of the universe is night. What we call day only exists for us because we are near a star.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 1, p. 554. (A.)

3297. SUN, CHROMOSPHERE OF, AN OCEAN OF FIRE—*Metals in Vapor—Mountains of Glowing Hydrogen.*—Below the corona [of the sun], descending, we find the chromosphere, a sheet of fire from 6,000 to 9,000 miles in thickness, and which, here and there, is projected in immense masses which we might call flames, if this expression were not, in spite of its eloquence, very much below the reality. We call flame and fire that which burns; but the gases of the solar atmosphere are raised to such a degree of temperature that it is impossible for them to burn! Extremes meet. Hydrogen forms the upper part of the chromosphere; but as we descend we find vapors of magnesium, iron, and a great number of metals. The prominences are due to projections of hydrogen, shot up with velocities which exceed 240,000 meters (149 miles) per second. The eruption sometimes continues during several hours and even during several days, and these immense luminous clouds remain suspended without moving until they fall back in showers of fire on the solar surface. How can we conceive, how express, these tremendous operations of solar nature! If we call the chromosphere an ocean of fire, it should be added that it is an ocean hotter than the most intense fiery furnace, and also deeper than the Atlantic is wide. If we call these movements hurricanes, it should be remarked that our hurricanes blow with a force of 100 miles an hour, while on the sun they blow with a violence of 100 miles a second! Shall we compare them to volcanic eruptions? Vesuvius buried Pompeii and Herculaneum under its lava; a solar eruption rising in a few seconds to 60,000 miles in height would swallow up the entire earth in its rain of fire, and reduce to ashes all terrestrial life in less time than you take to read these lines. If our globe could fall into the sun it would melt and evaporate on arriving there like a flake of snow on red-hot iron.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 5, p. 296. (A.)

3298. SUN LIFTS GLACIER TO MOUNTAIN—*Brings River Down.*—The sun, by the act of vaporization, lifts mechanically all the moisture of our air, which when it condenses falls in the form of rain, and when it freezes falls as snow. In this solid form it is piled upon the Alpine heights, and furnishes materials for glaciers. But the sun again interposes, liberates the solidified liquid, and permits it to roll by gravity to the sea. The mechanical force of every river in the world as it rolls towards the ocean is drawn from the heat of the sun. No streamlet glides to a lower level without having been first lifted to the elevation from which it springs by the power of the sun. The energy of winds is also due entirely to the same power.—TYNDALL *Fragments of Science*, vol. i, ch. 16, p. 378. (A., 1897.)

3299. SUN NOT STATIONARY—*Solar System Moves toward Constellation Hercules.*—The sun is not motionless in space. He moves on and draws with him the earth and the whole planetary system. We have detected his motion by that of the stars. When we travel on the railway, with the velocity of the new Pegasus of modern science, through countries diversified with fields, meadows, woods, hills, and villages, we see all the objects flying past us in a direction opposite to that of our motion. Well, by carefully watching the stars, we

observe an analogous fact in celestial objects. The stars appear animated with motions which draw them apparently towards a certain region of the sky—that which is behind us. On each side of us they seem to fly past, and the constellations which are in front of us appear to enlarge so as to open for us a passage. Calculation has shown that these perspective appearances are caused by the translation of the sun, the earth, and all the planets towards a region of the sky marked by the constellation Hercules. We travel towards that region with a velocity which it is difficult to determine exactly, but which appears to be from 400 to 500 millions of miles per annum. We leave the starry latitudes where Sirius sparkles, and we sail towards those where shine the stars of Lyra and of Hercules. The earth has never passed twice over the same course.—FLAMMARION *Popular Astronomy*, bk. i, ch. 5, p. 50. (A.)

3300. SUN SUPPOSED TO BE PURE AND QUENCHLESS FIRE—*Hence the Alchemists' Quest for an Ever-burning Lamp.*—To look across the space of over ninety million miles, and to try to learn from that distance the nature of the solar heat, and how it is kept up, seemed to the astronomers of the last century a hopeless task. The difficulty was avoided rather than met by the doctrine that the sun was pure fire, and shone because "it was its nature to." In the Middle Ages such an idea was universal; and along with it, and as a logical sequence of it, the belief was long prevalent that it was possible to make another such flame here, in the form of a lamp which should burn forever and radiate light endlessly without exhaustion. With the philosopher's stone, which was to transmute lead into gold, this perpetual lamp formed a prime object of research for the alchemist and student of magic.

We recall the use which Scott has made of the belief in this product of "gramarye" in the "Lay of the Last Minstrel," where it is sought to open the grave of the great wizard in Melrose Abbey. It is midnight when the stone which covers it is heaved away, and Michael's undying lamp, buried with him long ago, shines out from the open tomb and illuminates the darkness of the chancel.

I would you had been there to see
The light break forth so gloriously;
That lamp shall burn unquenchably
Until the eternal doom shall be,

says the poet. Now we are at liberty to enjoy the fiction as a fiction; but if we admit that the art which could make such a lamp would indeed be a black art, which did not work under Nature's laws, but against them, then we ought to see that, as the whole conception is derived from the early notion of a miraculous constitution of the sun, the idea of an eternal self-sustained sun is no more permitted to us than that of an eternal self-sustained lamp. We must look for the cause of the sun's heat in Nature's laws.—LANGLEY *New Astronomy*, ch. 4, p. 91. (H. M. & Co., 1896.)

3301. SUN THE SOURCE OF TERRESTRIAL ENERGY—*Decay the Recoiling of the Bent Spring.*—All terrestrial energy comes from the sun, and every manifestation of power on the earth can be traced directly back to his energizing and life-giving rays. The force with which oxygen tends to unite with the other elements may be regarded as a spring, which the sun's rays have the power to bend. In bending this spring they do a certain amount of work, and when, in the process of combustion, the spring flies back, the energy reappears. Moreover, the instability of all organized forms is but a phase of the same action, and the various processes of decay, with the accompanying phenomenon of death, are simply the recoiling of the same bent spring. Amid all these varied phenomena, the one element which reappears in all, and frequently wholly engrosses our attention, is energy.—COOKE *New Chemistry*, lect. 10, p. 235. (A., 1899.)

3302. ——— ——— *Delicacy as Well as Power Due to Central Orb.*—We have . . . been led to recognize the sun as the ultimate material source of all the energy which we possess, and we must now regard him as the source likewise of all our delicacy of construction. It requires the energy of his high-temperature rays so to wield and manipulate the powerful forces of chemical affinity, so to balance these various forces against each other, as to produce in the vegetable something which will afford our frames not only energy, but also delicacy of construction. Low-temperature heat would be utterly unable to accomplish this; it consists of ethereal vibrations which are not sufficiently rapid, and of waves that are not sufficiently short, for the purpose of shaking asunder the constituents of compound molecules. It thus appears that animals are, in more ways than one, pensioners upon the sun's bounty.—STEWART *Conservation of Energy*, ch. 6, p. 413. (Hum., 1880.)

3303. ——— ——— *Deprivation of Sunlight Would Speedily Destroy All Activity on Earth.*—When we come to inquire for the source of the energy which lifts the water from the sea to the mountain-top, which decomposes the carbonic acid of the atmosphere and plant-foods of the soil, and builds up the hydrocarbons and other fuels of animal and vegetable tissue, we find it always mainly in the solar rays. I say mainly, because, of course, the light and heat of the stars, the impact of meteors, and the probable slow contraction of the earth, are all real sources of energy, and contribute their quota. But, as compared with the energy derived from the sun, their total amount is probably something like the ratio of starlight to sunlight; so

small that it is quite clear . . . that a month's deprivation of the solar rays would involve the utter destruction of all activity upon the earth.—YOUNG *The Sun*, int., p. 4. (A., 1898.)

3304. ——— ——— *Our Varied Powers Derived from Its Heat—All Life Due to Solar Influence.*—Everything which moves, circulates, and lives on our planet is the child of the sun. . . . The most nutritious foods come from the sun. The wood which warms us in winter is, again, the sun in fragments; every cubic inch, every pound of wood, is formed by the power of the sun. The mill which turns under the impulse of wind or water revolves only by the sun. And in the black night, under the rain or snow, the blind and noisy train which darts like a flying serpent through the fields, rushes along above the valleys, is swallowed up under the mountains, goes hissing past the stations, of which the pale eyes strike silently through the mist—in the midst of night and cold this modern animal, produced by human industry, is still a child of the sun; the coal from the earth which feeds its stomach is solar work stored up during millions of years in the geological strata of the globe. As it is certain that the force which sets the watch in motion is derived from the hand which has wound it, so it is certain that all terrestrial power proceeds from the sun. It is its heat which maintains the three states of bodies—solid, liquid, and gaseous; the last two would vanish, there would be nothing but solids, water, and air itself would be in massive blocks, if the solar heat did not maintain them in the fluid state. It is the sun which blows in the air, which flows in the water, which moans in the tempest, which sings in the unwearied throat of the nightingale. It attaches to the sides of the mountains the sources of the rivers and glaciers, and consequently the cataracts and the avalanches are precipitated with an energy which they draw directly from him. Thunder and lightning are in their turn a manifestation of his power. Every fire which burns and every flame which shines has received its life from the sun. And when two armies are hurled together with a crash, each charge of cavalry, each shock between two army corps, is nothing else but the misuse of mechanical force from the same star. The sun comes to us in the form of heat, he leaves us in the form of heat, but between his arrival and his departure he has given birth to the varied powers of our globe.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 3, p. 245. (A.)

3305. SUN THE SOURCE OF TERRESTRIAL LIFE—*Three Necessary Elements Supplied—Light, Heat, and Actinism.*—Our sun sends forth rays which supply three very different requirements of living creatures, animal and vegetable, peopling out earth. Without light, we should all before long perish miserably; and the sun's rays supply us with light. Without heat, we should be even more quickly destroyed; and the sun's rays provide ample supplies of heat. But besides light and heat, we require, directly and indirectly, that chemical action of the solar rays which has been called actinism. Without this action the air we breathe would be loaded before long with pestilential vapors, which would destroy the lives of men and animals; plants would wither, and presently die; the whole earth, in fact, would soon be the abode of death, as surely, tho perhaps not so quickly, as tho the sun had ceased to supply either light or heat. Now at present these three forms of energy are exerted in certain proportions admirably suited to our requirements. Dividing the solar rays according to the position they occupy with reference to the spectrum, we have from the red rays, and from dark rays beyond the red, the chief supply of heat; from the whole visible spectrum, but chiefly from the yellow portion, comes the supply of light; and lastly, the violet rays and the dark rays beyond the violet afford the chief supply of actinism.—PROCTOR *Our Place among Infinities*, p. 212. (L. G. & Co., 1897.)

3306. SUN'S CORONA YET A MYSTERY—*Limited Opportunities for Observation—Three-quarters of an Hour in Thirty Years.*—Our knowledge of the corona remains very incomplete, and if the most learned in such matters were asked what it was, he could probably answer truthfully, "I don't know."

This will not be wondered at when it is considered that as total eclipses come about every other year, and continue. one with another, hardly three minutes, an astronomer who should devote thirty years exclusively to the subject, never missing an eclipse in whatever quarter of the globe it occurred, would in that time have secured, in all, something like three-quarters of an hour for observation. Accordingly, what we know best about the corona is how it looks, what it is being still largely conjecture.—LANGLEY *New Astronomy*, ch. 2, p. 59. (H. M. & Co., 1896.)

3307. SUN'S HEAT PRODUCED BY CONCENTRATION—*Probable Continued Duration of Solar Light and Heat.*—For how many ages has the sun himself shone? On the hypothesis that the nebulous matter was originally of extreme tenuity has been calculated the quantity of heat which must have been produced by the fall of all those molecules towards the center to the condensation of which was due the birth of the solar system. Supposing the specific heat of the condensing mass was that of water, the heat of the condensation would be sufficient to produce an elevation of temperature of 28 millions of degrees centigrade (Helmholtz and Tyndall). It has been known for some time past that heat is but a mode of motion; it is an infinitesimal vi-

bratory motion of the atoms. We can now convert at will all motion into heat, and all heat into motion. The motion of condensation has sufficed, and more than sufficed, to produce the present temperature of the sun and the original temperature of all the planets. If that brilliant star continues to condense, as is probable, a condensation which would shorten its diameter by $\frac{1}{10000}$ of its present length would produce a quantity of heat sufficient to cover the loss by emission during two thousand years. At the present rate of emission the solar heat produced by the earlier condensation of its mass would still last for 20 millions of years.—FLAMMARION *Popular Astronomy*, bk. i, ch. 7, p. 75. (A.)

3308. SUN'S SURFACE PHOTOGRAPHED—*Under the Camera—Photograph Secures Details Invisible to the Eye—Openings in an Atmosphere of Vaporized Metal—Reality Surpassing Wildest Dream.*—The photograph has transported us already so near the sun's surface that we have seen details there invisible to the naked eye. . . . What we have called "spots" are indeed regions whose actual vastness surpasses the vague immensity of a dream, and it will not cause surprise that in them is a temperature which also surpasses greatly that of the hottest furnace. . . . The whole surface is composed largely of metals turned into vapor in this heat, and . . . if we could indeed drop our great globe itself upon the sun it would be dissipated as a snowflake.—LANGLEY *New Astronomy*, ch. 1, p. 19. (H. M. & Co., 1896.)

3309. "SUNNY FRANCE" BURIED UNDER ICE—*The Glacial Epoch.*—At the time of the maximum extension of the ice-sheet almost the whole of the Swiss lowland was buried, and the ice welled up against the flanks of the Jura to a height of 3,000 feet above the Lake of Neuchâtel, whence it extended northward to the neighborhood of Soleure. Along the present course of the Rhone it sent out a huge lobe far beyond the frontier of Switzerland, for erratics [scattered boulders] and other glacial deposits have been traced to within a few miles of Lyons. It is estimated that altogether the ancient glacier of the Rhone was not less than 270 miles in length.—BONNEY *Ice-work, Present and Past*, pt. i, ch. 1, p. 35. (A., 1896.)

3310. SUNSET MADE BEAUTIFUL BY DUST—Owing to the constant presence of air currents, arranging both the dust and vapor [in the atmosphere] in strata of varying extent and density, and of high or low clouds, which both absorb and reflect the light in varying degrees, we see produced all those wondrous combinations of tints and those gorgeous ever-changing colors which are a constant source of admiration and delight to all who have the advantage of an uninterrupted view to the west, and who are accustomed to watch for these not unfrequent exhibitions of Nature's kaleidoscopic color-painting. With every change in the altitude of the sun the display changes its character, and most of all when it has sunk below the horizon, and, owing to the more favorable angles, a larger quantity of the colored light is reflected toward us. Especially when there is a certain amount of cloud is this the case. These, so long as the sun was above the horizon, intercepted much of the light and color; but when the great luminary has passed away from our direct vision his light shines more directly on the under sides of all the clouds and air strata of different densities; a new and more brilliant light flushes the western sky, and a display of gorgeous, ever-changing tints occurs which are at once the delight of the beholder and the despair of the artist. And all this unsurpassable glory we owe to dust!—WALLACE *The Wonderful Century*, ch. 9, p. 75. (D. M. & Co., 1899.)

3311. SUNSET MERGING INTO SUNRISE—*Effect of Atmospheric Refraction—The Midnight Sun at Tornea.*—It is not necessary to go to the polar circle in order to see the sun not setting and grazing the horizon at midnight. At the sixty-sixth degree of latitude in Sweden and Finland we can enjoy this spectacle, so strange to us—the midnight sun. It has even become the fashion in recent years to make a voyage to Tornea, a little town on the frontiers of Russia and Sweden, on the Gulf of Bothnia, and to be present on June 21 on Mount Avasaxa, only 227 meters high, when the sun does not set at the summer solstice.—FLAMMARION *Popular Astronomy*, bk. i, ch. 2, p. 30. (A.)

3312. SUNSHINE, DECREASE OF, IN ENGLAND—*The Vine Once Freely Grown—The Dust from Manufactories Changing a Nation's Climate.*—Now, there is much evidence to show that there has been a considerable increase in the amount of cloud, and consequent decrease in the amount of sunshine, in all parts of our country. It is an undoubted fact that in the Middle Ages England was a wine-producing country, and this implies more sunshine than we have now. . . . Some years back one of our gardening periodicals obtained from gardeners of forty or fifty years' experience a body of facts clearly indicating a comparatively recent change of climate. It was stated that in many parts of the country, especially in the north, fruits were formerly grown successfully and of good quality in gardens where they cannot be grown now. . . . But an increase of cloud, and consequent diminution of sunshine, would produce just such a result; and this increase is almost certain to have occurred, owing to the enormously increased amount of dust thrown into the atmosphere as our country has become more densely populated, and es-

pecially owing to the vast increase of our smoke-producing manufactories. . . . When this fact is thoroughly realized we shall surely put a stop to such a reckless and wholly unnecessary production of injurious smoke and dust.—WALLACE *The Wonderful Century*, ch. 9, p. 84. (D. M. & Co., 1899.)

3313. SUNSHINE, DURATION OF—*A Sunshine Autograph.*—For determining the duration of sunshine use is made of a simple apparatus called the sunshine autograph. Its common form is that of a ball of clear glass set up free, which collects the sun's rays like a burning glass, burning an index in a paper strip fastened behind the globe if the sunshine is bright enough. Since the paper strip is divided into hours it can be easily read when and how long the sun has been shining upon the apparatus. If the duration of sunshine thus obtained is compared with the length of day, the actual with the possible number of sunny hours, we obtain a number that in fact not only announces during what fraction of the hours of the day the sun was uncovered, but which harmonizes very well with the estimates of the entire cloud-covering. Many an important deduction concerning the thriving as well as the possibility of the improvement of plants, grapes, fruits, beets, etc., for whose development sunshine is particularly important, can be thus derived.—BÖRNSTEN *Leitfaden der Wetterkunde, 1901*, p. 58. (Translated for *Scientific Side-Lights.)*

3314. SUN-SPOTS EASILY SEEN—*Overlooked by Minds Unprepared to Recognize Them.*—An object of this size [30,000 miles] upon the sun's surface can easily be seen without a telescope when the brightness is reduced either by clouds, or nearness to the horizon, or by the use of a shade-glass. At the transit of Venus, in 1882, every one saw the planet readily without telescopic aid. Her apparent diameter was about 67″ at the time, which is equivalent to about 31,000 miles on the solar surface. Probably a very keen eye would detect a spot measuring not more than 23,000 or 24,000 miles.

Hardly a year passes, at times when spots are numerous, without furnishing several as large as this, so that it is rather surprising than otherwise that we have not a greater number of sun-spot records in the pretelescopic centuries. The explanation probably lies in two things: the sun is too bright to be often or easily looked at, and when spots were seen they would be likely to be taken for optical illusions rather than realities.—YOUNG *The Sun*, ch. 4, p. 27. (A., 1898.)

3315. SUN-SPOTS, SUPPOSED APERTURES IN SOLAR CLOUDS—*Herschel's Theory.*—Sir William Herschel, reasoning from terrestrial analogies, was led to look on the spot cavities as apertures through a double layer of clouds. He argued that were the solar photosphere of any other nature, it would be past comprehension that vast openings should form in it, to remain open for months before they close up again. . . . And because the solar spots present two distinct varieties of light, the faint penumbra and the dark umbra or nucleus, Herschel saw the necessity of assuming that there are two beds of clouds, the outer self-luminous and constituting the true solar photosphere, the inner reflecting the light received from the outer layer, and so shielding the real surface of the sun from the intense light and heat which it would otherwise receive.—PROCTOR *Other Worlds than Ours*, ch. 2, p. 36. (Burt.)

3316. SUPERFICIALITY OF MATERIALISM—*Science Does Not Include Philosophy—Eternal Problems behind Phenomena.*—Nothing is more common than to find men who may be trusted thoroughly on the facts of their own science, who cannot be trusted for a moment on the place which those facts assume in the general system of truth. Philosophy must include science; but science does not necessarily include philosophy. There are, and there always have been, some special misconceptions connected with the prosecution of physical research. It is, however, on the surface of things, rather than below it, that the suggestions of materialism lie thickest to the eye. They abound among the commonest facts which obtrude themselves on our attention in Nature and in human life. When the bursting of some small duct of blood upon the brain is seen to destroy in a moment the mind of man, and to break down all the powers of his intellect and his will, we are in presence of a fact whose significance cannot be increased by a million of other facts analogous in kind. Yet on every fresh discovery of a few more such facts there is generally some fresh outbreak of old delusions respecting the forms and the laws of matter as the supreme realities of the world. But when the new facts have been looked at a little longer it is always seen that they take their place with others which have been long familiar, and the eternal problems which lie behind all natural phenomena are seen to be unaffected and unchanged. Like the most distant of the fixed stars, they have no parallax.—ARGYLL *Reign of Law*, ch. 2, p. 68. (Burt.)

3317. SUPERNATURAL, THE, VS. THE SUPERHUMAN—*True and False Views of Law—Classification Is Not Explanation.*—Theological and philosophical writers frequently use the supernatural as synonymous with the superhuman. But of course this is not the sense in which any one can have any difficulty in believing in it. The powers and works of Nature are all superhuman—more than man can account for in their origin—more than he can resist in their energy—more than he can understand

in their effects. This, then, cannot be the sense in which so many minds find it hard to accept the supernatural; nor can it be the sense in which others cling to it as of the very essence of their religious faith. What, then, is that other sense in which the difficulty arises? Perhaps we shall best find it by seeking the idea which is competing with it, and by which it has been displaced. It is the natural which has been casting out the supernatural—the idea of natural law—the universal reign of a fixed order of things. This idea is a product of that immense development of the physical sciences which is characteristic of our time. We cannot read a periodical, or go into a lecture-room, without hearing it expressed. Sometimes, but rarely, it is stated with accuracy, and with due recognition of the limits within which law can be said to comprehend the phenomena of the world. But generally it is expressed in language vague and hollow, covering inaccurate conceptions, and confounding under common forms of expression ideas which are essentially distinct. The mere ticketing and orderly assortment of external facts is constantly spoken of as if it were in the nature of explanation, and as if no higher truth in respect to natural phenomena were to be attained or desired.—ARGYLL *Reign of Law*, ch. 1, p. 2. (Burt.)

3318. SUPERSTITION ACCOUNTING FOR THE FROZEN MAMMOTH—The inhabitants of Siberia seem to be familiar with this animal, which they designate by the name of mammoth, while naturalists call it *Elephas primigenius.* The circumstance that they abound in the frozen drift of the great northern plain of Asia, and are occasionally exposed in consequence of the wearing of the large rivers traversing Siberia, has led to the superstition among the Tongouses that the mammoths live underground, and die whenever, on coming to the surface, the sunlight falls upon them.—AGASSIZ *Geological Sketches*, ser. i, ch. 7, p. 183. (H. M. & Co., 1896.)

3319. SUPERSTITION ASCRIBES INUNDATIONS TO ARRIVAL OF SHIPS—In Kotzebue's "Voyage" there are accounts of islands, both in the Caroline and Marshall Archipelagoes, which have been partly washed away during hurricanes; and Kadu, the native who was on board one of the Russian vessels, said "he saw the sea at Radack rise to the feet of the coconut-trees; but it was conjured in time. . . . According to a tradition which was communicated to Captain Fitz Roy, it is believed in the Low Archipelago that the arrival of the first ship caused a great inundation which destroyed many lives.—DARWIN *Coral Reefs*, ch. 5, p. 129. (A., 1900.)

3320. SUPERSTITION AS TO AURORA BOREALIS—*Armies Seen Battling in the Sky.*—Pliny, the naturalist ("Naturalis Historia," ii, 26, 27, 33, and 57), says: "There are seen in the heaven (and nothing is more terrible for trembling mortals) blood-colored flames which afterwards fall upon the earth, as it happened in the third year of the hundred and seventh Olympiad, when King Philip ruled over Greece. . . . It is said that at the time of the wars of the Cimbri, and also often before and since, the clashing of arms and the sound of trumpets were heard in the sky. But in the third consulate of Marius the dwellers in Ameria and Tuderta saw in the heavens two armies rushing one against the other from the east and from the west; that of the west was defeated. The heaven itself caught fire: this is no extraordinary thing, and it has often been seen when the clouds are exposed to great heat."

In this quotation from Pliny we find for the first time the trace of that popular superstition which obtained almost down to our own day, and which attributed the great auroras to armies combating in the sky.—ANGOT *Aurora Borealis*, ch. 1, p. 3. (A., 1897.)

3321. SUPERSTITION AS TO PORTRAITS—*Life Shown in Picture Thought to Be Taken Away from Original.*—The redskins are not altogether deficient in art, being able to make rude carvings, and to trace equally rude drawings on their wigwams, robes, etc.; but about portraits they have some curious ideas. They think that an artist acquires some mysterious power over any one whose likeness he may have taken; and on one occasion, when annoyed by some Indians, Mr. Kane got rid of them at once by threatening to draw any one who remained. Not one ventured to do so. If the likeness is good, so much the worse; it is, they fancy, half alive—at the expense of the sitter. So much life, they argue, could only be put in the picture by taking it away from the original. Again they fancy that if the picture were injured, by some mysterious connection the original would suffer also.—AVEBURY *Prehistoric Times*, ch. 14, p. 504. (A., 1900.)

3322. SUPERSTITION CLOUDS TRIUMPH OF SCIENTIST—*A Trial for Witchcraft.*—The figurative and poetical myths of the Pythagorean and Platonic pictures of the universe, changeable as the fancy from which they emanated, may still be traced partially reflected in Kepler; but while they warmed and cheered his often saddened spirit, they never turned him aside from his earnest course, the goal of which he reached in the memorable night of the 15th of May, 1618, twelve years before his death. . . . "On the 8th of March, 1618, it occurred to Kepler, after many unsuccessful attempts, to compare the squares of the times of revolution of the planets with the cubes of the mean distances; but he made an error in his calculations, and rejected this idea. On the 15th of May, 1618, he again reverted to it, and calculated correctly. The third law

of Kepler was now discovered." This discovery and those related to it coincide with the unhappy period when this great man, who had been exposed from early childhood to the hardest blows of fate, was striving to save from the torture and the stake his mother, who, at the age of seventy years, in a trial for witchcraft, which lasted six years, had been accused of poison-mixing, inability of shedding tears, and of sorcery. The suspicion was increased from the circumstance that her own son, the wicked Christopher Kepler, a worker in tin, was her accuser, and that she had been brought up by an aunt who was burned at Weil as a witch.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 314. (H., 1897.)

3323. SUPERSTITION DEFEATING KINDNESS—*The Emperor of China Buries a Burning-glass.*—It is said that the Emperor of China, when he got his lens [a three-foot burning-glass, made at great expense, and sent by the English government as a present to the Chinese monarch], was much alarmed by it, as being possibly sent him by the English with some covert design for his injury. By way of a test, a smith was ordered to strike it with his hammer; but the hammer rebounded from the solid glass, and this was taken to be conclusive evidence of magic in the thing, which was immediately buried, and probably is still reposing under the soil of the Celestial Flowery Kingdom. —LANGLEY *New Astronomy*, ch. 4, p. 103. (H. M. & Co., 1896.)

3324. SUPERSTITION, EFFECTS OF—*Historic Eclipses Have Affected Believers in Their Malign Influence.*—History relates a crowd of memorable acts on which eclipses have had the greatest influence. Alexander, before the battle of Arbela, expected to see his army routed by the appearance of a phenomenon of this kind. The death of the Athenian general, Nicias, and the ruin of his army in Sicily, with which the decline of the Athenians commenced, had for their cause an eclipse of the moon. We know how Christopher Columbus, with his little army, threatened with death by famine at Jamaica, found means of procuring provisions from the natives by depriving them in the evening of the light of the moon. The eclipse had scarcely commenced when they supplied him with food. This was the eclipse of March 1, 1504, observed in Europe at Ulm by Stoffer, and at Nuremberg by Bernard Walter, and which happened at Jamaica at 6 o'clock in the evening. We need not relate other facts of this nature, in which history abounds, and which are known to every one.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 9, p. 181. (A.)

3325. SUPERSTITION FOUNDS ON NATURAL PHENOMENON—*The "Fairy Rings."*—Several low forms of plant life, such as *Marasmius oreades, Spathularia flavida*, and some of the puffballs, start in isolated spots in the grass of a lawn or pasture, and spread each year from a few inches to a foot or more in every direction, usually in the form of a circle; at the end of fifteen years some of these circles acquire a diameter of fifteen to twenty feet or more. These are known as fairy rings. Before science dispelled the illusion they were believed to have been the work of witches, elves, or evil spirits, from which arose the name.—BEAL *Seed Dispersal*, ch. 2, p. 4. (G. & Co., 1898.)

3326. SUPERSTITION IN AVOIDING SUPERSTITION—*Danger of Undue Recoil.*—Superstition, without a veil, is a deformed thing; for as it addeth deformity to an ape to be so like a man, so the similitude of superstition to religion makes it the more deformed; and as wholesome meat corrupteth to little worms, so good forms and orders corrupt into a number of petty observances. There is a superstition in avoiding superstition, when men think to do best if they go furthest from the superstition formerly received; therefore care would be had that (as it fareth in ill purgings) the good be not taken away with the bad, which commonly is done.—BACON *Essays*, essay 17, *Of Superstition*, p. 63. (W. L. A.)

3327. SUPERSTITION, INDICATIONS OF, IN LOWER ANIMALS—*Fear as a Result of Intellectual Confusion—Dog Terrified by Mystery.*—It produces a strange emotional "curdle" in our blood to see a process with which we are familiar deliberately taking an unwonted course. Any one's heart would stop beating if he perceived his chair sliding unassisted across the floor. The lower animals appear to be sensitive to the mysteriously exceptional as well as ourselves. My friend, Professor W. K. Brooks, of the Johns Hopkins University, told me of his large and noble dog being frightened into a sort of epileptic fit by a bone being drawn across the floor by a thread which the dog did not see. Darwin and Romanes have given similar experiences.—JAMES *Psychology*, vol. ii, ch. 24, p. 419. (H. H. & Co., 1899.)

3328. SUPERSTITION, ITS EXPLANATION OF SCIENTIFIC FACT—At the place where we slept [11,000 feet up in the Andes] water necessarily boiled, from the diminished pressure of the atmosphere, at a lower temperature than it does in a less lofty country, the case being the converse of that of a Papin's digester. Hence the potatoes, after remaining for some hours in the boiling water, were nearly as hard as ever. The pot was left on the fire all night, and next morning it was boiled again, but yet the potatoes were not cooked. I found out this by overhearing my two companions [Chileans] discussing the cause; they had come to the simple conclusion "that the cursed pot (which was a new one) did not choose to boil potatoes."—DARWIN *Naturalist's Voyage around the World*, ch. 15, p. 323. (A., 1898.)

3329. SUPERSTITION PREVENTING SCIENTIFIC STUDY—*Science Thought to Tempt to Witchcraft.*—In . . . ages so inimical to intellectual culture, when Christianity was diffused among the Germanic and Celtic nations, who had previously been devoted to the worship of Nature, and had honored under rough symbols its preserving and destroying powers, intimate intercourse with Nature, and a study of its phenomena, were gradually considered suspicious incentives to witchcraft. This communion with Nature was regarded in the same light as Tertullian, Clement of Alexandria, and almost all the older fathers of the church had considered the pursuit of the plastic arts. In the twelfth and thirteenth centuries the Councils of Tours (1163) and of Paris (1209) interdicted to monks the sinful reading of works on physics. Albertus Magnus and Roger Bacon were the first who boldly rent asunder these fetters of the intellect, and thus, as it were, absolved Nature, and restored her to her ancient rights.—HUMBOLDT *Cosmos*, vol. ii, pt. i, p. 43. (H., 1897.)

3330. SUPPORT FOR TREE-CLIMBER—*Perfect Grasp of Branches—The Monkey's Prehensile Tail.*—In the spider monkeys, the woolly monkeys, and the howling monkeys, the undersurface of the terminal portion of the tail is naked, so that it can be very closely applied to any surface with which it is in contact. The tail itself is a very powerful organ, and is capable of curling its own end so firmly round an object that the animal's whole body can thus be safely suspended. A tail of this kind is called a "prehensile tail." Not every American monkey has it, but no monkey which is not American possesses anything of the kind. Its possession must greatly add to the security and ease of locomotion of any forest-dwelling beast.—MIVART *Types of Animal Life*, ch. 1, p. 5. (L. B. & Co., 1893.)

3331. SUPREMACY COVETED IN A MAN'S CHOSEN FIELD—*Shame of Surpassing All but One.*—I, who for the time have staked my all on being a psychologist, am mortified if others know much more psychology than I. But I am contented to wallow in the grossest ignorance of Greek. My deficiencies there give me no sense of personal humiliation at all. Had I "pretensions" to be a linguist it would have been just the reverse. So we have the paradox of a man shamed to death because he is only the second pugilist or the second oarsman in the world. That he is able to beat the whole population of the globe minus one is nothing; he has "pitted" himself to beat that one, and as long as he doesn't do that nothing else counts. He is to his own regard as if he were not, indeed he is not.—JAMES *Psychology*, vol. i, ch. 10, p. 310. (H. H. & Co., 1899.)

3332. SUPREMACY OF MIND—*Newton—Scientific Fame Surpassing That of Warriors and Kings.*—There are, perhaps, no two sets of human beings who comprehend less the movements, and enter less into the cares and concerns, of each other, than the wide and busy public on the one hand, and on the other those men of close and studious retirement whom the world never hears of, save when, from their thoughtful solitude, there issues forth some splendid discovery to set the world on a gaze of admiration. Then will the brilliancy of a superior genius draw every eye towards it, and the homage paid to intellectual superiority will place its idol on a loftier eminence than all wealth or than all titles can bestow, and the name of the successful philosopher will circulate, in his own age, over the whole extent of civilized society, and be borne down to posterity in the characters of ever-enduring remembrance; and thus it is that when we look back on the days of Newton we annex a kind of mysterious greatness to him, who, by the pure force of his understanding, rose to such a gigantic elevation above the level of ordinary men, and the kings and warriors of other days sink into insignificance around him, . . . and, while all the vulgar grandeur of other days is now moldering in forgetfulness, the achievements of our great astronomer are still fresh in the veneration of his countrymen, and they carry him forward on the stream of time, with a reputation ever gathering, and the triumphs of a distinction that will never die.—CHALMERS *Astronomical Discourses*, p. 44. (R. Ct., 1848.)

3333. SURPRISE OF AERONAUT—*Falling Stone Follows Balloon—Communication of Motion.*—When we drop a stone from the top of the mast of a ship in motion it falls exactly at the foot of the mast, just as if the ship were at rest. The motion of the vessel is communicated to the mast, to the stone, and to everything on the floating abode; there is nothing but the resistance of the liquid plain cleft by the ship which permits the passengers to perceive the motion. It is the same on the railway and in a balloon. But as the earth does not encounter any strange obstacle, there is absolutely nothing in Nature which can by its resistance, by its motion, or by its shock, enable us to perceive the motion. This motion is common to all terrestrial bodies; if they are raised in the air, they have received beforehand the motion of our globe, its direction and its velocity; and even when they are at the highest point of the atmosphere they continue to move as the earth does.

We verify the same law in a balloon. I remember myself one day passing over the town of Orleans. I had taken care to write a despatch addressed to the leading journal of that town, and I had expected when we arrived above a promenade to let it fall,

by affixing a stone for a counterpoise. What was my surprise to see this stone, while descending, suspended beneath the balloon as if it had slipped the length of a cord. The balloon sails rather fast. Instead of falling on the spot I had chosen, or even in the town, the despatch, following a diagonal, fell into the Loire. I had not reflected on one of the oldest questions of my bachelor's degree, the independence of simultaneous motions. Very fortunately the balloon, having crossed the Loire, had towards evening descended sufficiently near the earth to allow us to hail an inhabitant of the town, who was following the Orleans road, on his way home, seated in a cabriolet, which advanced at a slow pace. It was nightfall, and the Angelus was wafted from the village bells. Much surprised was this traveler on hearing himself hailed from the height of heaven. He seemed at first to believe neither his ears nor his eyes. But the horse was promptly stopped, and we had sufficient time to announce our passing, which next morning was published in the newspapers.—FLAMMARION *Popular Astronomy*, p. 58. (A.)

3334. SURPRISE OF A GREAT DISCOVERY—*Newton Discovers the Spectrum—Light Composite—Its Apparent Simplicity Delusive.*—In the rainbow a new phenomenon was introduced—the phenomenon of color. And here we arrive at one of those points in the history of science when great men's labors so intermingle that it is difficult to assign to each worker his precise meed of honor. Descartes was at the threshold of the discovery of the composition of solar light; but for Newton was reserved the enunciation of the true law. He went to work in this way: Through the closed window-shutter of a room he pierced an orifice and allowed a thin sunbeam to pass through it. The beam stamped a round white image of the sun on the opposite wall of the room. In the path of this beam Newton placed a prism, expecting to see the beam refracted, but also expecting to see the image of the sun, after refraction, still round. To his astonishment, it was drawn out to an image with a length five times its breadth. It was, moreover, no longer white, but divided into bands of different colors. Newton saw immediately that solar light was composite, not simple. His elongated image revealed to him the fact that some constituents of the light were more deflected by the prism than others, and he concluded, therefore, that white solar light was a mixture of lights of different colors, of different degrees of refrangibility.—TYNDALL *Lectures on Light*, lect. 1, p. 26. (A., 1898.)

3335. SURRENDER OF PRETENSIONS A RELIEF FROM STRAIN—Yonder puny fellow, . . . , whom every one can beat, suffers no chagrin about it, for he has long ago abandoned the attempt to "carry that line," as the merchants say, of self at all. With no attempt there can be no failure; with no failure no humiliation. So our self-feeling in this world depends entirely on what we back ourselves to be and do. It is determined by the ratio of our actualities to our supposed potentialities, a fraction of which our pretensions are the denominator and the numerator our success: thus

$$\text{Self-esteem} = \frac{\text{Success}}{\text{Pretensions}}.$$

Such a fraction may be increased as well by diminishing the denominator as by increasing the numerator. To give up pretensions is as blessed a relief as to get them gratified; and where disappointment is incessant and the struggle unending, this is what men will always do. The history of evangelical theology, with its conviction of sin, its self-despair, and its abandonment of salvation by works, is the deepest of possible examples, but we meet others in every walk of life.—JAMES *Psychology*, vol. i, ch. 10, p. 310. (H. H. & Co., 1899.)

3336. ——— ——— *Illusions Abandoned—Burdens Dropped.*—There is the strangest lightness about the heart when one's nothingness in a particular line is once accepted in good faith. All is not bitterness in the lot of the lover sent away by the final inexorable "No." Many Bostonians, *crede experto* (and inhabitants of other cities, too, I fear) would be happier women and men to-day if they could once for all abandon the notion of keeping up a Musical Self, and without shame let people hear them call a symphony a nuisance. How pleasant is the day when we give up striving to be young—or slender! Thank God! we say, those illusions are gone. Everything added to the Self is a burden as well as a pride. A certain man who lost every penny during our civil war went and actually rolled in the dust, saying he had not felt so free and happy since he was born.—JAMES *Psychology*, vol. i, ch. 10, p. 311. (H. H. & Co., 1899.)

3337. SURVIVAL NOT BY CHANCE—*Some Quality of the Organism Determines.—Variations Universal.*—Why do some live rather than others? If all the individuals of each species were exactly alike in every respect we could only say it is a matter of chance. But they are not alike. We find that they vary in many different ways. Some are stronger, some swifter, some hardier in constitution, some more cunning. An obscure color may render concealment more easy for some, keener sight may enable others to discover prey or escape from an enemy better than their fellows. Among plants the smallest differences may be useful or the reverse. The earliest and strongest shoots may escape the slug; their greater vigor may enable them to flower and seed earlier in wet autumn; plants best armed with spines or hairs may escape being devoured; those whose flowers are most conspicuous may be soonest fertilized by in-

sects. We cannot doubt that, on the whole, any beneficial variations will give the possessors of it a greater probability of living through the tremendous ordeal they have to undergo. There may be something left to chance, but on the whole the fittest will survive.—WALLACE *Darwinism*, ch. 1, p. 7. (Hum.)

3338. SURVIVAL OF THE FITTEST—*Fitness Is Fittedness—The Texas Bull and the Mosquito—The Prize-fighter and the Cripple—Social Compassion Makes a New Fitness for the Weak.*—The survival of the fittest, of course, does not mean the survival of the strongest. It means the survival of the adapted—the survival of the [one] most fitted to the circumstances which surround it. A fish survives in water when a leaking ironclad goes to the bottom, not because it is stronger, but because it is better adapted to the element in which it lives. A Texas bull is stronger than a mosquito, but in an autumn drought the bull dies, the mosquito lives. Fitness to survive is simply fittedness, and has nothing to do with strength or courage, or intelligence or cunning as such, but only with adjustments as fit or unfit to the world around. A prize-fighter is stronger than a cripple; but in the environment of modern life the cripple is cared for by the people, is judged fit to live by a moral world, while the pugilist, handicapped by his very health, has to conduct his own struggle for existence. Physical fitness here is actually a disqualification; what was once unfitness is now fitness to survive. As we rise in the scale the physical fitness of the early world changes to fitness of a different quality, and this law becomes the guardian of a moral order. In one era the race is to the swift, in another the meek inherit the earth. In a material world social survival depends on wealth, health, power; in a moral world the fittest are the weak, the pitiable, the poor. Thus there comes a time when this very law, in securing survival for those who would otherwise sink and fall, is the minister of moral ends.—DRUMMOND *Ascent of Man*, ch. 6, p. 209. (J. P., 1900.)

3339. ——— ——— *Natural Interference with.*—Apes that abstract a thorn from a wounded comrade, and protect the weak or wounded, defy the laws of the struggle for existence.—KOKEN *Die Vorwelt*, p. 635. (Translated for *Scientific Side-Lights.*)

3340. SURVIVAL OF WEAPON AS SYMBOL OF POWER—*The Mace Is the War-club of Primitive Man.*—Among the simplest of weapons is the thick stick or cudgel, which when heavier or knobbed passes into the club. Rude champions have delighted in the ferocious roughness of such a gnarled club as Hercules in the pictures carries on his shoulder, while others spent their leisure hours in elegant shaping and carving, like that of the South Sea Island clubs to be seen in museums. From savage through barbaric times the war-club lasted on into the Middle Ages of Europe, when knights still smashed helmets in with their heavy maces. Mostly used as a weapon, it only now and then appears in peaceful arts, as in the ribbed clubs with which the Polynesian women beat out bark cloth. It is curious to see how the rudest of primitive weapons, after its serious warlike use has ceased, survives as a symbol of power, when the mace is carried as emblem of the royal authority, and is laid on the table during the sitting of Parliament or the Royal Society.—TYLOR *Anthropology*, ch. 8, p. 184. (A., 1899.)

3341. SUSPENSE, EVIL HELD IN—*May Burst Forth Anew—Antiseptics vs. Germicides—Cold Merely Represses Bacteria.*—In a cold temperature, as a general rule, bacteria do not multiply with the same rapidity as at blood-heat. Within the limits of a moist perimeter the air is, to all intents and purposes, germ-free. Direct sunlight has a definitely germicidal effect in the course of time upon some of the most virulent bacteria we know. Here, then, are three examples of physical agents—low temperature, moist perimeter, sunlight—which, if strong enough in degree, or acting for a long enough period of time, become first antiseptics and then germicides. Yet for a limited period they have no injurious effect upon bacteria.—NEWMAN *Bacteria*, ch. 9, p. 323. (G. P. P., 1899.)

3342. SUSPENSE, IMPATIENCE OF—*Longing for Action of Some Kind.*—Certain motives are more or less constantly in play [in time of deliberation]. One of these is impatience of the deliberative state; or, to express it otherwise, proneness to act or to decide merely because action and decision are, as such, agreeable, and relieve the tension of doubt and hesitancy. Thus it comes that we will often take any course whatever which happens to be most vividly before our minds, at the moment when this impulse to decisive action becomes extreme. —JAMES *Psychology*, vol. ii, ch. 26, p. 529. (H. H. & Co., 1899.)

3343. SUSTENANCE STORED IN BODY FOR LONG FAST—*Summer Torpidity of Lemuroids.*—Certain small nocturnal lemuroids inhabit Madagascar. . . . They have also an interesting peculiarity of a temporary nature; this is their tendency to accumulate a quantity of fat in certain parts of the body, especially at the root of the tail, which becomes of an exceedingly large size. This peculiarity of structure is related to a peculiarity of habit, for during the dry season they retire into the holes of trees, coil themselves up, and pass the whole period in sleep, as bats with us hibernate in winter. When, with the advent of the rainy season, they rouse themselves again, their fat has disappeared, having

served to nourish them during their period of torpor.—MIVART *Types of Animal Life*, ch. 12, p. 343. (L. B. & Co., 1893.)

3344. SWIFTNESS OF EARTH'S REVOLUTION—*Man Like Dust on Flying Cannon-ball.*—In order to accomplish, as it does in 365¼ days, this immense distance round the sun our sphere is obliged to travel a distance of 2,544,000 kilometers [1,580,765.28 miles] a day, or 106,000 kilometers [65,865.22 miles] an hour, or 29 kilometers [18 miles] a second! This is an absolutely demonstrated mathematical fact. . . . We sail, then, in immensity with a velocity eleven hundred times quicker than that of an express train. . . . This velocity of our globe in its celestial orbit is seventy-five times swifter than that of a cannon-ball.

Upon this moving globe we live, almost in the same situation as grains of dust adhering to the surface of an enormous cannon-ball shot into immensity. * * * Sharing absolutely in all the motions of the globe, with all that surrounds us, we cannot perceive these motions, and we can only detect them from observations of the stars, which do not participate in the motion. Marvelous sidereal mechanism—the force which transports our planet is exercised without an effort, without friction, and without shocks in the midst of absolute silence in the eternal heavens. Smoother than the barge upon the limpid river, smoother than the gondola moving on the mirror of the Venetian canals, the earth glides majestically in its ideal orbit, showing no perceptible trace of the powerful force which guides it. Thus, but not with such perfection, glides the solitary balloon in the midst of the transparent air. How many times, entrusted to the car of the aerial ship, either during the bright hours of the day above the verdant fields, or in the darkness of night, with the melancholy light of the moon and stars—how many times have I compared the glorious course of the balloon in the atmosphere to that of the earth in space!—FLAMMARION *Popular Astronomy*, bk. i, ch. 1, p. 8. (A.)

3345. SWIFTNESS OF MOTION—*A Gnat's Wings—Corresponding Quickness of Perception.*—" A gnat's wings," says Mr. Spencer, " make ten or fifteen thousand strokes a second. Each stroke implies a separate nervous action. Each such nervous action or change in a nervous center is probably as appreciable by the gnat as is a quick movement of his arm by a man. And if this, or anything like this, is the fact, then the time occupied by a given external change, measured by many movements in the one case, must seem much longer than in the other case, when measured by one movement."—JAMES *Psychology*, vol. i, ch. 15, p. 639. (H. H. & Co., 1899.)

3346. SYMPATHY A GENUINE HUMAN IMPULSE—*Not a Result of Calculation.*—Sympathy is an emotion as to whose instinctiveness psychologists have held hot debate, some of them contending that it is no primitive endowment, but, originally at least, the result of a rapid calculation of the good consequences to ourselves of the sympathetic act. Such a calculation, at first conscious, would grow more unconscious as it became more habitual, and at last, tradition and association aiding, might prompt to actions which could not be distinguished from immediate impulses. It is hardly needful to argue against the falsity of this view. Some forms of sympathy, that of mother with child, for example, are surely primitive, and not intelligent forecasts of board and lodging and other support to be reaped in old age. Danger to the child blindly and instantaneously stimulates the mother to actions of alarm or defense. Menace or harm to the adult beloved or friend excites us in a corresponding way, often against all the dictates of prudence. It is true that sympathy does not necessarily follow from the mere fact of gregariousness. Cattle do not help a wounded comrade; on the contrary, they are more likely to despatch him. But a dog will lick another sick dog, and even bring him food; and the sympathy of monkeys is proved by many observations to be strong. In man, then, we may lay it down that the sight of suffering or danger to others is a direct exciter of interest, and an immediate stimulus, if no complication hinders, to acts of relief.—JAMES *Psychology*, vol. ii, ch. 24, p. 410. (H. H. & Co., 1899.)

3347. SYMPATHY AND KINDNESS AMONG APES—Here is a case which I myself witnessed at the Zoological Gardens, and published in the *Quarterly Journal of Science*, from which I now quote: " A year or two ago there was an Arabian baboon and an Anubis baboon confined in one cage, adjoining that which contained a dog-headed baboon. The Anubis baboon passed its hand through the wires of the partition, in order to purloin a nut which the large dog-headed baboon had left within reach—expressly, I believe, that it might act as a bait. The Anubis baboon very well knew the danger he ran, for he waited until his bulky neighbor had turned his back upon the nut with the appearance of having forgotten all about it. The dog-headed baboon, however, was all the time slyly looking round with the corner of his eye, and no sooner was the arm of his victim well within his cage than he sprang with astonishing rapidity and caught the retreating hand in his mouth. The cries of the Anubis baboon quickly brought the keeper to the rescue, when, by dint of a good deal of physical persuasion, the dog-headed baboon was induced to leave go his hold. The Anubis baboon then retired to the middle of his cage, moaning piteously, and holding the injured hand against his chest while he rubbed it with the other one. The Arabian baboon now approached him from the

top part of the cage, and while making a soothing sound very expressive of sympathy, folded the sufferer in his arms—exactly as a mother would her child under similar circumstances. It must be stated, also, that this expression of sympathy had a decidedly quieting effect upon the sufferer, his moans becoming less piteous so soon as he was enfolded in the arms of his comforter; and the manner in which he laid his cheek upon the bosom of his friend was as expressive as anything could be of sympathy appreciated. This really affecting spectacle lasted a considerable time, and while watching it I felt that, even had it stood alone, it would in itself have been sufficient to prove the essential identity of some of the noblest among human emotions with those of the lower animals."—ROMANES *Animal Intelligence*, ch. 17, p. 474. (A., 1899.)

3348. SYMPATHY, HINDRANCES TO—*Cruelty of Mobs.*—Sympathy is peculiarly liable to inhibition from other instincts which its stimulus may call forth. The traveler whom the good Samaritan rescued may well have prompted such instinctive fear or disgust in the priest and Levite who passed in front of him, that their sympathy could not come to the front. Then, of course, habits, reasoned reflections, and calculations may either check or reenforce one's sympathy, as may also the instincts of love or hate, if these exist, for the suffering individual. The hunting and pugnacious instincts, when aroused, also inhibit our sympathy absolutely. This accounts for the cruelty of collections of men hounding each other on to bait or torture a victim. The blood mounts to the eyes, and sympathy's chance is gone.—JAMES *Psychology*, vol. ii, ch. 24, p. 411. (H. H. & Co., 1899.)

3349. SYMPATHY WITH PICTURED EMOTION—As emotions are described in novels, they interest us, for we are made to share them. We have grown acquainted with the concrete objects and emergencies which call them forth, and any knowing touch of introspection which may grace the page meets with a quick and feeling response.—JAMES *Psychology*, vol. ii, ch. 25, p. 448. (H. H. & Co., 1899.)

3350. SYMPATHY WITH STORM AND DARKNESS—*The Wild Beast's Response to the Terrible in Nature.*—If an African lion is to be seen in his glory, he must be looked at by the lightning's glare. It is amid tempest and gloom that the full proportions of his nature come forth. So with this lion of another world [a captive puma]. Many a time in the course of those nightly interviews . . . he roused himself from an intense contemplation of his companion, disturbed by thunder and the tumult without. Then while the wind blew unequally, roared through swaying branches, or mourned around the walls that shut him in, he quickened under the influence of overtones in Nature which human beings cannot hear. Storm and darkness wrought upon him as they will not do upon man. Beyond what was visible or audible there was something that came from within himself; something that wove "the waste fantasies" of his dreams together, and gave character and purpose to ideation. He showed it in profoundly suggestive pantomime. But what "air-drawn" shapes were followed with those long, swift, soft yet heavy steps, on what his eyes were fixed, what feelings and fancies engrossed and transfigured him, gave that fierce energy, and led him in their train, are unknowable. They had no voice, but only with mute motions pointed backward to a past in which humanity shared no part, and which it cannot explore.—PORTER *Wild Beasts*, p. 290. (A., 1894.)

3351. SYNTHESIS, CHEMICAL—*Building Greater than Destruction—Vital Products Chemically Produced.*—One of the marked features of modern chemistry has been in the widening of the field of synthetic research. The building of a molecule requires far more skill than its destruction, and therefore, as the knowledge of chemical principles has advanced, and as the skill of the analyst has increased, it has been possible to put together the chemical elements into increasingly more complex and more valuable forms. Following out researches of this kind, the chemist has been able to produce by synthesis hundreds of compounds which a quarter of a century ago were supposed to be exclusively formed by the activity of the so-called vital forces.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 28).

3352. SYSTEM, COPERNICAN—*Humble Worker Solves Mystery of Universe—Patience and Exactness of Science.*—The hypothesis of the earth's motion had been suggested long before his [Copernicus's] birth on this planet. This theory counted partisans in his time. But he—he did his work. He examined it with the patience of an astronomer, the rigor of a mathematician, the sincerity of a sage, and the mind of a philosopher. He demonstrated it in his works. Then he died without seeing it understood, and it was not till a century after his death that astronomy adopted it and popularized it by teaching it. However, Copernicus is really the author of the true system of the world, and his name will remain respected to the end of time.

This great man was neither potentate, prince, nor official personage, nor covered with titles more or less sonorous and more or less vain. He was a modest physician, the friend of humanity and the friend of science, consecrating his whole life to the study of Nature, nobly indifferent as well to fortune as to glory. He was the son of a Polish baker, and became by his own

labors the greatest man of his age. The physician became a priest, a physician of the soul, and the position of a canon assured to him the calm and tranquil life which he preferred. His uncle was a bishop, and was sometimes astonished that he should "lose his time" working at astronomy.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 1, p. 343. (A.)

3353. SYSTEMS MERELY ARTIFICIAL MUST PERISH—*The Linnean System of Botany.*—The botany of Linnæus, a purely artificial system, was a splendid contribution to human knowledge, and did more in its day to enlarge the view of the vegetable kingdom than all that had gone before. But all artificial systems must pass away. None knew better than the great Swedish naturalist himself that his system, being artificial, was but provisional. Nature must be read in its own light. And as the botanical field became more luminous the system of Jussieu and De Candolle slowly emerged as a native growth, unfolded itself as naturally as the petals of one of its own flowers, and forcing itself upon men's intelligence as the very voice of Nature, banished the Linnean system forever.—DRUMMOND *Natural Law in the Spiritual World*, int., p. 18. (H. Al.)

3354. SYSTEMS OF RELATED COMETS—*A Common Origin in Distant Space.*—The idea of cometary systems was first suggested by Thomas Clausen in 1831. It was developed by the acute inquiries of the late M. Hoek, director of the Utrecht Observatory, in 1865 and some following years. He found that in quite a considerable number of cases the paths of two or three comets had a common point of intersection far out in space, indicating with much likelihood a community of origin. This consisted, according to his surmise, in the disruption of a parent mass during its sweep round the star latest visited. Be this as it may, the fact is undoubted that numerous comets fall into groups, in which similar conditions of motion betray a preexistent physical connection.—CLERKE *History of Astronomy*, pt. ii, ch. 11, p. 438. (Bl., 1893.)

3355. TANGIBLE, THE, HELD TO BE THE REAL—*Objects Hurt or Help Only by Contact—Other Senses Are but Anticipatory Touch.*—Why do we thus so markedly select the *tangible* to be the real? Our motives are not far to seek. The tangible qualities are the least fluctuating. When we get them at all we get them the same. The other qualities fluctuate enormously as our relative position to the object changes. Then, more decisive still, the tactile properties are these most intimately connected with our weal or woe. A dagger hurts us only when in contact with our skin, a poison only when we take it into our mouths, and we can only use an object for our advantage when we have it in our muscular control. It is as tangibles, then, that things concern us most; and the other senses, so far as their practical use goes, do but warn us of what tangible things to expect. They are but organs of anticipatory touch, as Berkeley has with perfect clearness explained.—JAMES *Psychology*, vol. ii, ch. 21, p. 306. (H. H. & Co., 1899.)

3356. TASKS, CONTRASTED, FOR MAN AND WOMAN—*Woman's Bias toward the Domestic Life.*—Among primitive peoples, as largely in modern times, "The tasks which demand a powerful development of muscle and bone, and the resulting capacity for intermittent spurts of energy, involving corresponding periods of rest, fall to the man; the care of the children and all the various industries which radiate from the hearth, and which call for an expenditure of energy more continuous, but at a lower tension, fall to the woman." [Havelock Ellis, "Man and Woman," p. 2.] Whether this or any theory of the origin of sex be proved or unproved, the fact remains, and is everywhere emphasized in Nature, that a certain constitutional difference exists between male and female, a difference inclining the one to a robuster life, and implanting in the other a certain mysterious bias in the direction of what one can only call the womanly disposition.*—DRUMMOND *Ascent of Man*, ch. 7, p. 256. (J. P., 1900.)

3357. TASKS INCREASED WITH POWER—*New Problems of Astronomy.*—The means at the disposal of astronomers have not multiplied faster than the tasks imposed upon them. Looking back to the year 1800, we cannot fail to be astonished at the change. The comparatively simple and serene science of the heavenly bodies known to our predecessors, almost perfect so far as it went, incurious of what lay beyond its grasp, has developed into a body of manifold powers and parts, each with its separate mode and means of growth, full of strong vitality, but animated by a restless and unsatisfied spirit, haunted by the sense of problems unsolved, and tormented by conscious impotence to sound the immensities it perpetually confronts.—CLERKE *History of Astronomy*, pt. ii, ch. 13, p. 526. (Bl., 1893.)

3358. TASTE AMONG PRIMITIVE WOMEN—*Early Needle and Thread—Geometric Patterns.*—The first sewing-machine was a needle or bodkin of bone, with dainty sinew thread from the leg of the antelope, and for thimble a little leather cap over the ends of the fingers. Coarse, indeed, the apparatus, but the hand was deft, the eye was true, the sense of beauty was there, and so that needlewoman of long ago

* —— "but this is fixt
As are the roots of earth and base of all,
Man for the field and woman for the hearth;
Man for the sword and for the needle she;
Man with the head and woman with the heart."
—TENNYSON *Princess*, can. v, st. 16, l. 9.

wrought in fur from the mammals, feathers from the birds, grasses from the fields, shells from the sea, wings from the beetle, and skins of snakes, with tasteful geometric figures. You do err who think those ancient needlewomen had no taste. It would be hard to invent a pattern now that was unfamiliar to them.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891, Proceedings of the Congress*, p. 408).

3359. TASTE IN MUSIC, PROGRESS OF—*Greeks and Japanese—Handel—Beethoven—Wagner.*—The pains and pleasures of tones, tastes, and smells, altho still immediately sensuous, are becoming, as development goes on, more and more matters of determination according to ideal standards. The ear of the Greeks scarcely tolerated as agreeable the "imperfect consonances" of the major and minor third. But Handel accepted "fourths," Beethoven "fifths," and the modern Wagnerian music pleases many lovers of music, altho tolerating the widest range of discords. Some nations, whose music is quite undeveloped (notably, for example, the Japanese), find intervals agreeable which are intolerable to us, apparently because of the association of the tones with the sad, weird sounds of Nature, so "consonant" with the national tone of feeling.—LADD *Psychology*, ch. 10, p. 198. (S., 1899.)

3360. TASTE ROUSES DIGESTIVE ORGANS—*Function of the Palate—Unspoiled Appetite a Guide to Nutrition—Nature's Chemistry.*—It would seem that gelatin alone, altho containing the elements required for nutrition, requires something more to render it digestible. We shall probably be not far from the truth if we picture it to the mind as something too smooth, too neutral, too inert, to set the digestive organs at work, and that it therefore requires the addition of a decidedly sapid something that shall make these organs act. I believe that the proper function of the palate is to determine our selection of such materials; that its activity is in direct sympathy with that of all the digestive organs, and that if we carefully avoid the vitiation of our natural appetites, we have in our mouths and the nervous apparatus connected therewith a laboratory that is capable of supplying us with information concerning some of the chemical relations of food which is beyond the grasp of the analytical machinery of the ablest of our scientific chemists.—WILLIAMS *Chemistry of Cookery*, ch. 4, p. 40. (A., 1900.)

3361. TEA IN CHINA—*A Nation Supplied with Sterilized Water.*—In the country which over all others combines a very large population with a very small allowance of cleanliness, the ordinary drink of the people is boiled water flavored by an infusion of leaves. These people, the Chinese, seem, in fact, to have been the inventors of boiled-water beverages. Judging from travelers' accounts of the state of the rivers, rivulets, and general drainage and irrigation arrangements of China, its population could scarcely have reached its present density if Chinamen were drinkers of raw instead of cooked water. This is especially remarkable in the case of such places as Canton, where large numbers are living afloat on the mouths of sewage-laden rivers or estuaries. The ordinary every-day domestic beverage is a weak infusion of tea, made in a large teapot, kept in a padded basket to retain the heat. The whole family is supplied from this reservoir. The very poorest drink plain hot water, or water tinged by infusing the spent tea-leaves rejected by their richer neighbors.—WILLIAMS *Chemistry of Cookery*, ch. 2, p. 13. (A., 1900.)

3362. TEACHABLENESS DISTINGUISHES HUMANITY—*Man Can Learn.*—It is not too much to say that the difference between man and all other living creatures, in respect of teachableness, progressiveness, and individuality of character, surpasses all other differences of kind that are known to exist in the universe.—FISKE *Destiny of Man*, ch. 6, p. 56. (H. M. & Co., 1900.)

3363. TEACHING NOT A SUBSTITUTE FOR SEEING—*Instruction about Light Given to the Blind.*—In training-institutions for the blind they teach the pupils as much about light as in ordinary schools. Reflection, refraction, the spectrum, the ether-theory, etc., are all studied. But the best taught born-blind pupil of such an establishment yet lacks a knowledge which the least instructed seeing baby has. They can never show him what light is in its "first intention"; and the loss of that sensible knowledge no book-learning can replace.—JAMES *Psychology*, vol. ii, ch. 17, p. 4. (H. H. & Co., 1899.)

3364. TELEGRAPH, ELECTRIC—*Foreshadowed in the Animal Economy.*—We must look for the soul in the brain as the only province in the body known to possess sensibility. Just as the center station of our post-office is in communication with the uttermost boundaries of our monarchy by means of its gigantic spider-web of copper wires, so the soul in its office, the brain, is ceaselessly receiving messages through its telegraph wires, the nerves, from all of the limits of its kingdom, the body, and distributing commands in all directions to its officials, the muscles.

As he glances at the mute, indifferent wire, who can discern whether the message, trembling with lightning celerity along its course, is bringing news of a victory, or a stock quotation, or some unextinguishable disgrace to himself? Thus, no matter what storm may be raging within the nerves, they never change their external appearance, tho they deliver messages that vary a thousand-fold, or whether they carry from the instru-

ments of the senses to the brain, or return from the brain to the members out in the world. And just as the brain cannot distinguish from which point in any thread of perception the news of pain has arrived, since a knock on the elbow may be felt in the hand, so the telegraph operator cannot know from what station a despatch is being sent until the name of that station is announced. And if at any point the wire is destroyed, tho a mob may riot or a run of ice threaten to destroy, no officials will receive warning. And just so, if the nerves of sensation in a man's leg were paralyzed, the burning of his foot to ashes would not disturb his sleep any more than if that leg were of wood.

We see, then, that the miracle of our age, the electric telegraph, was prefigured long ago in the animal machine. But the similarity between the two kinds of apparatus, the nervous system and the electric telegraph, is still more profound. It is more than similarity; it is relationship, corresponding not merely in their effects, but also in their causes.—Du Bois-Reymond *Tierische Bewegung (a Lecture)*, in *Virchow und Holtzendorff's Sammlung wissenschaftlicher Vorträge.* (Translated for *Scientific Side-Lights.)*

3365. ——— ——— *Long Preparation for—Unity of the Host of Discoverers.*—The ancients discovered the electricity of amber; and Gilbert, in the year 1600, extended the discovery to other bodies. Then followed Boyle, Von Guericke, Gray, Canton, Du Fay, Kleist, Cunæus, and your own Franklin. But their form of electricity, tho tried, did not come into use for telegraphic purposes. Then appeared the great Italian Volta, who discovered the source of electricity which bears his name, and applied the most profound insight and the most delicate experimental skill to its development. Then arose the man who added to the powers of his intellect all the graces of the human heart, Michael Faraday, the discoverer of the great domain of magneto-electricity. Oersted discovered the deflection of the magnetic needle, and Arago and Sturgeon the magnetization of iron by the electric current. The voltaic circuit finally found its theoretic Newton in Ohm; while Henry, of Princeton, who had the sagacity to recognize the merits of Ohm while they were still decried in his own country, was at this time in the van of experimental inquiry.

In the works of these men you have all the materials employed at this hour, in all the forms of the electric telegraph. Nay, more; Gauss, the celebrated astronomer, and Weber, the celebrated natural philosopher, both professors in the University of Göttingen, wishing to establish a rapid mode of communication between the observatory and the physical cabinet of the university, did this by means of an electric telegraph. Thus, before your practical men appeared upon the scene, the force had been discovered, its laws investigated and made sure, the most complete mastery of its phenomena had been attained—nay, its applicability to telegraphic purposes demonstrated—by men whose sole reward for their labors was the noble excitement of research, and the joy attendant on the discovery of natural truth.—Tyndall *Lectures on Light*, lect. 6, p. 220. (A., 1893.)

3366. TELEPATHY — *Communication without Speech—A Possible New Step of Evolution.*—Is this the end? It is by no means likely. The mind is feeling about already for more perfect forms of human intercourse than telegraphed or telephoned words. As there was a stage in the ascent of man at which the body was laid aside as a finished product, and made to give way to mind, there may be a stage in the evolution of mind when its material achievements—its body—shall be laid aside and give place to a higher form of mind. Telepathy has already become a word, not a word for thought-reading or muscle-reading, but a scientific word. It means "the ability of one mind to impress, or to be impressed by another mind, otherwise than through the recognized channels of sense." By men of science, adepts in mental analysis, aware of all sources of error, armed against fraud, this subject is now being made the theme of exhaustive observation.—Drummond *Ascent of Man*, ch. 5, p. 183. (J. P., 1900.)

3367. TELEPHONE ANTICIPATES THE EYE—*Passage of Lightning Heard before Flash Is Seen.*—The sound produced in the telephone by lightning, even when so distant that only the flash can be seen in the horizon, and no thunder can be heard, is very characteristic—something like the quenching of a drop of molten metal in water, or the sound of a distant rocket; but the remarkable circumstance for us in this history is that this sound is always heard just before the flash is seen, showing that there is an inductive disturbance of the electricity overhead, due to the distant concentration preceding the disruptive discharge. Thus, on November 18, 1877, these peculiar sounds were heard in Providence, and the papers next morning explained them by reporting thunder-storms in Massachusetts. Sounds like those produced by lightning, but fainter, are almost always heard many hours before a thunder-storm actually breaks.—Fahie *Wireless Telegraphy*, p. 80. (D. M. & Co., 1900.)

3368. TELESCOPE EXTENDS DOMAIN OF HUMAN MIND—*Gives Mathematics Nobler Problems—Perception Reacts upon Thought.*—The transition from natural to telescopic vision which characterizes the first ten years of the seventeenth century was more important to astronomy (the knowledge of the regions of space) than the year 1492 (that of the discoveries of Co-

lumbus) in respect to our knowledge of terrestrial space. It not only infinitely extended our insight into creation, but also, besides enriching the sphere of human ideas, raised mathematical science to a previously unattained splendor by the exposition of new and complicated problems. Thus the increased power of the organs of perception reacts on the world of thought, to the strengthening of intellectual force and the ennoblement of humanity. To the telescope alone we owe the discovery in less than two and a half centuries of thirteen new planets, of four satellite systems (the four moons of Jupiter, eight satellites of Saturn, four or perhaps six of Uranus, and one of Neptune), of the sun's spots and faculæ, the phases of Venus, the form and height of the lunar mountains, the wintry polar zones of Mars, the belts of Jupiter and Saturn, the rings of the latter, the interior planetary comets of short periods of revolution, together with many other phenomena which likewise escape the naked eye. While our own solar system, which so long seemed limited to six planets and one moon, has been enriched in the space of 240 years with the discoveries to which we have alluded, our knowledge regarding successive strata of the region of the fixed stars has unexpectedly been still more increased. Thousands of nebulæ, stellar swarms, and double stars have been observed. The changing position of the double stars which revolve round one common center of gravity has proved, like the proper motion of all fixed stars, that forces of gravitation are operating in those distant regions of space, as in our own limited, mutually disturbing planetary spheres, . . . The astronomical knowledge of the solar system has gradually extended to that of a system of the universe.—HUMBOLDT *Cosmos*, vol. iii, p. 61. (H., 1897.)

3369. TEMPERAMENT DETERMINING ACTION—*A Wide-spread Belief—Incorporated in Language.*—The various words in use to characterize the different temperaments are highly instructive. They show the persistent and wide-spread impression that the lines are laid down, within which the development of the individual takes place, by some form of physical influence that operates upon the original "make-up" of the individual. When men believed in astrology they found in the determining power of the planets a reason why some were "Jovial," others "Saturnine," and still others "Mercurial" in temperament. When they more justly recognized the influence of the circulatory and digestive systems over every one's "temper" of mind, they came to speak of the "sanguine" (or "full-blooded") man, of the "choleric" (or "full of bile") man, of the "melancholic" (or "full of black bile") man, and of the "phlegmatic" (or "full-phlegmed") man. Thus, in Shakespeare's "King John" we read:

> Or if that surly spirit, melancholy,
> Had baked thy blood and made it heavy thick, which
> Else, runs tickling up and down the veins.

—LADD *Psychology*, ch. 27, p. 649. (S., 1899.)

3370. TEMPERANCE OF SAVAGE WOMEN—A remarkable result of abstinence and morality is the fact that neither in America nor in Africa nor in the Indo-Pacific were women guilty of indulgence in the native forms of intoxication. In the New Hebrides and elsewhere Turner found that the women and girls were total abstainers from drinking kava. "Drunkenness," says Dodge, "is not a female vice. In all my experience I have never seen a drunken Indian woman." Similar testimony could be gathered concerning beer-drinking in Africa. —MASON *Woman's Share in Primitive Culture*, ch. 10, p. 235. (A., 1894.)

3371. TEMPERATURE IN EUROPE AND AMERICA—*Land a Conductor of Cold—Ocean Tends to Produce Uniform Climate.*—On comparing the two continents of Europe and America, it is found that places in the same latitudes have sometimes a mean difference of temperature amounting to 11°, or even in a few cases to 17° F.; and some places on the two continents, which have the same mean temperature, differ from 7° to 17° in latitude. Thus, Cumberland House, in North America, having the same latitude (54° N.) as the city of York in England, stands on the isothermal line of 32°, which in Europe rises to the North Cape, in lat. 71°, but its summer heat exceeds that of Brussels or Paris. The principal cause of greater intensity of cold in corresponding latitudes of North America, as contrasted with Europe, is the connection of America with the polar circle, by a large tract of land, some of which is from three to five thousand feet in height; and, on the other hand, the separation of Europe from the arctic circle by an ocean. The ocean has a tendency to preserve everywhere a mean temperature, which it communicates to the contiguous land, so that it tempers the climate, moderating alike an excess of heat or cold. The elevated land, on the other hand, rising to the colder regions of the atmosphere, becomes a great reservoir of ice and snow, arrests, condenses, and congeals vapor, and communicates its cold to the adjoining country. For this reason, Greenland, forming part of a continent which stretches northward to the 82d degree of latitude, experiences under the 60th parallel a more rigorous climate than Lapland under the 72d parallel.—LYELL *Principles of Geology*, bk. i, ch. 7, p. 94. (A., 1854.)

3372. TEMPERATURE OF THE DEEP SEA — *Depths Intensely Cold.* — The temperature of the water in the abyss is by no means constant for a constant depth, nor does it vary with the latitude. It is true that, as a rule, the water is colder at greater

depths than in shallower ones, and that the deeper the thermometer is lowered into the sea the lower the mercury sinks. This is consistent with physical laws. If there is any difference at all in the temperature of a column of water that has had time to settle, the thermometer will always reach its highest point at the top of the column and its lowest at the bottom, for the colder particles, being of greater specific gravity than the warmer ones, will sink, and the warmer ones will rise.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 28. (A., 1894.)

3373. TEMPERATURES DIFFER IN DEEP SEA—*Ridges Shut Off Polar Cold.*—If the ocean were a simple basin somewhat deeper at the equator than at the poles, the cold water at the poles would gradually sink down the slopes of the basin towards the latitude of the equator, and the bottom temperature of the water would be constant all the world over. A few hills here and there would not affect the general statement that for a constant depth the temperature of the lowest stratum of water would be constant. But in some places ridges occur stretching across the oceans from continent to continent, and these ridges shut off the cold water at the bottom of the sea on the polar side from reaching the bottom of the sea on the equator side. . . . These facts then show that, altho at the bottom of the deep sea the water is always very cold, the degree of coldness is by no means constant in the same latitude for the same depth.—HICKSON *Fauna of the Deep Sea*, ch. 2, p. 31. (A., 1894.)

3374. TENACITY OF LIFE OF BACTERIA—*Disease-germs Living in Soil Sixteen Years.*—Farm soils have, as is well known, been contaminated with anthrax in the late summer or autumn, and have retained the infectious virus till the following spring, and it has even then cropped up again in the hay of the next season. In 1881 Miquel took some samples of soil at a depth of ten inches, containing six and a half million bacteria per gram. After drying for two days at 30° C., the dust was placed in hermetically sealed tubes, which were put aside in a dark corner of the laboratory for sixteen years. Upon reexamination it is reported that more than three million germs per gram were still found, amongst them the specific bacillus of tetanus. Whether or not there is any fallacy in these actual figures, there is abundant evidence in support of the fact that bacteria, non-pathogenic and pathogenic, can and do retain their vitality, and sometimes even their virulence, for almost incredibly long periods of time.—NEWMAN *Bacteria*, ch. 5, p. 174. (G. P. P., 1899.)

3375. TENDERNESS OF ANTS TO THEIR YOUNG—*Feminine Care and Delicacy toward the Newly Born.*—After remaining some days in this [pupal] state they [ants] emerge as perfect insects. In many cases, however, they would perish in the attempt if they were not assisted; and it is very pretty to see the older ants helping them to extricate themselves, carefully unfolding their legs and smoothing out the wings, with truly feminine tenderness and delicacy. Our countryman, Gould, was the first to observe, and the fact has since been fully confirmed by Forel, that the pupæ are unable to emerge from the cocoons without the assistance of the workers.—AVEBURY *Ants, Bees, and Wasps*, ch. 1, p. 7. (A., 1900.)

3376. TERROR OF DARKNESS AND GLOOM HEREDITARY—*Caverns Inspire Dread.*—Black things, and especially dark places, holes, caverns, etc., arouse a peculiarly gruesome fear. This fear, as well as that of solitude, of being "lost," are explained after a fashion by ancestral experience. Says Schneider:

"It is a fact that men, especially in childhood, fear to go into a dark cavern or a gloomy wood. This feeling of fear arises, to be sure, partly from the fact that we easily suspect that dangerous beasts may lurk in these localities—a suspicion due to stories we have heard and read. But, on the other hand, it is quite sure that this fear at a certain perception is also directly inherited. Children who have been carefully guarded from all ghost-stories are nevertheless terrified and cry if led into a dark place, especially if sounds are made there. Even an adult can easily observe that an uncomfortable timidity steals over him in a lonely wood at night, altho he may have the fixed conviction that not the slightest danger is near.

"This feeling of fear occurs in many men even in their own house after dark, altho it is much stronger in a dark cavern or forest. The fact of such instinctive fear is easily explicable when we consider that our savage ancestors through innumerable generations were accustomed to meet with dangerous beasts in caverns, especially bears, and were for the most part attacked by such beasts during the night and in the woods, and that thus an inseparable association between the perceptions of darkness of caverns and woods, and fear took place and was inherited."—JAMES *Psychology*, vol. ii, ch. 24, p. 418. (H. H. & Co., 1899.)

3377. TERROR OF EARTHQUAKE UNCONQUERABLE—Dr. Tschudi, in his interesting work, "Travels in Peru," describes strikingly the effect of an earthquake upon the native and upon the stranger. "No familiarity with the phenomenon can blunt this feeling. The inhabitant of Lima, who from childhood has frequently witnessed these convulsions of Nature, is roused from his sleep by the shock, and rushes from his apartment with the cry of *Misericordia!* The foreigner from the north of Europe, who knows nothing of earthquakes but by description, waits with impatience to feel

the movement of the earth, and longs to hear with his own ear the subterranean sounds which he has hitherto considered fabulous. With levity he treats the apprehension of a coming convulsion, and laughs at the fears of the natives; but as soon as his wish is gratified he is terror-stricken, and is involuntarily prompted to seek safety in flight."—HUMBOLDT *Cosmos*, vol. i, p. 215. (H., 1897.)

3378. TERROR OF HAWK OVERPOWERS MULTITUDES OF BIRDS—The sudden appearance overhead of this hawk [the marsh-hawk] produces an effect wonderful to witness. I have frequently seen all the inhabitants of a marsh struck with panic, acting as if demented, and suddenly grown careless to all other dangers; and on such occasions I have looked up confident of seeing the sharp-winged death suspended above them in the sky. All birds that happen to be on the wing drop down as if shot into the reeds or water; ducks away from the margin stretch out their necks horizontally and drag their bodies, as if wounded, into closer cover; not one bird is found bold enough to rise up and wheel about the marauder—a usual proceeding in the case of other hawks; while, at every sudden stoop the falcon makes, threatening to dash down on his prey, a low cry of terror rises from the birds beneath; a sound expressive of an emotion so contagious that it quickly runs like a murmur all over the marsh, as if a gust of wind had swept moaning through the rushes. As long as the falcon hangs overhead, always at a height of about forty yards, threatening at intervals to dash down, this murmuring sound, made up of many hundreds of individual cries, is heard swelling and dying away, and occasionally, when he drops lower than usual, rising to a sharp scream of terror.—HUDSON *Naturalist in La Plata*, ch. 5, p. 97. (C. & H., 1895.)

3379. TERROR OF THE NATIONS PASSES HARMLESSLY BY—*Earth Wrapped for Hours in the Tail of a Comet.*—On June 30, 1861, the earth passed, for the second time in this century, through the tail of a great comet. Many of our readers must remember the unexpected disclosure, on the withdrawal of the sun below the horizon on that evening, of an object so remarkable as to challenge universal attention. A golden-yellow planetary disk, wrapt in dense nebulosity, shone out while the June twilight of these latitudes was still in its first strength. . . . Its tail stretched outward just along the line of intersection of its own with the terrestrial orbit to an extent of fifteen million miles, so that our globe, happening to pass at the time, found itself during some hours involved in the flimsy appendage. No perceptible effects were produced by the meeting; it was known to have occurred by theory alone. A peculiar glare in the sky, thought by some to have distinguished the evening of June 30, was, at best, inconspicuous. Nor were there any symptoms of unusual electrical excitement. —CLERKE *History of Astronomy*, pt. ii, ch. 10, p. 398. (Bl., 1893.)

3380. TERROR, SUPERSTITIOUS—*Great Meteoric Storm of 1833.*—The most notable modern one [shower of meteors] was on November 13, 1833, and this was visible over much of the North-American continent, forming a spectacle of terrifying grandeur. An eye-witness in South Carolina wrote:

"I was suddenly awakened by the most distressing cries that ever fell on my ears. Shrieks of horror and cries for mercy I could hear from most of the negroes of the three plantations, amounting in all to about six hundred or eight hundred. While earnestly listening for the cause I heard a faint voice near the door calling my name. I arose, and, taking my sword, stood at the door. At this moment I heard the same voice still beseeching me to rise, and saying, 'O my God, the world is on fire!' I then opened the door, and it is difficult to say which excited me the most—the awfulness of the scene or the distressed cries of the negroes. Upwards of one hundred lay prostrate on the ground—some speechless and some with the bitterest cries, but with their hands raised, imploring God to save the world and them. The scene was truly awful; for never did rain fall much thicker than the meteors fell toward the earth; east, west, north, and south, it was the same."—LANGLEY *New Astronomy*, ch. 6, p. 194. (H. M. & Co., 1896.)

3381. TEST OF SCIENTIFIC THEORY—*Two Elements of Value.*—The value which every scientific theory possesses is measured by the number and importance of the objects which can be explained by it, as well as by the simplicity and universality of the causes which are employed in it as grounds of explanation. On the one hand, the greater the number and the more important the meaning of the phenomena explained by the theory, and the simpler, on the other hand, and the more general the causes which the theory assigns as explanations, the greater is its scientific value, the more safely we are guided by it, and the more strongly are we bound to adopt it. —HAECKEL *History of Creation*, vol. i, ch. 2, p. 25. (K. P. & Co., 1899.)

3382. TESTS, FUTILE, OF SPONTANEOUS GENERATION—*Death-point of Bacteria Not Yet Found—Supposed New Life a Survival of the Old.*—I have had several cases of survival [of germs] after four and five hours' boiling, some survivals after six, and one after eight hours' boiling. Thus far has experiment actually reached; but there is no valid warrant for fixing upon even eight hours as the extreme limit of vital resistance. Probably more extended researches (tho mine have been very extensive) would reveal germs more obstinate still. I

is also certain that we might begin earlier, and find germs which are destroyed by a temperature far below that of boiling water. In the presence of such facts, to speak of a death-point of bacteria and their germs would be unmeaning.—TYNDALL *Floating Matter of the Air,* essay 5, p. 307. (A., 1895.)

3383. TEXTILES OF PRIMITIVE MAN—*Early Patterns the Despair of Modern Imitators.*—The cotton-gin and power-loom are among the wonders of our age. Yet in that [primitive] day human fingers wrought the textile from first to last. They gathered the bark or wool, colored them to suit the primitive taste, spun and wove them with simple apparatus, and left upon the fabric patterns that are the despair of all modern machine-makers—patterns that are a pleasure to the eye by their infinite variety, replaced in modern fabrics by a dreary monotony that awakens pain instead of pleasure. —MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891, Proceedings of the Congress,* p. 408).

3384. THEOLOGY, ACCEPTANCE OF, READY MADE—*Spiritual Parasitism.*—There are still large numbers whose only contact with religion is through theological forms. . . . If the greatest minds of the church's past, having exercised themselves profoundly upon the problems of religion, formulated as with one voice a system of doctrine, why should the humble inquirer not gratefully accept it? Why go over the ground again? Why with his dim light should he betake himself afresh to Bible study, and with so great a body of divinity already compiled presume himself to be still a seeker after truth? Does not theology give him Bible truth in reliable, convenient, and, moreover, in logical propositions? There it lies extended to the last detail in the tomes of the fathers, or abridged in a hundred modern compendiums, ready made to his hand, all cut and dry, guaranteed sound and wholesome, why not use it?

Just because it is all cut and dry. Just because it is ready made. Just because it lies there in reliable, convenient, and logical propositions. The moment you appropriate truth in such a shape you appropriate a form. You cannot cut and dry truth. You cannot accept truth ready made without it ceasing to nourish the soul as truth. You cannot live on theological forms without becoming a parasite and ceasing to be a man.—DRUMMOND *Natural Law in the Spiritual World,* essay 10, p. 323. (H. Al.)

3385. THEOLOGY, ANCIENT, OPPOSED TO SCIENCE—*Bruno Burned by Inquisition — Galileo's Recantation.*—If the neighboring stars are placed at tens and hundreds of billions of miles from us, it is at quadrillions, at quintillions of miles that most of the stars lie which are visible in the sky in telescopic fields. What suns! What splendors! Their light comes from such distances! And it is these distant suns which human pride would like to make revolve round our atom; and it was for our eyes that ancient theology declared these lights, invisible without a telescope, were created! It was because the philosophical astronomer, Giordano Bruno, asserted these distant suns to be centers of other systems that the Inquisition caused him to be burned alive at Rome before the terrified people; and it was because Galileo persisted in maintaining that our planet is subject to the sun, and that that body is itself but a star lost in infinitude, that this same Inquisition ordered him under pain of death to kneel before the Gospels (Church of Minerva at Rome, June 22, 1633) and abjure the truth which his conscience believed!—FLAMMARION *Popular Astronomy,* bk. vi, ch. 5, p. 601. (A.)

3386. THEOLOGY THE HIGHEST SCIENCE—*Would Naturally Be Last to Reach Perfection.*—Theology continues to be considered, as it has always been, a thing apart. It remained still a stupendous and splendid construction, but on lines altogether its own. Nor is theology to be blamed for this. Nature has been long in speaking; even yet its voice is low, sometimes inaudible. Science is the true defaulter, for theology had to wait patiently for its development. As the highest of the sciences, theology in the order of evolution should be the last to fall into rank. It is reserved for it to perfect the final harmony.—DRUMMOND *Natural Law in the Spiritual World,* int., p. 15. (H. Al.)

3387. THEORIES ABANDONED BY GREAT SCIENTIST—*Newton Undetermined as to Nature of Gravitation.*—At the time, . . . that Newton recognized all movements of the cosmical bodies to be the results of one and the same force, he did not, like Kant, regard gravitation as an essential property of bodies, but considered it either as the result of some higher and still unknown power, or of "the centrifugal force of æther, which fills the realms of space, and is rarer within bodies, but increases in density outward." The latter view is set forth in detail in a letter to Robert Boyle (dated February 28, 1678), which ends with the words, "I seek the cause of gravity in the æther." Eight years afterward, as we learn from a letter he wrote to Halley, Newton entirely relinquished this hypothesis of the rarer and denser ether. It is especially worthy of notice that in 1717, nine years before his death, he should have deemed it necessary expressly to state, in the short preface to the second edition of his "Optics," that he did not by any means consider gravity as an "essential property of bodies"; while Gilbert, as early as 1600, regarded magnetism as a force inherent in all matter. So undetermined was even Newton,

the profound and experienced thinker, regarding the "ultimate mechanical cause" of all motion.—HUMBOLDT *Cosmos*, vol. iii, int., p. 22. (H., 1897.)

3388. THEORIES, CONFLICTING, OF GEOLOGISTS—*How Alpine Valleys Were Formed—Fracture vs. Erosion.*—To the physical geologist the conformation of the Alps and of mountain regions generally constitutes one of the most interesting problems of the present day. To account for this conformation, two hypotheses have been advanced, which may be respectively named the hypothesis of fracture and the hypothesis of erosion. Those who adopt the former maintain that the forces by which the Alps were elevated produced fissures in the earth's crust, and that the valleys of the Alps are the tracks of these fissures. Those who hold the latter hypothesis maintain that the valleys have been cut out by the action of ice and water, the mountains themselves being the residual forms of this grand sculpture. To the erosive action here indicated must be added that due to the atmosphere (the severance and detachment of rocks by rain and frost), as affecting the forms of the more exposed and elevated peaks.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 219. (A., 1898.)

3389. THEORIES FRAMED IN THE IDEAL WORLD—*Their Verification in the World of Fact—The Final Test the Gift of Prophecy (2 Pet. i, 19).*—Tho the region of physical theory lies thus behind the world of senses, the verifications of theory occur in that world. Laying the theoretic conception at the root of matters, we determine by deduction what are the phenomena which must of necessity grow out of this root. If the phenomena thus deduced agree with those of the actual world, it is a presumption in favor of the theory. If, as new classes of phenomena arise, they also are found to harmonize with theoretic deduction, the presumption becomes still stronger. If, finally, the theory confers prophetic vision upon the investigator, enabling him to predict the occurrence of phenomena which have never yet been seen, and if those predictions be found on trial to be rigidly correct, the persuasion of the truth of the theory becomes overpowering. — TYNDALL *Lectures on Light*, lect. 2, p. 47. (A., 1898.)

3390. THEORIES OF CREATION—*False Alternatives of Spencer—Creator Not External, but Immanent.*—Spencer says: "The verbally intelligent suppositions respecting the origin of the universe are three: (1) It is self-existent; (2) it is self-created; (3) it is created by an external agency." On these it may be remarked that the second is scarcely even "verbally intelligent"; it seems to be a contradiction in terms. The third admits of an important modification, which was manifest to Spinoza, if not to Spencer—namely, that the Creator may—nay, must—be not merely "external," but within the universe as well. If there is a God, he must be in the universe as a pervading power, and in every part of it, and must not be shut out from his own work. This mistaken conception of God as building himself out of his own universe and acting on it by external force is both irrational and unscientific, being, for example, quite at variance with the analogy of force and life. Rightly understood, therefore, Spencer's alternatives resolve themselves into two—either the universe is self-existent, or it is the work of a self-existent Creator pervading all things with his power. —DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 29. (A. B. P. S.)

3391. THEORIES OF SLOW GROWTH—*Undulatory Theory of Light.*—Not in a moment are great theories elaborated: the facts which demand them are first called into prominence by observant minds; then, to the period of observation succeeds a period of pondering and of tentative explanation. By such efforts the human mind is gradually prepared for the final theoretic illumination. The colors of thin plates, for example, occupied the attention of the celebrated Robert Boyle. In his "Experimental History of Colors" he contends against the schools which affirmed that color was "a penetrative quality that reaches to the innermost parts of the object," adducing opposing facts. [It was not till a century later, however, that the undulatory theory of light was finally established by Thomas Young.]—TYNDALL *Lectures on Light*, lect. 2, p. 68. (A., 1898.)

3392. THEORIES OF THE HEAVENS—*Pictures Made to Illustrate—A True Map of the Skies—Preconceived Opinions Disregarded.*—It occurred to me very early in my inquiry into the great problem, and before I had fully investigated the long and noble series of researches by which Sir W. Herschel had attempted to master it, that this was a case where the mental vision must be assisted by the bodily vision. It is singular that hitherto, so far as I know (and I think little that has been done on the subject has escaped my reading), the idea of picturing the results obtained by telescopic scrutiny had been altogether overlooked. I do not here refer to pictures illustrating theories of the universe. Every student of astronomy knows that Sir W. Herschel was careful to give diagrams illustrating his successive conceptions of the structure of the universe. But such illustrations as these, tho necessary and useful, cannot throw any light on the structure of the universe, since they illustrate theories already formed, not facts on which theories are to be based. What seemed to me most desirable was that charts should be constructed on which the results of telescopic observation should be carefully mapped down without reference to any preconceived opinions, and solely with the in-

tention of interpreting as satisfactorily as possible whatever laws of stellar distribution may really exist. It appeared to me that mere lists of numbers could afford but unsatisfactory evidence on such points. —PROCTOR *Expanse of Heaven*, p. 263. (L. G. & Co., 1897.)

3393. THEORIES PERISH, FACTS REMAIN—*Planetary Motions Constant—Human Systems Progressive—Gravitation May Be Superseded.*—When . . . we come to study the history of science, the distinction between fact and theory obtrudes itself at once upon our attention. We see that, while the prominent facts of science have remained the same, its history has been marked by very frequent revolutions in its theories or systems. The courses of the planets have not changed since they were watched by the Chaldean astronomers, three thousand years ago; but how differently have their motions been explained—first by Hipparchus and Ptolemy, then by Copernicus and Kepler, and lastly by Newton and Laplace!—and, however great our faith in the law of universal gravitation, it is difficult to believe that even this grand generalization is the final result of astronomical science.—COOKE *The New Chemistry*, lect. 1, p. 1. (A., 1899.)

3394. THEORIES, TENTATIVE, OF ORIGIN OF CAVES—*Earthquakes Not the Cause—Water Alone Could Not Excavate—Truth the Outcome of Many Errors.*—It was at no very distant date pretty generally believed that caves were due to internal contortions of the crust of the earth, by which the rocks were rent asunder, leaving gaps and breaks such as we now see. But an examination of the interior of the caves soon showed that this was quite an impossible explanation, for it was found that both the floor and the roof were composed of solid rock, and that so far from there being any indication of folding and crumbling of the mass, which could account for the existence of a cavity, the rock was, in fact, unbroken both above and below, and in most cases the lie of the beds was perfectly continuous. Then, again, it was supposed that the caves had been worn by the mechanical action of running water alone, in places where a fault occurred in the rock—that is, where, from a local displacement of the beds, one portion of the series was elevated above or depressed below its normal level, thus leaving a vertical or diagonal crack, which might well be supposed to be a line of weakness. Probable as this view appears, it was, however, found that the caves did not, in fact, follow these lines, but were sometimes seen actually to be excavated across them, and yet another theory [that of erosion by carbonated water] was necessary to elucidate their origin.—DALLAS *Nature-Studies*, p. 39. (Hum., 1888.)

3395. THEORY ABANDONED—*Interior of the Sun Not a Cool, Dark Body.*—Spectrum analysis has further taught us more about the sun, by which he is brought nearer to us, as it were, than could formerly have seemed possible. You know that the sun is an enormous sphere, whose diameter is 112 times as great as that of the earth. We may consider what we see on its surface as a layer of incandescent vapor, which, to judge from the appearances of the sun-spots, has a depth of about 500 miles. This layer of vapor, which is continually radiating heat on the outside, and is certainly cooler than the inner masses of the sun, is, however, hotter than all our terrestrial flames—hotter even than the incandescent carbon-points of the electrical arc, which represent the highest temperature attainable by terrestrial means. . . . The older assumption that the sun is a dark, cool body, surrounded by a photosphere which only radiates heat and light externally, contains a physical impossibility.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 157. (L. G & Co., 1898.)

3396. THEORY AND FACT — *The Tragedy of Science.*—The great tragedy of science—the slaying of a beautiful hypothesis by an ugly fact—which is so constantly being enacted under the eyes of philosophers, was played, almost immediately, for the benefit of Buffon and Needham [regarding their theory of "organic molecules," *i. e.*, of universal and indestructible molecular life]. —HUXLEY *Lay Sermons*, serm. 15, p. 356. (A., 1895.)

3397. THEORY AND PRACTICE—*Skill in Action Not Coextensive with Knowledge of Principles.*—Expertness in the performance of an art does not depend on a knowledge of its principles, and can be readily acquired without reference to them. The most expert accountants are frequently and perhaps generally those who have no knowledge of the philosophy of figures. On the other hand, a profound acquaintance with the principles of an art may exist without the ability to apply it in practise. I have known of mathematicians who were unable to perform with accuracy and despatch the processes which constitute the application of the simple rules of multiplication and addition. The same is the case with the art of composition. A most learned rhetorician is not necessarily a fluent and pleasing writer. The acquisition, therefore, of these arts should be the principal and prominent object of the primary or common school, and nothing ought to be suffered to usurp their place. . . . I may venture to say that the general substitution of instruction in the mere rationale of the rules of arithmetic without a proper drilling in the practise would produce more bankruptcies than all the changes of tariffs or fluctuations of trade.—HENRY *Thoughts on Education (Scientific Writings*, vol. i, p. 336). (Sm. Inst., 1886.)

3398. THEORY, ATOMIC, FORESHADOWED — Surely it cannot be said that Boyle [1626-1692] had not perceived that it was the province of science to concern herself not with matter, but with the changes in matter. "I am apt to think," he avers, "that men will never be able to explain the phenomena of Nature while they endeavor to deduce them only from the presence and proportions of such and such material ingredients, and consider such ingredients or elements as bodies in a state of rest; whereas, indeed, the greatest part of the affections of matter, and consequently of the phenomena of Nature, seems to depend upon the motion and contrivance of the small parts of bodies."—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 13, p. 416. (J. W., 1898.)

3399. THEORY, ATTEMPT TO SHAPE SCIENCE TO FIT—*A "Convenient Generalization" in Chemistry.*—We are afraid it must also be said—tho shown only by slight indications in his fundamental work, and coming out in full evidence only in his later writings—that M. Comte, at bottom, was not so solicitous about completeness of proof as becomes a positive philosopher, and that the unimpeachable objectivity, as he would have called it, of a conception—its exact correspondence to the realities of outward fact—was not, with him, an indispensable condition of adopting it, if it was subjectively useful, by affording facilities to the mind for grouping phenomena. This appears very curiously in his chapters on the philosophy of chemistry. He recommends, as a judicious use of "the degree of liberty left to our intelligence by the end and purpose of positive science," that we should accept as a convenient generalization the doctrine that all chemical composition is between two elements only.—MILL *Positive Philosophy of Auguste Comte*, p. 55. (H. H. & Co., 1887.)

3400. THEORY CONFIRMED BY FACT—*Neptune Found Where Gravitation Demanded.*—By it [the discovery of Neptune] the last lingering doubts as to the absolute exactness of the Newtonian law were dissipated. Recondite analytical methods received a confirmation brilliant and intelligible even to the minds of the vulgar, and emerged from the patient solitude of the study to enjoy an hour of clamorous triumph. Forever invisible to the unaided eye of man, a sister-globe to our earth was shown to circulate, in perpetual frozen exile, at thirty times its distance from the sun. Nay, the possibility was made apparent that the limits of our system were not even thus reached, but that yet profounder abysses of space might shelter obedient tho little favored members of the solar family, by future astronomers to be recognized through the sympathetic thrillings of Neptune, even as Neptune himself was recognized through the telltale deviations of Uranus.—CLERKE *History of Astronomy*, pt. i, ch. 4, p. 102. (Bl., 1893.)

3401. THEORY, FALSE, MAKES MEN BLIND TO FACTS—*Sea, Not Land, is Permanent.*—The interminable controversies to which the phenomena of the Bay of Baiæ [the rise and subsidence of the level of the Temple of Serapis] gave rise have sprung from an extreme reluctance to admit that the land, rather than the sea, is subject alternately to rise and fall. Had it been assumed that the level of the ocean was invariable, on the ground that no fluctuations have as yet been clearly established, and that, on the other hand, the continents are inconstant in their level, as has been demonstrated by the most unequivocal proofs again and again, from the time of Strabo to our own times, the appearances of the temple at Puzzuoli could never have been regarded as enigmatical. Even if contemporary accounts had not distinctly attested the upraising of the coast, this explanation should have been proposed in the first instance as the most natural, instead of being now adopted unwillingly when all others have failed.

To the strong prejudices still existing in regard to the mobility of the land, we may attribute the rarity of such discoveries as have been recently brought to light in the Bay of Baiæ. A false theory, it is well known, may render us blind to facts which are opposed to our prepossessions, or may conceal from us their true import when we behold them. But it is time that the geologist should, in some degree, overcome those first and natural impressions which induced the poets of old to select the rock as the emblem of firmness—the sea as the image of inconstancy. Our modern poet, in a more philosophical spirit, saw in the sea "the image of eternity," and has finely contrasted the fleeting existence of the successive empires which have flourished and fallen on the borders of the ocean with its own unchanged stability.

> ——— Their decay
> Has dried up realms to deserts:—not so thou,
> Unchangeable save to thy wild wave's play:
> Time writes no wrinkle on thine azure brow;
> Such as creation's dawn beheld, thou rollest now.
> —BYRON *Childe Harold*, canto iv.

—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 518. (A., 1854.)

3402. THEORY MUST POINT THE WAY FOR EXPERIMENT — *Experiment Must Be the Test of Theory.*—The conviction is constantly gaining ground, that in the present more advanced state of science those only can experimentalize profitably who have a clear-sighted knowledge of theory, and know how to propound and pursue the right questions: and, on the other hand, only those can theorize with advantage who have great practise in experiments. The discovery of spectrum analysis is the most brilliant example within our recollec-

tion of such an interpenetration of theoretical knowledge and experimental skill.—HELMHOLTZ *Popular Lectures*, lect. 1, p. 19. (L. G. & Co., 1898.)

3403. THEORY OF CREATION—*Sketch of the Nebular Hypothesis.*—In their view [*i. e.*, the view of Kant and Laplace, known as "the nebular hypothesis"] our system was originally a chaotic ball of nebulous matter, of which originally, when it extended to the path of the most distant planet, many billions of cubic miles could contain scarcely a gram of mass. This ball, when it had become detached from the nebulous balls of the adjacent fixed stars, possessed a slow movement of rotation. It became condensed under the influence of the reciprocal attraction of its parts; and, in the degree in which it condensed, the rotatory motion increased, and formed it into a flat disk. From time to time masses at the circumference of this disk became detached under the influence of the increasing centrifugal force; that which became detached formed again into a rotating nebulous mass, which either simply condensed and formed a planet, or during this condensation again repelled masses from the periphery, which became satellites, or in one case, that of Saturn, remained as a coherent ring. In another case the mass which separated from the outside of the chief ball divided into many parts, detached from each other, and furnished the swarms of small planets between Mars and Jupiter.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 173. (L. G. & Co., 1898.)

3404. THEORY OF "CRYSTAL SPHERES"—*The Conception of the Middle Ages—Destruction of Theory by Kepler.*—The idea of a crystalline vault of heaven was handed down to the Middle Ages by the fathers of the church, who believed the firmament to consist of from seven to ten glassy strata, incasing one another like the different coatings of an onion. This supposition still keeps its ground in some of the monasteries of Southern Europe, where I was greatly surprised to hear a venerable prelate express an opinion in reference to the fall of aerolites at Aigle, which at that time formed a subject of considerable interest, that the bodies we called meteoric stones with vitrified crusts were not portions of the fallen stone itself, but simply fragments of the crystal vault shattered by it in its fall. Kepler, from his considerations of comets which intersect the orbits of all the planets, boasted, nearly two hundred and fifty years ago, that he had destroyed the seventy-seven concentric spheres of the celebrated Girolamo Fracastoro, as well as all the more ancient retrograde epicycles.—HUMBOLDT *Cosmos*, vol. iii, p. 125. (H., 1897.)

3405. ——— ——— *The System of Pythagoras—"Music of the Spheres."*—He [Pythagoras] is said to have taught that the heavenly bodies were set in a number of crystalline spheres, in the common center of which the earth was placed. In the outer of these spheres were set the thousands of fixed stars which stud the firmament, while each of the seven planets had its own sphere. The transparency of each crystal sphere was perfect, so that the bodies set in each of the outer spheres were visible through all the inner ones. These spheres all rolled round on each other in a daily revolution, thus causing the rising and setting of the heavenly bodies. This rolling of the spheres on each other made a celestial music, the "music of the spheres," which filled the firmament, but was of too elevated a character to be heard by the ears of mortals.—NEWCOMB *Popular Astronomy*, pt. i, int., p. 3. (H., 1899.)

3406. THEORY OF DEW—*An Effect of Chilling by Radiation.*—A series of experiments, conceived and executed with admirable clearness and skill, enabled Dr. Wells to propound a theory of dew, which has stood the test of all subsequent criticism, and is now universally accepted. It is an effect of chilling by radiation. "The upper parts of the grass radiate their heat into regions of empty space, which, consequently, send no heat back in return; its lower parts, from the smallness of their conducting power, transmit little of the earth's heat to the upper parts, which, at the same time, receiving only a small quantity from the atmosphere, and none from any other lateral body, must remain colder than the air, and condense into dew its watery vapor, if this be sufficiently abundant in respect to the decreased temperature of the grass." Why the vapor itself, being a powerful radiant, is not so quickly chilled as the grass, has been already explained on the ground that the vapor has not only its own heat to discharge, but also that of the large mass of air by which it is surrounded. Dew, then, is the result of the condensation of atmospheric vapor, on substances which have been sufficiently cooled by radiation; and as bodies differ widely in their radiative powers, we may expect corresponding differences in the deposition of dew. This Wells proved to be the case. He often saw dew copiously deposited on grass and painted wood, when none could be observed on gravel walks adjacent.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 498. (A., 1900.)

3407. THEORY OF "FACULTIES" A BONDAGE—*Feeling, Desire, Impulse, and Will Combine in Free Choice.*—It is in the doctrine of feeling and will more than anywhere else that psychology still wears the fetters of the old faculty theory. . . . Thus first of all feeling was considered apart from its connection with will, and then desire was treated as a separate process, sometimes found in connection with feeling. Further, impulse was opposed to desire proper as an obscure desire, in which the subject is not

conscious of the desired object; or, perhaps, as a lower desire, referring exclusively to the needs of sense. (That is why many psychologists hold that impulses only exist among animals.) And finally these processes are still further supplemented by the postulation of will as an entirely new and independent faculty, whose function it is to choose between the various objects of desire, or in certain circumstances to act in accordance with purely intellectual motives and in opposition to impulses and desires. According to this theory, that is, will consists in the capacity for free choice. Choice in this sense presupposes the possibility of decision between various objects of desire, and even of decision against the desired object on the ground of purely rational considerations.—WUNDT *Psychology*, lect. 15, p. 224. (Son. & Co., 1896.)

3408. THEORY OF MORALITY DOES NOT SAVE—*Lower Impulses Given the Right of Way—The Limp Character.*—Men do not differ so much in their mere feelings and conceptions. Their notions of possibility and their ideals are not as far apart as might be argued from their differing fates. No class of them have better sentiments or feel more constantly the difference between the higher and the lower path in life than the hopeless failures, the sentimentalists, the drunkards, the schemers, the "dead-beats," whose life is one long contradiction between knowledge and action, and who, with full command of theory, never get to holding their limp characters erect. No one eats of the fruit of the tree of knowledge as they do; as far as moral insight goes, in comparison with them, the orderly and prosperous philistines whom they scandalize are sucking babes. And yet their moral knowledge, always there grumbling and rumbling in the background—discerning, commenting, protesting, longing, half resolving—never wholly resolves, never gets its voice out of the minor into the major key, or its speech out of the subjunctive into the imperative mood, never breaks the spell, never takes the helm into its hands. In such characters as Rousseau and Restif it would seem as if the lower motives had all the impulsive efficacy in their hands. Like trains with the right of way, they retain exclusive possession of the track. The more ideal motives exist alongside of them in profusion, but they never get switched on, and the man's conduct is no more influenced by them than an express train is influenced by a wayfarer standing by the roadside and calling to be taken aboard. They are an inert accompaniment to the end of time; and the consciousness of inward hollowness, that accrues from habitually seeing the better only to do the worse, is one of the saddest feelings one can bear with him through this vale of tears. —JAMES *Psychology*, vol. ii, ch. 26, p. 547. (H. H. & Co., 1899.)

3409. THEORY, PRECONCEIVED, RETARDS SCIENCE—*All Fossils Assigned to the Deluge—Medieval Geology.*—The theologians who now [1670] entered the field in Italy, Germany, France, and England, were innumerable; and henceforward they who refused to subscribe to the position, that all marine organic remains were proofs of the Mosaic deluge, were exposed to the imputation of disbelieving the whole of the sacred writings. Scarcely any step had been made in approximating to sound theories since the time of Fracastoro, more than a hundred years having been lost in writing down the dogma that organized fossils were mere sports of Nature. An additional period of a century and a half was now destined to be consumed in exploding the hypothesis that organized fossils had all been buried in the solid strata by Noah's flood. Never did a theoretical fallacy, in any branch of science, interfere more seriously with accurate observation and the systematic classification of facts. In recent times we may attribute our rapid progress chiefly to the careful determination of the order of succession in mineral masses, by means of their different organic contents and their regular superposition. But the old diluvialists were induced by their system to confound all the groups of strata together instead of discriminating—to refer all appearances to one cause and to one brief period, not to a variety of causes acting throughout a long succession of epochs. They saw the phenomena only as they desired to see them, sometimes misrepresenting facts, and at other times deducing false conclusions from correct data. Under the influence of such prejudices three centuries were of as little avail as a few years in our own times, when we are no longer required to propel the vessel against the force of an adverse current. —LYELL *Principles of Geology*, bk. i, ch. 3, p. 25. (A., 1854.)

3410. THEORY PROVED BY EXPERIMENT—*Science Demands the Test of Fact—Structure of Orchid Compels Bee to Gather Pollen.*—I . . . caught and placed within the labellum [of *Cypripedium pubescens*] a very small bee which seemed of about the right size. . . . The bee vainly endeavored to crawl out again the same way by which it had entered, but always fell backwards, owing to the margins being inflected. The labellum thus acts like one of those conical traps, with the edges turned inwards, which are sold to catch beetles and cockroaches in the London kitchens. It could not creep out through the slit between the folded edges of the basal part of the labellum, as the elongated, triangular, rudimentary stamen here closes the passage. Ultimately it forced its way out through one of the small orifices close to one of the anthers, and was found when caught to be smeared with the glutinous pollen. I then put the same bee back into the labellum;

and again it crawled out through one of the small orifices, always covered with pollen. I repeated the operation five times, always with the same result. I afterwards cut away the labellum, so as to examine the stigma, and found its whole surface covered with pollen. It should be noticed that an insect in making its escape must first brush past the stigma and afterwards one of the anthers, so that it cannot leave pollen on the stigma, until, being already smeared with pollen from one flower, it enters another; and thus there will be a good chance of cross-fertilization between two distinct plants.—DARWIN *Fertilization of Orchids*, ch. 8, p. 231. (A., 1898.)

3411. THEORY STRONGER THAN EVIDENCE — *Testimony Discredited — Facts Held to be Contrary to the Uniformity of Nature — The Falling of Meteorites Pronounced Impossible.*—When induced to give the matter consideration, they [early scientists] observed that all the conditions for scientific observation were violated by these bodies [meteorites], since the wonder always happened at some far-off place or at some past time, and (suspicious circumstance!) the stones only fell in the presence of ignorant and unscientific witnesses, and never when scientific men were at hand to examine the facts. That there were many worthy if ignorant men who asserted that they had seen such stones fall, seen them with their very eyes, and held them in their own hands, was accounted for by the general love of the marvelous and by the ignorance of the common mind, unlearned in the conditions of scientific observation, and unguided by the great principle of the uniformity of the laws of Nature.—LANGLEY *New Astronomy*, ch. 6, p. 175. (H. M. & Co., 1896.)

3412. THEORY, TRUE, OF THE UNIVERSE—*Its Beneficent Effect—Advance of Science Uninterrupted from Time of Copernicus.*—The scientific revolution originated by Nicolaus Copernicus has had the rare fortune (setting aside the temporary retrograde movement imparted by the hypothesis of Tycho Brahe) of advancing without interruption to its object—the discovery of the true structure of the universe. The rich abundance of accurate observations furnished by Tycho Brahe himself, the zealous opponent of the Copernican system, laid the foundation for the discovery of those eternal laws of the planetary movements which prepared imperishable renown for the name of Kepler, and which, interpreted by Newton, and proved to be theoretically and necessarily true, have been transferred into the bright and glorious domain of thought as the intellectual recognition of Nature. It has been ingeniously said, altho, perhaps, with too feeble an estimate of the free and independent spirit which created the theory of gravitation, that "Kepler wrote a code of laws, and Newton the spirit of those laws."—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 313. (H., 1897.)

3413. THEORY VAIN BY DEATH-BED—*Practise of Medicine the Constant Test of Science.*—I consider the study of medicine to have been that training which preached more impressively and more convincingly than any other could have done the everlasting principles of all scientific work; principles which are so simple and yet are ever forgotten again; so clear and yet always hidden by a deceptive veil.

Perhaps only he can appreciate the immense importance and the fearful practical scope of the problems of medical theory who has watched the fading eye of approaching death, and witnessed the distracted grief of affection, and who has asked himself the solemn questions, Has all been done which could be done to ward off the dread event? Have all the resources and all the means which science has accumulated become exhausted? — HELMHOLTZ *Popular Lectures*, lect. 5, p. 203. (L. G. & Co., 1898.)

3414. THEORY VALUABLE FOR RETENTION OF FACTS—The great memory for facts which a Darwin or a Spencer reveal in their books is not incompatible with the possession on their part of a mind with only a middling degree of physiological retentiveness. Let a man early in life set himself the task of verifying such a theory as that of evolution, and facts will soon cluster and cling to him like grapes to their stem. Their relations to the theory will hold them fast; and the more of these the mind is able to discern the greater the erudition will become. Meanwhile the theorist may have little, if any, desultory memory. Unutilizable facts may be unnoted by him, and forgotten as soon as heard. An ignorance almost as encyclopedic as his erudition may coexist with the latter, and hide, as it were, within the interstices of its web. Those of you who have had much to do with scholars and savants will readily think of examples of the class of mind I mean.—JAMES *Talks to Teachers*, ch. 12, p. 125. (H. H. & Co., 1900.)

3415. THEORY VS. EXPERIMENT IN MEDICINE—*Love of a Sweeping Clever Stroke—A Credulous Multitude Never Wanting.*—Do not think, gentlemen, that the struggle [between theory and experiment in medicine] is at an end. As long as there are people of such astounding conceit as to imagine that they can effect, by a few clever strokes, that which man can otherwise only hope to achieve by toilsome labor, hypotheses will be started which, propounded as dogmas, at once promise to solve all riddles. And as long as there are people who believe implicitly in that which they wish to be true, so long will the hypotheses of the former find credence. Both classes

will certainly not die out, and to the latter the majority will always belong.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 224. (L. G. & Co., 1898.)

3416. THICKNESS OF EARTH'S CRUST—*Theories Corrected by Advancing Science.*—The earth is known gradually to augment in temperature as we pierce it deeper, and the depth has been calculated at which all known terrestrial bodies would be in a state of fusion. Owing, however, to the enormous pressure of the superincumbent layers, the deeper strata, according to Mr. Hopkins, would require a far higher temperature to fuse them than would suffice to fuse the strata near the earth's surface. Hence he inferred that the solid crust must have a considerably greater thickness than that given by a calculation which assumes the fusing points of the superficial and the deeper strata to be the same. Mr. Hopkins, therefore, rejected the estimate of geologists that the earth could be a molten nucleus covered by a crust only 100 miles in thickness, concluding that the depth of the crust must be at least 800 miles. Sir William Thomson considers it "extremely improbable that any crust thinner than 2,000 or 2,500 miles could maintain its figure with sufficient rigidity against the tide-generating forces of sun and moon, to allow the phenomena of the ocean tides and of precession and nutation to be as they now are."—TYNDALL *Heat a Mode of Motion*, lect. 6, p. 148. (A., 1900.)

3417. "THING IN ITSELF"—*The Unconditioned Unthinkable, and also Incredible.*—In metaphysics the assertion that we can never attain to any knowledge of things "in themselves" does not mean simply that we know things only in a few relations out of many. It does not mean even that there may be and probably are a great many relations which we have not faculties enabling us to conceive. All this is quite true, and a most important truth. But the metaphysical distinction is quite different. It affirms that if we knew things in every one of the relations that affect them, we should still be no nearer than before to a knowledge of "things in themselves." . . .

Now, as the very idea of knowledge consists in the perception of relations, this affirmation is, in the purest sense of the word, nonsense—that is to say, it is a series of words which have either no meaning at all or a meaning which is self-contradictory. It belongs to the class of propositions which throw just discredit on metaphysics—mere verbal propositions, pretending to deal with conceptions which are no conceptions at all, but empty sounds. The "unconditioned," we are told, "is unthinkable"; but words which are unthinkable had better be also unspeakable, or at least unspoken. It is altogether untrue that we are compelled to believe in the existence of anything which is "unconditioned"—in matter with no qualities—in minds with no character—in a God with no attributes. Even the metaphysicians who dwell on this distinction between the relative and the unconditioned admit that it is one to which no idea can be attached. Yet, in spite of this admission, they proceed to found many inferences upon it, as if it had an intelligible meaning.—ARGYLL *Unity of Nature*, ch. 4, p. 90. (Burt.)

3418. THIRST OF ALPINE CLIMBER—*Milk a Perfect Refreshment.*—During the previous night I had been very unwell, and as I climbed the slope I suffered from intense thirst. Water seemed powerless to quench the desire for drink. We reached a chalet, and at our request a smart young Senner caught up a pail and soon returned with it full of delicious milk. The effect of the milk was astonishing. It seemed to lubricate every atom of my body, and to exhilarate with its fragrance my brain.—TYNDALL *Hours of Exercise in the Alps*, ch. 9, p. 92. (A., 1898.)

3419. ——— ——— *Snow and Ice Increase Distress.*—We had plodded on for hours soddened by the solar heat and parched with thirst. There was

Water, water everywhere,
But not a drop to drink;

for, when placed in the mouth, the liquefaction of the ice was so slow, and the loss of heat from the surrounding tissues so painful, that sucking it was worse than total abstinence. In the midst of this solid water you might die of thirst.—TYNDALL *Hours of Exercise in the Alps*, ch. 15, p. 170. (A., 1898.)

3420. THOUGHT AND FEELING HAVE NO EXTENSION—*Intense Pleasure or Pain Annuls Space and Time.*—When I am studying a brain and nerve-communications, I am engrossed with properties exclusively belonging to the object or material world. I am unable at that moment (except by very rapid transitions or alternations) to conceive a truly mental fact, my truly mental consciousness. Our mental experience, our feelings and thoughts, have no extension, no place, no form or outline, no mechanical division of parts; and we are incapable of attending to anything mental until we shut off the view of all that. Walking in the country in spring, our mind is occupied with the foliage, the bloom, and the grassy meads—all purely objective things: we are suddenly and strongly arrested by the odor of the May blossom; we give way for a moment to the sensation of sweetness; for that moment the objective regards cease; we think of nothing extended; we are in a state where extension has no footing; there is, to us, place no longer. Such states are of short duration, mere fits, glimpses; they are constantly shifted and alternated with object states, but while they last and have their full power we are in a different world; the material world is blot-

ted out, eclipsed, for the instant unthinkable. These subject moments are studied to advantage in bursts of intense pleasure or intense pain, in fits of engrossed reflection, especially reflection upon mental facts; but they are seldom sustained in purity beyond a very short interval; we are constantly returning to the object side of things —to the world whose basis is extension and place.—BAIN *Mind and Body*, ch. 6, p. 34. (Hum., 1880.)

3421. THOUGHT AND MOTION NOT COMMENSURABLE — *Chasm between Consciousness and Mechanics.*—Every one admits the entire incommensurability of feeling as such with material motion as such. "A motion became a feeling!"—no phrase that our lips can frame is so devoid of apprehensible meaning. Accordingly, even the vaguest of evolutionary enthusiasts, when deliberately comparing material with mental facts, have been as forward as any one else to emphasize the "chasm" between the inner and the outer worlds.

"Can the oscillations of a molecule," says Mr. Spencer ["Psychology," § 62], "be represented side by side with a nervous shock [he means a mental shock], and the two be recognized as one? No effort enables us to assimilate them. That a unit of feeling has nothing in common with a unit of motion becomes more than ever manifest when we bring the two into juxtaposition."

And again ["Psychology," § 272]:

"Suppose it to have become quite clear that a shock in consciousness and a molecular motion are the subjective and objective faces of the same thing: we continue utterly incapable of uniting the two, so as to conceive that reality of which they are the opposite faces."

In other words, incapable of perceiving in them any common character. So Tyndall, in that lucky paragraph ["Fragments of Science," p. 420], which has been quoted so often that every one knows it by heart:

"The passage from the physics of the brain to the corresponding facts of consciousness is unthinkable. Granted that a definite thought and a definite molecular action in the brain occur simultaneously, we do not possess the intellectual organ, nor apparently any rudiment of the organ, which would enable us to pass, by a process of reasoning, from one to the other."

—JAMES *Psychology*, vol. i, ch. 6, p. 146. (H. H. & Co., 1899.)

3422. THOUGHT, ENLARGEMENT OF, BY VOLUNTARY STUDY—It is . . . by the use of the power which every man possesses of enlarging as well as improving his fabric of thought, by applying himself to the acquirement of new knowledge, that he gains a vastly increased capacity for the reception of a nobler and grander order of beliefs, such as he would have previously thought it impossible that he could ever come to possess.—CARPENTER *Nature and Man*, lect. 7, p. 234. (A., 1889.)

3423. THOUGHT, HUMAN, GROWS AROUND A FEW GREAT THINKERS—The thoughts of men seem rather to be comparable to the leaves, flowers, and fruit upon the innumerable branches of a few great stems, fed by commingled and hidden roots. These stems bear the names of the half a dozen men endowed with intellects of heroic force and clearness, to whom we are led, at whatever point of the world of thought the attempt to trace its history commences; just as certainly as the following up the small twigs of a tree to the branchlets which bear them, and tracing the branchlets to their supporting branches, brings us, sooner or later, to the bole.—HUXLEY *Lay Sermons*, serm. 14, p. 320. (G. P. P., 1899.)

3424. THOUGHT, ITS POWER IN MAN—The superiority of man over animals, of the scholar over the barbarian, depends upon thinking; sensation, feeling, perception, on the contrary, he shares with his lower fellow creatures, and in acuteness of the senses many of these are even superior to him. That man strives to develop his thinking faculty to the utmost is a problem on the solution of which the feeling of his own dignity as well as of his own practical power depends.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 206. (L. G. & Co., 1898.)

3425. THOUGHT, NEW, HOW MADE—We must not forget that everything new that can possibly be thought is nothing more than either a combination of particulars which had previously been separate, or a separation of particulars which had been combined. As thinking cannot be accomplished without feeling and perceptions, so it is with willing.—SCHWARZ *Psychologie des Willens (a Lecture)*. (Translated for *Scientific Side-Lights.)*

3426. THOUGHT, RAPIDITY OF, IN GREAT MINDS—When two minds of a high order, interested in kindred subjects, come together, their conversation is chiefly remarkable for the summariness of its allusions and the rapidity of its transitions. Before one of them is half through a sentence the other knows his meaning and replies. Such genial play with such massive materials, such an easy flashing of light over far perspectives, such careless indifference to the dust and apparatus that ordinarily surround the subject and seem to pertain to its essence, make these conversations seem true feasts for gods to a listener who is educated enough to follow them at all.—JAMES *Psychology*, vol. ii, ch. 22, p. 370. (H. H. & Co., 1899.)

3427. THOUGHTLESSNESS UNWARNED BY OTHERS' FATE—*Bees Perishing in Sweets.*—The following scene [says Sir John Lubbock], one which most of us have witnessed, is incompatible surely with much intelligence. The sad fate of their unfortunate companions does not in the least deter others who approach the tempting lure from madly alighting on the bodies of the dying and dead, to share the same miserable end. No one can understand the extent of their infatuation until he has seen a confectioner's shop assailed by myriads of hungry bees. I have seen thousands strained out from the sirup in which they

had perished; thousands more alighting even upon the boiling sweets, the floor covered and windows darkened with bees, some crawling, others flying, and others still so completely besmeared as to be able neither to crawl nor fly, not one in ten able to carry home its ill-gotten spoils, and yet the air filled with new hosts of thoughtless comers. —ROMANES *Animal Intelligence*, ch. 4, p. 184. (A., 1899.)

3428. THUNDER-STORM THE RELEASE OF STORED ENERGY—All of the phenomena of a thunder-storm, hail-storm, or tornado, with their terrific manifestations in the form of thunder, lightning, wind, and rain, are simply the result of a sudden releasing of the stored energy in the myriads of moisture spherules that were placed there by the power of the sun when they were silently and invisibly wrested from the surface of the water, or from condensed moisture globules floating in the air.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 2, p. 20. (F. H. & H., 1900.)

3429. TIME, ANCIENT METHODS OF MEASURING—*Difficulties Overcome by Ancient Astronomers.*—During many centuries time was only measured by sun-dials and water-clocks, or clepsydras. Water, running out regularly from a reservoir, is received in a vase which shows every hour. A float placed upon the liquid carries a little figure of a boy, which rises regularly and points to the hours. The ancient astronomers of China, Asia, Chaldea, and Greece measured in this way the hours of the night, the transits of stars across the meridian, and the duration of eclipses.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 2, p. 19. (A.)

3430. TIME, ELEMENT OF, IN BACTERIAL ANALYSIS—*Rapid Multiplication of Bacteria May Defeat Experiment.*—When the sample has been duly collected, sealed, and a label affixed bearing the date, time, and conditions of collection and full address, it should be transmitted with the least possible delay to the laboratory. Frequently it is desirable to pack the bottles in a small ice case for transit. On receipt of such a sample of water the examination must be immediately preceeded with, in order to avoid, as far as possible, the fallacies arising from the rapid multiplication of germs. Even in almost pure water, at the ordinary temperature of a room, Frankland found organisms multiplied as follows:

HOURS.	NO. OF GERMS PER C. C.
0	1,073
6	6,028
24	7,262
48	48,100

Another series of observations revealed the same sort of rapid increase of bacteria. On the date of collection the micro-organisms per c. c. in a deep-well water (in April) were seven. After one day's standing at room temperature the number had reached twenty-one per c. c. After three days under the same conditions it was 495,000 per c. c. At blood-heat the increase would, of course, be much greater, as a higher temperature is more favorable to multiplication.—NEWMAN *Bacteria*, ch. 2, p. 38. (G. P. P., 1899.)

3431. TIME, EVOLUTION GIVES NEW PERSPECTIVE OF—*Reveals the Unity of Nature.*—Evolution has done for time what astronomy has done for space. As sublime to the reason as the science of the stars, as overpowering to the imagination, it has thrown the universe into a fresh perspective, and given the human mind a new dimension. Evolution involves not so much a change of opinion as a change in man's whole view of the world and of life. It is not the statement of a mathematical proposition which men are called upon to declare true or false. It is a method of looking upon Nature. Science for centuries devoted itself to the cataloguing of facts and the discovery of laws. Each worker toiled in his own little place—the geologist in his quarry, the botanist in his garden, the biologist in his laboratory, the astronomer in his observatory, the historian in his library, the archeologist in his museum. Suddenly these workers looked up; they spoke to one another; they had each discovered a law; they whispered its name. It was "evolution." Henceforth their work was one, science was one, the world was one, and mind, which discovered the oneness, was one.—DRUMMOND *Ascent of Man*, int., p. 8. (J. P., 1900.)

3432. TIME, GEOLOGIC—*A Thousand Feet of Chalk Long in Depositing.*—The chalk [of the English cliffs] is in places more than a thousand feet thick. I think you will agree with me that it must have taken some time for the skeletons of animalcules of a hundredth of an inch in diameter to heap up such a mass as that. I have said that throughout the thickness of the chalk the remains of other animals are scattered. These remains are often in the most exquisite state of preservation. The valves of the shellfishes are commonly adherent; the long spines of some of the sea-urchins, which would be detached by the smallest jar, often remain in their places. In a word, it is certain that these animals have lived and died when the place which they now occupy was the surface of as much of the chalk as had then been deposited; and that each has been covered up by the layer of globigerina-mud, upon which the creatures embedded a little higher up have, in like manner, lived and died. But some of these remains prove the existence of reptiles of vast size in the chalk sea. These lived their time, and had their ancestors and descendants, which assuredly implies time, reptiles being of slow growth. . . . Thus, not only is it certain that the chalk is the

mud of an ancient sea-bottom, but it is no less certain that the chalk sea existed during an extremely long period, tho we may not be prepared to give a precise estimate of the length of that period in years.—HUXLEY *Lay Sermons*, serm. 9, p. 189. (G. P. P., 1899.)

3433. TIME, IMMEASURABLE LAPSE OF—*Ages Required to Build Chalk Cliffs.*—The chalk . . . now seen stretching for thousands of miles over different parts of Europe has become visible to us by the effect, not of one, but of many distinct series of subterranean movements. Time has been required, and a succession of geological periods, to raise it above the waves in so many regions.—LYELL *Principles of Geology*, bk. i, ch. 10, p. 159. (A., 1854.)

3434. TIME, INCREASING APPRECIATION OF—*Our Indebtedness to Ages of Thought and Observation.*—When we picture to ourselves the virtuosity with which every schoolchild is capable in our day of measuring off and dividing up his time, and how among our ordinary citizens the more many-sided their life becomes in all directions, the more it is based upon an ever-increasingly exact appropriation of time, and that our modern great means of transportation, the railroads and telegraphs, scarcely reckon otherwise than according to minutes, indicating thereby the exactitude of their division of time, then it becomes difficult to transport our thoughts back to that period when neither the fortunate nor the unfortunate had his hour. And yet we still remember yonder blessed childhood in which we, too, without regard for time, measured off our entire career according to nothing but days and nights, and the great pleasures afforded by the festivals of the year. And we still find byways, remote from intercourse with great cities, where a countryman will have no other measure of time at his disposal than the clock on the church tower of his hamlet, and must regulate his hours of labor by the course of the sun, the moon, or the stars. Solitary shepherds are still to be met on the heath who, in classic fashion, measure time by the foot-lengths of their own shadows. But who ever thinks, as he glances at his watch or at a calendar condensed into a few pages, of the thousands of years of the most zealous astronomical observations required to furnish both of these as we have them in our day? Who ever considers that this calendar, frequently coming to us in such unpretentious garb, represents one of the greatest achievements of human research and effort?—WITTICH *Die Schnelligkeit unseres Empfindens und Wollens (a Lecture)*, p. 6. (Translated for *Scientific Side-Lights.*)

3435. TIME, LAPSE OF, MADE SENSIBLE BY DWELLING ON IT—*Preoccupation Seems to Shorten.*—Our estimate of time as it passes is commonly said to depend on the amount of consciousness which we are giving to the fact of its transition. Thus, when the mind is unoccupied and suffering from ennui, we feel time to move sluggishly. On the other hand, interesting employment, by diverting the thoughts from time, makes it appear to movè at a more rapid pace. This fact is shown in the common expressions which we employ, such as "to kill time," and the German *Langeweile.* Similarly, it is said that when we are eagerly anticipating an event, as the arrival of a friend, the mere fact of dwelling on the interval makes it appear to swell out. This view is correct in the main.—SULLY *Illusions*, ch. 10, p. 250. (A., 1897.)

3436. TIME, MAN'S FIRST MEASURE OF—*Months and Weeks Determined by the Moon.*—It was these phases and aspects of the moon which formerly gave birth to the custom of measuring time by months, and by weeks of seven days, on account of the return of the moon's phases in a month, and because the moon appears about every seven days, so to say, under a new form. Such was the first measure of time; there was not in the sky any signal of which the differences, the alternations, and the epochs were more remarkable. Families met together at a time fixed by some lunar phase.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 2, p. 100. (A.)

3437. TIME OCCUPIED BY SENSATION AND VOLITION—*Illustration of Whale Wounded in the Tail.*—The time occupied by a sensation and subsequent volition has been measured in circumstances where there were no conflicting impulses. This is done by ascertaining the time elapsing between the sensation of a signal and the answering by the hand. A comparison is made between two situations; one where the person is prepared beforehand, by knowing where he is to be affected and what part is to move, in which case the attention is turned upon the proper points. The other situation is where a person does not know which part is to be struck, and which part is to be moved; in this last case he has to exercise an active judgment or consideration, and the difference of time is about the $\frac{1}{14}$th of a second. Two persons are separated by a screen; one is to utter a syllable and the other to repeat it as soon as possible. If the syllable has been agreed upon, the interval of repetition occupies from one-sixth to one-fourth of a second; if it is not agreed upon, the interval is one-twelfth of a second more. The example is put by M. Du Bois Raymond of a whale, ninety feet long, struck in the tail by a harpoon; one second would be occupied in transmitting the impression to the brain; a fraction of a second, say one-tenth, in traversing the brain; a full second in returning the motor impulse, so that the boat would have upward of two seconds for escaping the danger.—BAIN *Mind and Body*, ch. 3, p. 10. (Hum., 1880.)

3438. TIME, THE BEGINNING OR END OF, INCONCEIVABLE—We are altogether unable to conceive time as commencing; . . . we are conscious to ourselves of nothing more clearly than that it would be equally possible to think without thought as to construe to the mind an absolute commencement or an absolute termination of time. . . . Goad imagination to the utmost, it still sinks paralyzed within the bounds of time, and time survives as the condition of the thought itself in which we annihilate the universe.—HAMILTON *Metaphysics*, lect. 38, p. 529. (G. & L., 1859.)

3439. TIME WORKS VAST RESULTS WITH TRIFLING FORCE—*Crevasses of Glacier.*—[Upon the glacier] an explosion is heard. . . . The sound is repeated, several shots being fired in quick succession. . . . After an hour's strict search we discover the cause of the reports. They announce the birth of a crevasse. Through a pool upon the glacier we notice air-bubbles ascending, and find the bottom of the pool crossed by a narrow crack, from which the bubbles issue. Right and left from this pool we trace the young fissure through long distances. It is sometimes almost too feeble to be seen, and at no place is it wide enough to admit a knife-blade. . . . The great and gaping chasms on and above the ice-falls of the Géant and the Talèfre begin as narrow cracks, which open gradually to crevasses. We are thus taught in an instructive and impressive way that appearances suggestive of very violent action may really be produced by processes so slow as to require refined observations to detect them. In the production of natural phenomena two things always come into play, the intensity of the acting force and the time during which it acts. Make the intensity great and the time small, and you have sudden convulsion; but precisely the same apparent effect may be produced by making the intensity small and the time great.—TYNDALL *Forms of Water*, p. 98. (A., 1899.)

3440. TIME-KEEPING IN SLEEP—*Waking at a Specified Hour—Power Varies in Different Persons—Unconscious Chronometry.*—There are many individuals who have the power of determining, at the time of going to rest, the hour at which they shall awake, and who arouse themselves at the precise time fixed upon—not from the restless sleep which such a determination would ordinarily induce (the writer, for example, would be prevented by it from obtaining an hour of continuous repose through the whole night), but from a slumber that remains unbroken until the appointed time arrives. This fact . . . seems to point to a kind of *unconscious chronometry*, which is in some way connected with the sequence of the organic functions. . . . The whole series of such phenomena has a peculiar interest, in connection with the pretensions advanced by mesmerizers to exercise a special control over the "subjects" of their manipulations.—CARPENTER *Mental Physiology*, bk. ii, ch. 15, p. 583. (A., 1900.)

3441. TIMIDITY TAUGHT YOUNG BIRDS BY ELDERS—During the past summer, while living near Kew Gardens, I watched the sparrows a great deal, and fed forty or fifty of them every day from a back window. The bread and seed were thrown on to a low roof just outside the window, and I noticed that the young birds when first able to fly were always brought by the parents to this feeding-place, and that after two or three visits they would begin to come of their own accord. At such times they would venture quite close to me, showing as little suspicion as young chickens. The adults, however, altho so much less shy than birds of other species, were extremely suspicious, snatching up the bread and flying away; or, if they remained, hopping about in a startled manner, craning their necks to view me, and making so many gestures and motions, and little chirps of alarm, that presently the young would become infected with fear. The lesson was taught them in a surprisingly short time; their suspicion was seen to increase day by day, and about a week later they were scarcely to be distinguished in behavior from the adults. It is plain that, with these little birds, fear of man is an associate feeling, and that, unless it had been taught them, his presence would trouble them as little as does that of horse, sheep, or cow.—HUDSON *Naturalist in La Plata*, ch. 5, p. 84. (C. & H., 1895.)

3442. TOMBSTONES OF ANCIENT ANIMALS—*Limestone Largely Composed of Sea-shells.*—Limestone strata in the crust of the earth are found in all the periods of the earth's formation. All forms of sea-shells that were once the homes of animal life are constructed of this compound; and in the later formations of limestone, in the Secondary and Tertiary periods, we find this rock to be made up almost entirely of marine shells, some of them microscopic in size. The earlier or older formations of limestone that are found deeper down in the earth's crust are less mingled with these marine shells. This comes from the fact that the first deposition of limestone strata occurred before the later forms of sea life had developed. Whatever signs of life are found in these lower stratifications are of the very lowest order. It is not to be understood that animal life is a necessary factor in the formation of limestone, but it has been an incidental feature which no doubt has been the chief means of gathering up from the water this compound and precipitating it into the great limestone strata that are everywhere found.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 2, p. 13. (F. H. & H., 1900.)

3443. TOOLS, ANCIENT INDIAN—*Provided with Carefully Wrought Handles—The Grip a Matter of Thought and Care.*—The ingenuity of the American mechanic in hafting his tools and bringing them to their work cannot be overlooked. In this study the archeologist must learn of the ethnologist. The study of hafting must take into consideration the grip and the attachment. The grip of the implement may be a part of the object itself, or it may be a separate piece fastened on. In the Eskimo scrapers, women's knives, men's knives, throwing-sticks, and harpoons, the greatest care was taken to have the grip so fit the hand and fingers that the greatest force and dexterity could be used in operating them.—MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology,* p. 74). (Sch. P. C.)

3444. TOOLS AND WEAPONS OF PRIMITIVE MAN — *Alike in Europe and America.*—The simple weapons of bone and stone found in America closely resemble those which occur in other countries. The flakes, hatchets, axes, arrow-heads, and bone implements are, for instance, very similar to those which occur in the Swiss lakes, if only we make allowance for the differences of material. . . . [There are many] simple forms, which may almost be said to be ubiquitous.—AVEBURY *Prehistoric Times,* ch. 8, p. 237. (A., 1900.)

3445. TOOLS FITTED TO ENVIRONMENT—*Habitat Determines Material and Uses.*—The tool of the artisan is fitted to the hand; but to the scrutinizing glance of the student it is just as nicely fitted to its environment, to the work which it has to perform, to the grade of industrial education which the owner has reached, to the genius of his people, and even to their language and mythology. The director of a large museum, on examining an implement new to him, is quite as likely to fix his attention upon the region, or the work to be done, or the standing of the owner, as upon his blood or nationality. The continent of America was largely the director of the arts of the aborigines.—MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology,* p. 70). (Sch. P. C.)

3446. TOUCH, SENSE OF, IN WORMS—*Shape of Objects Discovered.*—If worms are able to judge, either before drawing or after having drawn an object close to the mouths of their burrows, how best to drag it in, they must acquire some notion of its general shape. This they probably acquire by touching it in many places with the anterior extremity of their bodies, which serves as a tactile organ. It may be well to remember how perfect the sense of touch becomes in a man when born blind and deaf, as are worms. If worms have the power of acquiring some notion, however rude, of the shape of an object and of their burrows, as seems to be the case, they deserve to be called intelligent; for they then act in nearly the same manner as would a man under similar circumstances.—DARWIN *Formation of Vegetable Mould,* ch. 2, p. 28. (Hum., 1887.)

3447. TOWERS, SPIRES, AND PINNACLES OF ICE—*Nature's Architecture.*—When a glacier descends a precipice it may become broken and fall in detached blocks, thus forming veritable ice cascades; but the fragments unite again at the base of the cliffs and become reconsolidated, and the ice flows on as a continuous stream. At other times the descent is completely covered with ice so shattered as to be impassable, and presents all degrees of diversity between ice cascades and ice rapids. The places of steep descent in the floor of a névé frequently lead to the breaking of the snow and ice into cubical blocks of all dimensions up to hundreds of feet in diameter, which bear a striking resemblance to towers and other architectural forms, and add most attractive features to the scenery of glacier-covered regions. During night marches on the glaciers of Alaska, the writer could scarcely put aside the idea that these shadowy forms, partially illuminated by the northern twilight, were in reality the ruins of marble temples. In the lower portions of glaciers, where the ice is more solid and where surface melting is more rapid, the steep descents are marked by spires and pinnacles having extremely rugged and angular forms, separated by profound crevasses.—RUSSELL *Glaciers of North America,* int.. p. 10. (G. & Co., 1897.)

3448. TRACK OF VANISHED GLACIER—*Rocks Polished as by Lapidary.*—Rock surfaces that have been subjected to the grinding of an ice sheet, or crossed by even a small Alpine glacier, are frequently found to be worn and the angles and prominences rounded and planed away. All weathered and oxidized portions of the preglacial surface are removed, and the fresh hard rock exhibits a polish approaching that given by marble-workers to finished monuments. The hardest and finest-grained rocks receive the most brilliant polish. Limestone, granite, and quartzite, especially, are frequently so highly burnished that they glitter in the sunlight with dazzling brilliancy. On such surfaces there are usually scratches and grooves, frequently in long, parallel lines, which show the direction in which the ice moved over them. These markings vary in size from delicate, hairlike lines, such as might be made by a crystal point, to heavy grooves and gouges, a foot and sometimes several feet deep, which frequently run in one general direction for many yards and even several rods, and indicate by their straightness and evenness that the engine which made them was one of great power

and moved steadily in a continuous direction.—RUSSELL *Glaciers of North America*, int., p. 20. (G. & Co., 1897.)

3449. TRACTS, DEFINITE, IN BRAIN, FOR SPECIAL SERVICE—*Loss of the Power of Speech and of Writing—Other Faculties May Remain Unimpaired.*—Victims of motor aphasia generally have other disorders. One which interests us in this connection has been called *agraphia:* they have lost the power to write. They can read writing and understand it; but either cannot use the pen at all or make egregious mistakes with it. . . . The symptom may exist when there is little or no disability in the hand for other uses. If it does not get well, the patient usually . . . learns to write with his left hand. In other cases . . . the patient can write both spontaneously and at dictation, but cannot read even what he has himself written! All these phenomena are now quite clearly explained by separate brain-centers for the various feelings and movements, and tracts for associating these together.—JAMES *Psychology*, vol. i, ch. 2, p. 40. (H. H. & Co., 1899.)

3450. TRADE, PRIMITIVE, EVIDENCES OF—*Stone and Metal Bartered over Thousands of Miles.*—Till 1884 no European locality of jade or nephrite was known, and tho it has now been discovered in Silesia, and described by Traube, yet, as he points out, the European implements do not belong to the same variety, and were not therefore derived from that locality . . . ; they must therefore have passed from tribe to tribe by a sort of barter. . . .

Other facts of a similar nature are on record. Thus Messrs. Squier and Davis tell us that in the tumuli of the Mississippi Valley we find "side by side, in the same mounds, native copper from Lake Superior, mica from the Alleghanies, shells from the Gulf, and obsidian (perhaps porphyry) from Mexico." Fair representations of the seacow or manatee are found a thousand miles from the shores inhabited by that animal, and shells of the large tropical *Pyrula perversa* are met with in the tumuli round the great lakes, two thousand miles from home. —AVEBURY *Prehistoric Times*, ch. 4, p. 76. (A., 1900.)

3451. TRADITION OFTEN A TRUTHFUL MEMORIAL — *Chief's Stone Seat Found as Related—A Treasured Staff of Office.*—There are still peoples left whose whole history is the tradition of their ancestors. Thus the South Sea Islanders, who till quite lately had no writing, were intelligent barbarians, much given to handing down recollections of bygone days, and in one or two cases, which it has been possible to test among them, it seems as tho memory may really keep a historical record long and correctly. It is related by Mr. Whitmee, the missionary, that in the island of Rotuma there was a very old tree, under which, according to tradition, the stone seat of a famous chief had been buried; this tree was lately blown down, and, sure enough, there was a stone seat under its roots, which must have been out of sight for centuries. In the Ellice group, the natives declared that their ancestors came from a valley in the distant island of Samoa generations before, and they preserved an old worm-eaten staff, pieced to hold it together, which in their assemblies the orator held in his hand as the sign of having the right to speak; this staff was lately taken to Samoa, and proved to be made of wood that grew there, while the people of the valley in question had a tradition of a great party going out to sea exploring, who never came back.—TYLOR *Anthropology*, ch. 15, p. 374. (A., 1899.)

3452. TRADITION, PERUVIAN, OF DELUGE—*Parallel to Story of Genesis.*—All authentic accounts cease when we ascend to the era of the conquest of Peru by the Spaniards. The ancient Peruvians, altho far removed from barbarism, were without written annals, and therefore unable to preserve a distinct recollection of a long series of natural events. They had, however, according to Antonio de Herrera, who, in the beginning of the seventeenth century, investigated their antiquities, a tradition, "that many years before the reign of the Incas, at a time when the country was very populous, there happened a great flood; the sea breaking out beyond its bounds, so that the land was covered with water and all the people perished. To this the Guacas, inhabiting the vale of Xausca, and the natives of Chiquito, in the province of Callao, add that some persons remained in the hollows and caves of the highest mountains, who again peopled the land. Others of the mountain people affirm that all perished in the deluge, only six persons being saved on a float, from whom descended all the inhabitants of that country."—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 502. (A., 1854.)

3453. TRADITION UNTRUSTWORTHY—*Tasman and De Soto Forgotten in Lands They Discovered.*—Tradition [will not] supply the place of history. At best it is untrustworthy and short lived. Thus in 1770 the New Zealanders had no recollection of Tasman's visit. Yet this took place in 1643, less than 130 years before, and must have been to them an event of the greatest possible importance and interest. In the same way the North-American Indians soon lost all tradition of De Soto's expedition, altho "by its striking incidents it was so well suited to impress the Indian mind."—AVEBURY *Prehistoric Times*, ch. 13, p. 404. (A., 1900.)

3454. TRADITIONS OF ANCIENT DELUGES—*China's Flood Perhaps a Local Inundation.*—The great flood of the Chinese, which their traditions carry back to the

period of Yaou, something more than 2,000 years before our era, has been identified by some persons with the universal deluge described in the Old Testament; but according to Mr. Davis. who accompanied two of our embassies to China, and who has carefully examined their written accounts, the Chinese cataclysm is therein described as interrupting the business of agriculture, rather than as involving a general destruction of the human race. The great Yu was celebrated for having "opened nine channels to draw off the waters," which "covered the low hills and bathed the foot of the highest mountains." Mr. Davis suggests that a great derangement of waters of the Yellow River, one of the largest in the world, might even now cause the flood of Yaou to be repeated, and lay the most fertile and populous plains of China under water. In modern times the bursting of the banks of an artificial canal, into which a portion of the Yellow River has been turned, has repeatedly given rise to the most dreadful accidents, and is a source of perpetual anxiety to the government. It is easy, therefore, to imagine how much greater may have been the inundation if this valley was ever convulsed by a violent earthquake.—LYELL *Principles of Geology*, bk. i, ch. 2, p. 7. (A., 1854.)

3455. TRAINING, SCIENTIFIC—*Its Educational Value.*—I have already expressed a favorable opinion of the old classical methods of mind-training, but that opinion does not exclude the idea of other methods which may be equally as valuable. Of one thing we may be quite certain, and that is that in the habits of careful observation and recording, which are necessary to the study of any science, the perceptive faculties of the mind receive a training which cannot be regarded as inferior to that secured by any other method. In considering the data which are obtained by perception, the reflective faculties also obtain a training of the highest value. Teachers of science, therefore, must not be regarded wholly from a technical point of view, but must be entitled to a proper recognition from the pedagogic side.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 50).

3456. TRANSCENDENTALISM IN SCIENCE — *Matter Analyzed into Force.* — There are eddies in every stream—eddies where rubbish will collect and circle for a time. But the ultimate bearing of scientific truth cannot be mistaken. Nothing is more remarkable in the present state of physical research than what may be called the transcendental character of its results. And what is transcendentalism but the tendency to trace up all things to the relation in which they stand to abstract ideas? And what is this but to bring all physical phenomena nearer and nearer into relation with the phenomena of mind? The old speculations of philosophy which cut the ground from materialism by showing how little we know of matter are now being daily reenforced by the subtle analysis of the physiologist, the chemist, and the electrician. Under that analysis matter dissolves and disappears, surviving only as the phenomena of force; which again is seen converging along all its lines to some common center—"sloping through darkness up to God."—ARGYLL *Reign of Law*, ch. 2, p. 70. (Burt.)

3457. TRANSFER OF THOUGHT IMPOSSIBLE—*Signs Awaken Corresponding Idea—No Resemblance between Thought and Sign.*—Consider, with Professor Bowne, what happens when two people converse together and know each other's mind.

"No thoughts leave the mind of one and cross into the mind of the other. When we speak of an exchange of thought, even the crudest mind knows that this is a mere figure of speech. . . . To perceive another's thought we must construct his thought within ourselves; . . . this thought is our own and is strictly original with us. At the same time we owe it to the other; and if it had not originated with him, it would probably not have originated with us. But what has the other done? . . . This: by an entirely mysterious world-order, the speaker is enabled to produce a series of signs which are totally unlike [the] thought, but which, by virtue of the same mysterious order, act as a series of incitements upon the hearer, so that he constructs within himself the corresponding mental state. The act of the speaker consists in availing himself of the proper incitements. The act of the hearer is immediately only the reaction of the soul against the incitement. . . . All communion between finite minds is of this sort." —JAMES *Psychology*, vol. i, ch. 8, p. 219. (H. H. & Co., 1899.)

3458. TRANSFIGURATION OF PHENOMENA BY LAW—*Need of Law in Spiritual World.*—I confess that even when in the first dim vision the organizing hand of law moved among the unordered truths of my spiritual world, poor and scantily furnished as it was, there seemed to come over it the beauty of a transfiguration. The change was as great as from the old chaotic world of Pythagoras to the symmetrical and harmonious universe of Newton. My spiritual world before was a chaos of facts; my theology a Pythagorean system trying to make the best of phenomena apart from the idea of law. I make no charge against theology in general. I speak of my own. And I say that I saw it to be in many essential respects centuries behind every department of science I knew. It was the one region still unpossessed by law. I saw then why men of science distrust theology; why those who have learned to look upon law as au-

thority grow cold to it—it was the great exception.—DRUMMOND *Natural Law in the Spiritual World*, pref., p. 9. (H. Al.)

3459. TRANSFORMATION BY CHANGED CONDITIONS—*Worker Changed to Queen—Potentiality To Be Accounted for.*—The most remarkable example with which I am acquainted, of the effect of physical conditions in modifying the developmental process, is that which is seen in the economy of the hive-bee. It is well known that whenever, from any cause, a community wants a queen, a worker grub at an early stage is selected; a "royal cell" is constructed round it, several ordinary cells being demolished for the purpose, and their contained grubs killed; the selected grub is fed with "royal jelly" instead of with "bee-bread"; and (it seems probable) a higher temperature is maintained by the incessant activity of the bees which cluster about the royal nursery. In due time a perfect "queen" comes forth, differing from the "worker" not merely in the completeness of its reproductive apparatus, but in the conformation of its jaws and antennæ, the absence of "pollen-baskets" on the thighs, and yet more remarkably in its instincts. Now it is obviously no explanation of this extraordinary transformation to say that every worker grub is a "potential" queen, because the attributing this "potentiality" to it is only another way of expressing the fact that it can be so transformed. The existence of the "potentiality," and of the wonderful instinct that leads the worker bees to act upon it, are not less evidences of "design," because physical agencies are needed to call them into exercise.—CARPENTER *Nature and Man*, lect. 15, p. 440. (A., 1889.)

3460. TRANSFORMATION, GRADUAL, FROM ANCIENT TO MODERN TYPE—*Crocodile the Heir of a Long Succession.*—The crocodiles are animals which, as a group, have a very vast antiquity. They abounded ages before the chalk was deposited; they throng the rivers in warm climates at the present day. There is a difference in the form of the joints of the backbone, and in some minor particulars, between the crocodiles of the present epoch and those which lived before the chalk. . . . But each epoch has had its peculiar crocodiles, tho all, since the chalk, have belonged to the modern type, and differ simply in their proportions, and in such structural particulars as are discernible only to trained eyes. How is the existence of this long succession of different species of crocodiles to be accounted for? Only two suppositions seem to be open to us—either each species of crocodile has been specially created, or it has arisen out of some preexisting form by the operation of natural causes. Choose your hypothesis; I have chosen mine. I can find no warranty for believing in the distinct creation of a score of successive species of crocodiles in the course of countless ages of time. Science gives no countenance to such a wild fancy; nor can even the perverse ingenuity of a commentator pretend to discover this sense, in the simple words in which the writer of Genesis records the proceedings of the fifth and sixth days of the creation. On the other hand, I see no good reason for doubting the necessary alternative, that all these varied species have been evolved from preexisting crocodilian forms, by the operation of causes as completely a part of the common order of Nature as those which have effected the changes of the inorganic world.—HUXLEY *Lay Sermons*, serm. 9, p. 200. (G. P. P., 1899.)

3461. TRANSFORMATION OF ENGLAND THROUGH THE DISCOVERY OF COAL—*Possible Effect of Its Exhaustion.*—Three hundred years ago the sun, looking down on the England of our forefathers, saw a fair land of green woods and quiet waters, a land unvexed with noisier machinery than the spinning-wheel or the needles of the "free maids that weave their threads with bones." Because of the coal which has been dug from its soil he sees it now soot-blackened, furrowed with railway-cuttings, covered with noisy manufactories, filled with grimy operatives, while the island shakes with the throb of coal-driven engines, and its once quiet waters are churned by the wheels of steamships. Many generations of the lives of men have passed to make the England of Elizabeth into the England of Victoria; but what a moment this time is, compared with the vast lapse of ages during which the coal was being stored! What a moment in the life of the "all-beholding sun," who in a few hundred years—his gift exhausted and the last furnace fire out—may send his beams through rents in the ivy-grown walls of deserted factories, upon silent engines brown with rust, while the mill-hand has gone to other lands, the rivers are clean again, the harbors show only white sails, and England's "black country" is green once more! To America, too, such a time may come, tho at a greatly longer distance.—LANGLEY *New Astronomy*, ch. 4, p. 115. (H. M. & Co., 1896.)

3462. TRANSFORMATION OF PAST INTO PRESENT—*The Past of the Stars Is the Terrestrial Present.*—We have seen that light is not transmitted instantaneously from one point to another, but gradually, like everything movable; that it flies at the rate of 186,000 miles a second, or 11 millions of miles in one minute; that it takes more than eight minutes to pass over the distance which separates us from the sun, four hours to come from Neptune, and four years and four months to come from the nearest star, etc.

There is here, then, a surprising transformation of the past into the present. For the star observed, it is the past—already vanished. For the observer, it is the pres-

ent, the now. The past of a star is strictly and positively the present of the observer. As the aspect of worlds changes from year to year, from one season to another, and almost from one day to the next, we can represent this aspect as escaping into space and advancing in infinitude to reveal itself to the eyes of distant beholders. Each aspect is followed by another, and so on successively; and it is as if a series of waves bearing from afar the past of worlds should become present to observers ranged along its passage! What we believe we see now in the stars is already past; and what is now being accomplished we do not yet see.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 616. (A.)

3463. TRANSFORMATION OF RAILWAY INTO TELEPHONE CIRCUIT—Another striking illustration [of electrical conduction without wires] is furnished by Professor Blake, of Brown University, . . . who talked with a friend for some distance along a railway (using the two lines of rails for the telephonic circuit), hearing at the same time the Morse signals passing along the telegraph wires overhead.—FAHIE *Wireless Telegraphy*, p. 85. (D. M. & Co., 1900.)

3464. TRANSFORMATION OF UNSEEN PRODUCTS OF COMBUSTION—*Beauty and Warmth Arise from Destruction.*—[The floating] smoke, tho so long unnoticed by man, was not overlooked by the Author of Nature. It is a part of his grand and beneficent design in the scheme of organic nature. No sooner do the products of that wood burning on the hearth escape into the free expanse of the outer air, than a new cycle of changes begins. The carbonic dioxid and the aqueous vapor, after roving at liberty for a time, are absorbed by the leaves of some wide-spreading tree, smiling in the sunshine, and in the tiny laboratory of their green cells are worked up by those wonderful agents, the sun-rays, into new wood, absorbing from the sun a fresh supply of power, which is destined, perhaps, to shed warmth and light around the fireside of a future generation.—COOKE *Religion and Chemistry*, ch. 3, p. 80. (A., 1897.)

3465. TRANSFORMATION WROUGHT BY SUNLIGHT—*Waste Products Utilized—A Lily in the Black Hole of Calcutta.*—The sunbeam . . . does what our wisest chemistry cannot do: it takes the burned-out ashes and makes them anew into green wood; it takes the close and breathed-out air and makes it sweet and fit to breathe by means of the plant, whose food is the same as our poison. With the aid of sunlight a lily would thrive on the deadly atmosphere of the "black hole of Calcutta"; for this bane to us, we repeat, is vital air to the plant, which breathes it in through all its pores, bringing it into contact with the chlorophyl, its green blood, which is to it what the red blood is to us; doing almost everything, however, by means of the sunray, for if this be lacking, the oxygen is no longer set free or the carbon retained, and the plant dies. This too brief statement must answer instead of a fuller description of how the sun's energy builds up the vegetable world.—LANGLEY *New Astronomy*, ch. 3, p. 73. (H. M. & Co., 1896.)

3466. TRANSFORMATION WROUGHT BY WORMS—*The "Wilderness Turned into a Fruitful Field"—Beneficent Work of Unconsidered or Despised Organisms.*—A field . . . , which was last plowed in 1841, was then harrowed and left to become pasture-land. For several years it was clothed with an extremely scant vegetation, and was so thickly covered with small and large flints (some of them half as large as a child's head) that the field was always called by my sons "the stony field." When they ran down the slope the stones clattered together. I remember doubting whether I should live to see these larger flints covered with vegetable mold and turf. But the smaller stones disappeared before many years had elapsed, as did every one of the larger ones after a time; so that after thirty years (1871) a horse could gallop over the compact turf from one end of the field to the other, and not strike a single stone with his shoes. To any one who remembered the appearance of the field in 1842, the transformation was wonderful. This was certainly the work of the worms, for tho castings were not frequent for several years, yet some were thrown up month after month, and these gradually increased in numbers as the pasture improved. In the year 1871 a trench was dug on the above slope, and the blades of grass were cut off close to the roots, so that the thickness of the turf and of the vegetable mold could be measured accurately. The turf was rather less than half an inch, and the mold, which did not contain any stones, 2½ inches in thickness. Beneath this lay coarse, clayey earth full of flints, like that in any of the neighboring plowed fields. This coarse earth easily fell apart from the overlying mold when a spit was lifted up. The average rate of accumulation of the mold during the whole thirty years was only .083 inch per year (*i. e.*, nearly one inch in twelve years); but the rate must have been much slower at first, and afterwards considerably quicker.—DARWIN *Formation of Vegetable Mould*, ch. 3, p. 41. (Hum., 1887.)

3467. TRANSITION FROM BIRDS TO REPTILES—*Fossil Connecting-links Are Found.*—When compared with other animals, birds are found to occupy second place in the scale of life. They stand between mammals and reptiles, and are more closely related to the latter than to the former. In fact, certain extinct birds so clearly connect living birds with reptiles that these two classes are sometimes placed in one

group—the *Sauropsida*. . . . There is good evidence for the belief that birds have descended from reptilian ancestors. This evidence consists of the remains of fossil birds, some of which show marked reptilian characters, and are toothed.—CHAPMAN *Bird-Life*, ch. 1, p. 1. (A., 1900.)

3468. TRANSITION FROM BRONZE TO IRON AGE—*Barbarism Surpassing Civilization.*—It is especially difficult to determine the positive date when any nation made the transition from the Bronze to the Iron Age, and practically impossible to do so in the cases of people who either inhabited countries where iron does not abound, or who never acquired the art of obtaining it. In such event, the substitution of implements of iron necessarily imported from other countries for the native ones of bronze, to which the population had become accustomed by ages of use, was an exceedingly slow process, retarded by the mental inertia of the times, and often by national pride in home customs and handiwork. Hence arises the seeming anomaly that among people far advanced in civilization the general use of iron can be recognized only at a comparatively late period in their history; while among barbarians, incomparably below them in intellectual attainments, we find evidence of its employment at immensely earlier periods. In Denmark, for example, the Age of Iron corresponds to that of the beech-tree. Hesiod, writing in 850 B. C., speaks of the time when "men wrought in brass, when iron did not exist"; and Homer, altho frequently referring to weapons and implements of bronze, mentions iron but rarely. The Aztecs, at the time of the Conquest, knew nothing of the metal, altho their soil was impregnated with it. The Peruvians, under the same natural conditions, were equally ignorant.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 1, p. 21. (J. W., 1898.)

3469. TRANSITION FROM NATURAL TO SPIRITUAL—*Like That from Mineral to Organic Life.*—Why a virtuous man should not simply grow better and better until in his own right he enter the kingdom of God is what thousands honestly and seriously fail to understand. Now philosophy cannot help us here. Her arguments are, if anything, against us. But science answers to the appeal at once. If it be simply pointed out that this is the same absurdity as to ask why a stone should not grow more and more living till it enters the organic world, the point is clear in an instant.—DRUMMOND *Natural Law in the Spiritual World*, essay 1, p. 71. (H. Al.)

3470. TRANSITION FROM TYPE TO TYPE—*Species United by Steady Gradation of Varieties.*—In the small forest region of Oahu, one of the Sandwich Islands, there have been found about 175 species of land-shells represented by 700 or 800 varieties; and we are told by the Rev. J. T. Gulick, who studied them carefully, that "we frequently find a genus represented in several successive valleys by allied species, sometimes feeding on the same, sometimes on different plants. In every such case the valleys that are nearest to each other furnish the most nearly allied forms; and a full set of the varieties of each species presents a minute gradation of forms between the more divergent types found in the more widely separated localities."—WALLACE *Darwinism*, ch. 3, p. 29. (Hum.)

3471. TRANSITION, GRADUAL, OF GROUPS AND SPECIES IN GEOLOGIC TIMES—If there be any result which has come more clearly out of geological investigation than another, it is that the vast series of extinct animals and plants is not divisible, as it was once supposed to be, into distinct groups, separated by sharply marked boundaries. There are no great gulfs between epochs and formations—no successive periods marked by the appearance of plants, of water animals, and of land animals, *en masse*. Every year adds to the list of links between what the older geologists supposed to be widely separated epochs. . . . This truth is further illustrated in a most interesting manner by the impartial and highly competent testimony of M. Pictet, from whose calculations of what percentage of the genera of animals, existing in any formation, lived during the preceding formation, it results that in no case is the proportion less than one-third, or 33 per cent.; . . . other formations not uncommonly exhibit 60, 80, or even 94 per cent. of genera in common with those whose remains are embedded in their predecessor.—HUXLEY *Lay Sermons*, serm. 12, p. 280. (G. P. P., 1899.)

3472. TRANSITION, SCIENCE IN STATE OF—*Miasma and Malaria but Partially Understood.*—The term "miasm" has had an extensive and somewhat diffuse application in medical science. It may happen in the future that typhoid will be classified strictly as a miasmatic disease. But at present, in the transition state of the science, it would hardly be justifiable to classify typhoid with a typically miasmatic disease like malaria. Yet it is clear that mention should here be made of a group of diseases of which malaria is the type, and of which the tropics generally are the native land. The bacterial etiology of the group is by no means worked out. The cause of malaria alone is not yet a closed subject. However the details of the etiology of this group finally arrange themselves, there is little doubt of two facts, viz., the diseases are probably produced by bacteria or allied protozoa, and soil plays an important part in their production.—NEWMAN *Bacteria*, ch. 5, p. 177. (G. P. P., 1899.)

3473. TRANSITORINESS OF HUMAN MEMORIALS—We can foresee no limit to the perpetuation of some of the memorials of man, which are continually entombed in the bowels of the earth or in the bed of the ocean. . . .

Yet it is no less true, as a late distinguished philosopher [Davy] has declared, "that none of the works of a mortal being can be eternal." They are in the first place wrested from the hands of man, and lost as far as regards their subserviency to his use, by the instrumentality of those very causes which place them in situations where they are enabled to endure for indefinite periods. And even when they have been included in rocky strata, when they have been made to enter, as it were, into the solid framework of the globe itself, they must nevertheless eventually perish; for every year some portion of the earth's crust is shattered by earthquakes, or melted by volcanic fire, or ground to dust by the moving waters on the surface. "The river of Lethe," as Bacon eloquently remarks, "runneth as well above ground as below."—LYELL *Principles of Geology*, bk. iii, ch. 48, p. 764. (A., 1854.)

3474. TRANSITORINESS OF LAND-FORMATIONS — *Islands Built Up and Destroyed in the Ganges.*—Major R. H. Colebrooke, in his account of the course of the Ganges, relates examples of the rapid filling up of some of its branches, and the excavation of new channels, where the number of square miles of soil removed in a short time (the column of earth being 114 feet high) was truly astonishing. Forty square miles, or 25,600 acres, are mentioned as having been carried away, in one place, in the course of a few years. The immense transportation of earthy matter by the Ganges and Brahmaputra is proved by the great magnitude of the islands formed in their channels during a period far short of that of a man's life. Some of these, many miles in extent, have originated in large sand-banks thrown up round the points at the angular turning of the rivers, and afterwards insulated by breaches of the streams. Others, formed in the main channel, are caused by some obstruction at the bottom. A large tree or a sunken boat is sometimes sufficient to check the current, and cause a deposit of sand, which accumulates till it usurps a considerable portion of the channel. The river then undermines its banks on each side to supply the deficiency in its bed, and the island is afterwards raised by fresh deposits during every flood. In the great gulf below Luckipour, formed by the united waters of the Ganges and Megna, some of the islands, says Rennell, rival in size and fertility the isle of Wight. While the river is forming new islands in one part, it is sweeping away old ones in others. Those newly formed are soon overrun with reeds, long grass, the *Tamarix Indica*, and other shrubs, forming impenetrable thickets, where the tiger, the rhinoceros, the buffalo, deer, and other wild animals, take shelter. It is easy, therefore, to perceive that both animal and vegetable remains may occasionally be precipitated into the flood and become embedded in the sediment which subsides in the delta.—LYELL *Principles of Geology*, bk. ii, ch. 18, p. 277. (A., 1854.)

3475. TRANSITORINESS OF OUR UNIVERSE—*Some Greater All-embracing Reality.*—These impressions are strengthened rather than weakened when we come back from the outer universe to our own little solar system; for every process which we know tends to the dissipation, or rather the degradation, of heat, and seems to point, in our present knowledge, to the final decay and extinction of the light of the world. In the words of one of the most eminent living students of our subject, "The candle of the sun is burning down, and, as far as we can see, must at last reach the socket. Then will begin a total eclipse which will have no end.

'Dies iræ, dies illa,
Solvet sæclum in favilla.' "

Yet tho it may well be that the fact itself here is true, it is possible that we draw the moral to it unawares, from an unacknowledged satisfaction in the idea of the vastness of the funeral pyre provided for such beings as ourselves, and that it is pride, after all, which suggests the thought that when the sun of the human race sets, the universe will be left tenantless, as a body from which the soul has fled. Can we not bring ourselves to admit that there may be something higher than man and more enduring than frail humanity, in some sphere in which our universe, conditioned as it is in space and time, is itself embraced, and so distrust the conclusions of man's reason where they seem to flatter his pride?—LANGLEY *The New Astronomy*, ch. 8, p. 249. (H. M. & Co., 1896.)

3476. TRANSMISSION OF RADIANT HEAT—*Adventure on Railroad—Power of Unseen Forces.*—I once had an opportunity to observe the wonderful rapidity with which light and radiant heat are transmitted through glass, which is transparent to both. I was at Vancouver, at the terminus of the Canadian Pacific Railway, on Burrard Inlet. We started for Winnipeg about noon, and six miles out the train was stopped by a burning woodpile of large dimensions within a few feet of the track. After two hours of waiting the wood had been reduced to a huge pile of glowing coals. The conductor concluded to run past at a high rate of speed; so backing up about one-half mile they put on a full head of steam and ran past the fire at a tremendous speed. I was in a stateroom, and the passageway around it was between me and the fire, so that the heat and light had to pass through two win-

dows before it reached me. I stood in the stateroom, looking in the direction of the fire, so as to get a glimpse of it as we ran by. The time that my face was exposed was only a small fraction of a second, and the heat had to come through the glass of two windows some distance apart, and yet my face was burned to redness. The glass was not heated, but the sides of the cars were burned into blisters. The one was a transparent and the other an opaque substance.—ELISHA GRAY *Nature's Miracles,* vol. ii, ch. 23, p. 194. (F. H. & H., 1900.)

3477. TRANSMISSION OF RETRIEVER'S INSTINCT — *Heredity of Acquired Characters.*—The fixed and deliberate stand of the pointer has with propriety been regarded as a mere modification of a habit, which may have been useful to a wild race accustomed to wind game, and steal upon it by surprise, first pausing for an instant in order to spring with unerring aim. The faculty of the retriever, however, may justly be regarded as more inexplicable and less easily referable to the instinctive passions of the species. M. Majendie, says a French writer in a recently published memoir, having learned that there was a race of dogs in England which stopped and brought back game of their own accord, procured a pair, and having obtained a whelp from them, kept it constantly under his eyes until he had an opportunity of assuring himself that, without having received any instruction, and on the very first day that it was carried to the chase, it brought back game with as much steadiness as dogs which had been schooled into the same maneuver by means of the whip and collar. [See HEREDITY OF ACQUIRED CHARACTERS.]—LYELL *Principles of Geology,* bk. iii, ch. 35, p. 594. (A., 1854.)

3478. TRANSPARENCY NEVER PERFECT—*A Sufficient Depth of Water Absorbs All Light—Increase of Quantity Reverses Result.*—All bodies, even the most transparent, are more or less absorbent of light. Take the case of water: in small quantities it does not sensibly affect light. A glass cell of clear water interposed in the track of our beam does not perceptibly change any one of the colors of the spectrum derived from the beam. Still absorption, tho insensible, has here occurred, and to render it sensible we have only to increase the depth of the water through which the light passes. Instead of a cell an inch thick let us take a layer ten or fifteen feet thick; the color of the water is then very evident. By augmenting the thickness we absorb more of the light, and by making the thickness very great we absorb the light altogether. Lampblack or pitch can do no more, and the only difference between them and water is that a very small depth in their case suffices to extinguish all the light. The difference between the highest known transparency and the highest known opacity is one of degree merely.—TYNDALL *Lectures on Light,* lect. 1, p. 35. (A., 1898.)

3479. TRANSPORTATION BY STAGES—*Nature's Ice-boats—Locust-seeds Borne on Wings of Wind.*—And the wind is sure to come along, a slight breeze to-day tossing the half-pod a few feet, leaving it perhaps to be again and again moved farther forward. The writer has seen these half-pods [of the locust] transported by this means more than a block. But many of the pods stick to the limbs till winter comes. Then a breeze tears off a few pods and they fall on the snow, which has filled up all the crevices in the grass and between the dead leaves and rubbish. Each half-pod, freighted with every other seed, is admirably constructed; like an ice-boat, it has a sail always spread to the breeze. In this way there is often nothing to hinder some of the seeds from going a mile or two in a few minutes, now and then striking some object which jars off a seed or two. The seeds are very hard, and no doubt purposely so, that they may not be eaten by insects or birds; but once in moist soil the covering slowly swells and decays, allowing the young plant to escape. Thus the locust-seeds are provided with neither legs, wings, fins, nor do they advertise by brilliant hue and sweet pulp; but they travel in a way of their own, which is literally on the wings of the wind.—BEAL *Seed Dispersal,* ch. 5, p. 56. (G. & Co., 1898.)

3480. TRAVELING, THREE RAPID MODES OF—*Maximum Speed of Horse Nearly Reached—Possibilities of the Bicycle.*—It is a very interesting fact that three out of the four methods of rapid locomotion we now possess should have attained about the same maximum speed. The racehorse, the steamship, and the bicycle have each of them reached thirty miles an hour. The horse is, however, close upon, if it has not actually attained, its utmost limits: the bicycle can already beat the horse for long distances, and will certainly go at higher speeds for short ones; while the steamship will also go much quicker, tho how much no one can yet say. The greatest possibilities are with the bicycle driven by electric power or compressed air, by which means, on a nearly straight and fairly level asphalt track, no doubt fifty miles an hour will soon be reached.—WALLACE *The Wonderful Century,* ch. 1, p. 9. (D. M. & Co., 1899.)

3481. TREE, LIMITED CORRESPONDENCE OF, WITH ITS ENVIRONMENT—*Irresponsiveness Is Death.*—Different organisms correspond with [their] environment in varying degrees of completeness or incompleteness. At the bottom of the biological scale we find organisms which have only the most limited correspondence with their surroundings. A tree, for example, corresponds with the soil about its stem,

with the sunlight, and with the air in contact with its leaves. But it is shut off by its comparatively low development from a whole world to which higher forms of life have additional access. The want of locomotion alone circumscribes most seriously its area of correspondence, so that to a large part of surrounding Nature it may truly be said to be dead. So far as consciousness is concerned, we should be justified, indeed, in saying that it was not alive at all. The murmur of the stream which bathes its roots affects it not. The marvelous insect life beneath its shadow excites in it no wonder. The tender maternity of the bird which has its nest among its leaves stirs no responsive sympathy. It cannot correspond with those things. To stream and insect and bird it is insensible, torpid, dead. For this is death, this irresponsiveness.—DRUMMOND *Natural Law in the Spiritual World*, essay 4, p. 138. (H. Al.)

3482. TREE-FERNS OF THE TROPICS—*A Climate of Perpetual Spring.*—The form of ferns . . . , like that of grasses, also assumes nobler dimensions in the torrid regions of the earth, and the arborescent ferns, which frequently attain the height of above forty feet, have a palm-like appearance, altho their stem is thicker, shorter, and more rough and scaly than that of the palm. The leaf is more delicate, of a loose and more transparent texture, and sharply serrated on the margins. These colossal ferns belong almost exclusively to the tropics, but there they prefer the temperate localities. As in these latitudes diminution of heat is merely the consequence of an increase of elevation, we may regard mountains that rise 2,000 or 3,000 feet above the level of the sea as the principal seat of these plants. Arborescent ferns grow in South America, side by side with that beneficent tree whose stem yields the febrifuge bark, and both forms of vegetation are indicative of the happy region where reigns the genial mildness of perpetual spring.—HUMBOLDT *Views of Nature*, p. 230. (Bell, 1896.)

3483. TREES, COLOSSAL, OF TROPICS—*Crown Like Domed Cathedral—The Giant Must Dwell Alone.*—What attracted us chiefly were the colossal trees. The general run of trees had not remarkably thick stems; the great and uniform height to which they grow without emitting a branch was a much more noticeable feature than their thickness; but at intervals of a furlong or so a veritable giant towered up. Only one of these monstrous trees can grow within a given space; it monopolizes the domain, and none but individuals of much inferior size can find a footing near it. The cylindrical trunks of these larger trees were generally about 20 to 25 feet in circumference. Von Martius mentions having measured trees in the Pará district, belonging to various species (*Symphonia coccinea Lecythis sp.* and *Cratæva Tapia)*, which were 50 to 60 feet in girth at the point where they become cylindrical. The height of the vast column-like stems could not be less than 100 feet from the ground to their lowest branch. Mr. Leavens, at the sawmills, told me they frequently squared logs for sawing 100 feet long, of the Pao d'Arco and the Massaranduba. The total height of these trees, stem and crown together, may be estimated at from 180 to 200 feet; where one of them stands, the vast dome of foliage rises above the other forest-trees as a domed cathedral does above the other buildings in a city.—BATES *Naturalist on the River Amazon*, ch. 2, p. 635. (Hum., 1880.)

3484. TRIAL, FIERY, PRECIOUS RESULTS OF—*Gems the Products of Volcanoes—Crystallization through Pressure and Fierce Heat Gives Them All Their Value.*—Among the most interesting effects resulting from the extrusion of masses of incandescent rock, charged with water and various gases, through beds of limestone, clay, sandstone, etc., we may mention the production of those beautiful crystalline minerals which adorn our museums and are so highly prized as gems. By far the larger part of these beautiful minerals have been formed, directly or indirectly, by volcanic agencies.

These gems and beautiful minerals are, for the most part, substances of every-day occurrence, which entirely owe their beauty to the crystalline forms they have assumed. The diamond is crystallized carbon, the ruby and sapphire are crystallized aluminum, the amethyst and a host of other gems are crystallized silica; and in almost all cases the materials of gems are common and widely diffused; it is only in their finely crystalline condition that they are rare and therefore valuable.—JUDD *Volcanoes*, ch. 5, p. 146. (A., 1899.)

3485. TRIUMPH OF SCIENCE—*Cuvier Reproduces from Fragments Extinct Animals—Complete Specimens Later Verify His Theory.*—At length there was discovered at Montmartre an upper jaw of the same [unknown] animal, next a lower jaw, matching the upper one, and presently a whole head, with a few backbones, was brought to light. These were enough, with Cuvier's vast knowledge of animal structure, to give him a key to the whole skeleton. At about the same time, in the same locality, were found other bones and teeth also, differing from those first discovered, and yet equally unlike those of any living animal. The first evidently belonged to some stout and heavy animal, the others were more slender and of lighter build. From these fragments, ample evidence to him of his results, he drew the outlines of two animals: one which he called the *Palæotherium* (old animal) . . . , and the other *Anoplotherium* (animal without fangs). He presented these figures with an explanatory memoir at the Academy, and announced

them as belonging to some creation preceding the present, since no such animals had ever existed in our own geological period. Such a statement was a revelation to the scientific world; some looked upon it with suspicion and distrust; others, who knew more of comparative anatomy, hailed it as introducing a new era in science; but it was not till complete specimens were actually found of animals corresponding perfectly to those figured and described by Cuvier, proving beyond a doubt their actual existence in ancient times, that all united in wonder and admiration at the result obtained by him with such scanty means.—AGASSIZ *Geological Sketches*, ser. i, ch. 7, p. 185. (H. M. & Co., 1896.)

3486. ———— *Kepler's Laws—His Joy in Proving the Harmony of the Universe.*—It was thus that Kepler viewed this last discovery of his. His fervent disposition was roused to earnest enthusiasm when he had found this law of harmony in the universe. He felt instinctively that he was approaching a yet grander discovery, or that at least he had shown the path by which a greater truth was to be reached and the law of the universe recognized. He might have spoken of himself, had he known what was to come, as the Moses of the astronomy of the future, who saw the promised land afar off, but entered not therein. But he chose rather to use the words of the ancient mystics: "I will rejoice!" he exclaimed; "I will triumph in my sacred fury; for I have found the golden vases of the Egyptians!"*—PROCTOR *Expanse of Heaven*, p. 109. (L. G. & Co., 1897.)

3487. ———— *Result Attained After Long Discouragement—Newton's Discovery of Gravitation Confirmed—Patience and Exactness of Science.*—At the time when Newton attempted to make this comparison between gravity at the surface of the earth and the force which keeps the moon in her orbit, the diameter of the terrestrial globe was not known with sufficient exactness. The result did not completely answer his expectations; he found for the distance which the moon falls towards the earth in one second a little less than the twentieth of an inch (it should be a little more, about 0.053 inch); but altho the difference was not large it appeared sufficient to prevent him from inferring the identity which he hoped to find. The cause of his failure was not explained till sixteen years later. In the year 1682, being present at a meeting of the Royal Society of London, he heard mentioned a new measure of the earth made by the French astronomer Picard, and having obtained the result which that astronomer had found, he again took up the calculation which he had attempted sixteen years previously, employing the new data; but as he proceeded the desired precision came with evidence more and more luminous; the thinker became as if mentally dazed, and felt seized with such emotion that he could not continue, and begged one of his friends to finish the calculation.—FLAMMARION *Popular Astronomy*, bk. ii, ch. 1, p. 92. (A.)

* Referring to the belief of the Pythagoreans that certain sacred secrets were preserved in golden vases shown to Pythagoras by Egyptian priests.

3488. ———— *Terrestrial Substances in the Sun—Revelations of the Spectroscope.*—It has long been supposed that the sun and planets have had a common origin, and that hence the same substances are common to them all. Can we, then, detect the presence of any of our terrestrial substances in the sun? We have learned that the bright bands of a metal are characteristic of the metal; that we can, without seeing the metal, declare its name from the inspection of its bands. The bands are, so to speak, the voice of the metal declaring its presence. Hence, if any of our terrestrial metals be contained in the sun's atmosphere, the dark lines which they produce ought to coincide exactly with the bright lines emitted by the vapor of the metal itself. About sixty bright lines have been determined as belonging to the single metal iron. If the light from the incandescent vapor of iron, obtained by passing electric sparks between two iron wires, be allowed to pass through one-half of a fine slit, and the light of the sun through the other half, the spectra from both sources of light may be placed one underneath the other. When this is done it is found that for every bright line of the iron spectrum there is a dark line of the solar spectrum. Reduced to actual calculation, this means that the chances are more than 1,000,000,000,000,000,000 to 1 that iron is in the atmosphere of the sun. Comparing in the same manner the spectra of other metals, Professor Kirchhoff, to whose genius we owe this splendid generalization, finds iron, calcium, magnesium, sodium, chromium, and many other metals, in the solar atmosphere.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 512. (A., 1900.)

3489. TRIUMPH OF SPIRIT OVER MATTER—*Scott Composing Waverley Novels.*—"John Ballantyne (whom Scott, while suffering under a prolonged and painful illness, employed as his amanuensis) told me that tho Scott often turned himself on his pillow with a groan of torment, he usually continued the sentence in the same breath. But when dialogue of peculiar animation was in progress spirit seemed to triumph altogether over matter; he arose from his couch and walked up and down the room, raising and lowering his voice, and, as it were, acting the parts. It was in this fashion that Scott produced the far greater portion of the 'Bride of Lammermoor,' the whole of the 'Legend of Montrose,' and almost the whole of 'Ivanhoe'" (Lockhart's "Life of Scott," ch. 44).—CARPENTER *Mental Physiology*, bk. i, ch. 3, p. 139. (A., 1900.)

3490. TRIUMPHS OF MECHANICAL SKILL—*Microscopic Lines Ruled on Glass Plate.*—Let not, then, these numbers [the dimensions of light-waves] impair your confidence in our results; but remember that the microscope reveals a universe with dimensions of the same order of magnitude. Moreover, the magnitudes with which we are here dealing are not beyond the limits of mechanical skill. It is possible to rule lines on a plate of glass so close together that the bands of fine lines thus obtained cannot be resolved even by the most powerful microscopes; and I am informed that the German optician Nobert has ruled bands containing about 224,000 lines to the inch. He regularly makes plates with bands consisting of from about 11,000 to 112,000 lines to the inch. These bands are numbered from the 1st to the 19th, and are used for microscopic tests.—COOKE *New Chemistry*, lect. 1, p. 17. (A., 1899.)

3491. TROPICS, PROLIFIC VEGETATION OF—*Numerous Species of Orchids.*—In the tropics the species [of orchids] are very . . . numerous; thus Fritz Müller found in South Brazil more than thirteen kinds belonging to several genera growing on a single cedrela-tree. Mr. Fitzgerald has collected within the radius of one mile of Sydney in Australia no less than sixty-two species, of which fifty-seven were terrestrial. Nevertheless, the number of individuals of the same species is, I believe, in no country nearly so great as that of very many other plants. Lindley formerly estimated that there were in the world about 6,000 species of *Orchideæ*, included in 433 genera. The number of the individuals which come to maturity does not seem to be at all closely determined by the number of seeds which each species produces; and this holds good when closely related forms are compared.—DARWIN *Fertilization of Orchids*, ch. 9, p. 279. (A., 1898.)

3492. TROPICS, PROTECTIVE COLORS IN—*Why Parrots Are Green.*—Passing on to the tropical regions, it is among their evergreen forests alone that we find whole groups of birds whose ground color is green. Parrots are very generally green, and in the east we have an extensive group of green fruit-eating pigeons; while the barbets, bee-eaters, turacous, leaf-thrushes *(Phyllornis)*, white-eyes *(Zosterops)*, and many other groups have so much green in their plumage as to tend greatly to their concealment among the dense foliage. There can be no doubt that these colors have been acquired as a protection, when we see that in all the temperate regions, where the leaves are deciduous, the ground color of the great majority of birds, especially on the upper surface, is a rusty brown of various shades, well corresponding with the bark, withered leaves, ferns, and bare thickets among which they live in autumn and winter, and especially in early spring, when so many of them build their nests.—WALLACE *Darwinism*, ch. 8, p. 131. (Hum.)

3493. TROPICS, RAINFALL IN THE—*Condensation of Vapor by Mountains—Monsoons.*—Warm, southerly winds, blowing over the Bay of Bengal, and becoming laden with vapor during their passage, reach the low level delta of the Ganges and Brahmaputra, where the ordinary heat exceeds that of the sea, and where evaporation is constantly going on from countless marshes and the arms of the great rivers. A mingling of two masses of damp air of different temperatures probably causes the fall of 70 or 80 inches of rain, which takes place on the plains. The monsoon having crossed the delta, impinges on the Khasia Mountains, which rise abruptly from the plain to a mean elevation of between 4,000 and 5,000 feet. Here the wind not only encounters the cold air of the mountains, but, what is far more effective as a refrigerating cause, the aerial current is made to flow upwards, and to ascend to a height of several thousand feet above the sea. Both the air and the vapor contained in it, being thus relieved of much atmospheric pressure, expand suddenly, and are cooled by rarefaction. The vapor is condensed, and about 500 inches of rain are thrown down annually, nearly twenty times as much as falls in Great Britain in a year, and almost all of it poured down in six months. The channel of every torrent and river is swollen at this season, and much sandstone horizontally stratified, and other rocks are reduced to sand and gravel by the flooded streams.—LYELL *Principles of Geology*, bk. ii, ch. 14, p. 200. (A., 1854.)

3494. ——— ——— *Landslides—The Turbid Ganges.*—In another part of India [see 3493], immediately to the westward, similar phenomena are repeated. The same warm and humid winds, copiously charged with aqueous vapor from the Bay of Bengal, hold their course due north for 300 miles across the flat and hot plains of the Ganges, till they encounter the lofty Sikkim Mountains. On the southern flank of these they discharge such a deluge of rain that the rivers in the rainy season rise twelve feet in as many hours. Numerous landslips, some of them extending three or four thousand feet along the face of the mountains, composed of granite, gneiss, and slate, descend into the beds of streams, and dam them up for a time, causing temporary lakes, which soon burst their barriers. "Day and night," says Dr. Hooker, "we heard the crashing of falling trees and the sound of boulders thrown violently against each other in the beds of torrents. By such wear and tear rocky fragments swept down from the hills are in part converted into sand and fine mud; and the turbid Ganges, during its annual inundation, derives more of its

sediment from this source than from the waste of the fine clay of the alluvial plains below.—LYELL *Principles of Geology*, bk. ii, ch. 14, p. 201. (A., 1854.)

3495. TRUSTWORTHINESS OF NATURAL FORCES—*A Belief as Old as Humanity.*—Even the modern idea of law, of the constancy and therefore the trustworthiness of natural forces, has been known, not indeed scientifically but instinctively, to man since first he made a tool and used it as the instrument of purpose. What has science added to this idea, except that the same rule prevails as widely as the universe, and is made subservient in a like manner to knowledge and to will?—ARGYLL *Reign of Law*, ch. 2, p. 69. (Burt.)

3496. TRUTH, ABSOLUTE, UNATTAINABLE BY MAN—Absolute truth no man of science can ever hope to grasp; for he knows that all human search for it must be limited by human capacity.—CARPENTER *Nature and Man*, essay 7, p. 238. (A., 1889.)

3497. TRUTH IN ANCIENT THEORIES—*Hot Springs—Heat of Interior of the Earth.*—The observation made by Arago in 1821, that the deepest Artesian wells are the warmest, threw great light on the origin of thermal springs, and on the establishment of the law that terrestrial heat increases with increasing depth. It is a remarkable fact, which has but recently been noticed, that at the close of the third century St. Patricius, probably Bishop of Pertusa, was led to adopt very correct views regarding the phenomenon of the hot springs at Carthage. On being asked what was the cause of boiling water bursting from the earth, he replied: "Fire is nourished in the clouds and in the interior of the earth, as Etna and other mountains near Naples may teach you. The subterranean waters rise as if through siphons. The cause of hot springs is this: waters which are more remote from the subterranean fire are colder, while those which rise nearer the fire are heated by it and bring with them to the surface which we inhabit an insupportable degree of heat."—HUMBOLDT *Cosmos*, vol. i, p. 223. (H., 1897.)

3498. TRUTH, LIKE NATURE'S GIFTS, TO BE WORKED FOR—Nature never provides for man's wants in any direction, bodily, mental, or spiritual, in such a form as that he can simply accept her gifts automatically. She puts all the mechanical powers at his disposal—but he must make his lever. She gives him corn, but he must grind it. She elaborates coal, but he must dig for it. Corn is perfect, all the products of Nature are perfect, but he has everything to do to them before he can use them. So with truth; it is perfect, infallible. But he cannot use it as it stands. He must work, think, separate, dissolve, absorb, digest; and most of these he must do for himself and within himself.—DRUMMOND *Natural Law in the Spiritual World*, essay 10, p. 326. (H. Al.)

3499. TRUTH LOVED MORE THAN THEORY — *Kepler Abandons Systems that Conflict with Facts.*—What love of the truth as it is in Nature was ever more conspicuous than that which Kepler displayed in his abandonment of each of the ingenious conceptions of the planetary system which his fertile imagination had successively devised, so soon as it proved to be inconsistent with the facts disclosed by observation? In that almost admiring description of the way in which his enemy Mars, "whom he had left at home a despised captive," had "burst all the chains of the equations, and broke forth from the prisons of the tables," who does not recognize the justice of Schiller's definition of the real philosopher, as one who always loves truth better than his system?—CARPENTER *Nature and Man*, essay 6, p. 188. (A., 1889.)

3500. TRUTH, PHYSICIAN DRIVEN TO SEEK—*Responsibility of Life or Death Compels.*—One who, like the physician, has actively to face natural forces which bring about weal or woe is also under the obligation of seeking for a knowledge of the truth, and of the truth only, without considering whether what he finds is pleasant in one way or the other. His aim is one which is firmly settled: for him the success of facts is alone finally decisive. He must endeavor to ascertain beforehand what will be the result of his attack if he pursues this or that course.—HELMHOLTZ *Popular Lectures*, lect. 5, p. 225. (L. G. & Co., 1898.)

3501. TRUTH, SCIENTIFIC, AGREEING WITH POPULAR OBSERVATION—There is another fact of common observation, and now scientifically established: strong scintillations foretell rain. It is the presence of water in greater or less quantity in the atmosphere which exercises the most marked influence on the scintillation, and which modifies its character according to the quantity, either when the water is dissolved in the air, or when it falls to the level of the ground in the liquid state, or in the solid state in the form of snow.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 607. (A.)

3502. TRUTH, SIMPLE, OVERLOOKED — *Transparency Invisible.* — It is probably the very simplicity of the law regarding it [spiritual conformity to type] that has made men stumble; for nothing is so invisible to most men as transparency.—DRUMMOND *Natural Law in the Spiritual World*, essay 8, p. 275. (H. Al.)

3503. TRUTH THE CRITERION OF POETRY— *Tennyson's "Dragon-fly"—Truth to Nature Increases Poetic Charm.*—The criterion of perfect poetry is not elegance, but truth; and that in proportion as the poet's

knowledge of Nature is true, so will his work represent the thoughts which have power to charm, instruct, and better mankind through all time. I know of no better example of the complete reconcilement of poesy and an accurate knowledge of Nature than is contained in Tennyson's "Two Voices." Let any one watch the birth of a dragon-fly, and say whether or not the poet has written sweetly and well—and all the more sweetly because his words are true:

To-day I saw a dragon-fly
Come from the wells where he did lie.

An inner impulse rent the veil
Of his old husk: from head to tail
Came out clear plates of sapphire mail.

He dried his wings: like gauze they grew;
Through crofts and pastures wet with dew
A living flash of light he flew.

—ANDREW WILSON *Science and Poetry*, p. 11. (Hum., 1888.)

3504. TUTELAGE PROLONGED BY CIVILIZATION—*More Time Needed to Prepare for the More Complex Life.*—Now it is owing to the necessity for having a certain number of the more useful routes established before the babe can be trusted from its mother's side that the delay of infancy is required. And even after the child has begun to practise the art of living for itself, time has still to be granted for many purposes—for new route-making, for becoming familiar with established thoroughfares, for practising upon obstacles and ingredients, for learning to perform the journeys quickly and without fatigue, for allowing acts repeated to accelerate and embody themselves as habits. In the savage state, where the after-life is simple, the adjustments are made with comparative ease and speed; but as we rise in the scale of civilization the necessary period of infancy lengthens step by step, until in the case of the most highly educated man, where adjustments must be made to a wide intellectual environment, the age of tutelage extends for almost a quarter of a century.—DRUMMOND *Ascent of Man*, ch. 8, p. 287. (J. P., 1900.)

3505. TWINKLING OF STARS EXPLAINED—*Interference of Light-waves—Iridescence of Striated Surfaces—The Colors of Mother-of-pearl Transferred to Black Sealing-wax.*—By interference in the earth's atmosphere the light of a star, as shown by Arago, is self-extinguished, the twinkling of the star and the changes of color which it undergoes being due to this cause. Looking at such a star through an opera-glass, and shaking the glass so as to cause the image of the star to pass rapidly over the retina, you produce a row of colored beads, the spaces between which correspond to the periods of extinction. Fine scratches drawn upon glass or polished metal reflect the waves of light from their sides; and some, being reflected from opposite sides of the same scratch, interfere with and quench each other. But the obliquity of reflection which extinguishes the shorter waves does not extinguish the longer ones, hence the phenomena of color. These are called the colors of striated surfaces. They are beautifully illustrated by mother-of-pearl. This shell is composed of exceedingly thin layers, which, when cut across by the polishing of the shell, expose their edges and furnish the necessary small and regular grooves. The most conclusive proof that the colors are due to the mechanical state of the surface is to be found in the fact, established by Brewster, that by stamping the shell carefully upon black sealing-wax we transfer the grooves, and produce upon the wax the colors of mother-of-pearl.—TYNDALL *Lectures on Light*, lect. 2, p. 92. (A., 1898.)

3506. TYPE, COMMON, TRACED THROUGH ALL VERTEBRATES—*Legs of Whale and Boa-constrictor.*—The general law to be learned from the series of skeletons in a natural-history museum is that through order after order of fishes, reptiles, birds, beasts, up to man himself, a common type or pattern may be traced, belonging to all animals which are vertebrate—that is, which have a back-bone. Limbs may still be recognized, tho their shape and service have changed, and tho they may even have dwindled into remnants, as if left not for use, but to keep up the old model. Thus, altho a perch's skeleton differs so much from a man's, its pectoral and ventral fins still correspond to arms and legs. Snakes are mostly limbless, yet there are forms which connect them with the quadrupeds, as, for instance, the boa-constrictor's skeleton shows a pair of rudimentary hind legs. The Greenland whale has no visible hind limbs, and its fore limbs are paddles or flippers; yet when dissected, the skeleton shows not only remnants of what in man would be the leg-bones, but the flipper actually has within it the set of bones which belong to the human arm and hand. It is popularly considered that man is especially distinguished from the lower animals by not having a tail; yet the tail is plainly to be seen in the human skeleton, represented by the last tapering vertebræ of the spine.—TYLOR *Anthropology*, ch. 2, p. 36. (A., 1899.)

3507. UNANIMITY, CONVINCING POWER OF—*Astronomy Trusted Because Astronomers Agree.*—In order that this salutary ascendency over opinion should be exercised by the most eminent thinkers it is not necessary that they should be associated and organized. The ascendency will come of itself when the unanimity is attained, without which it is neither desirable nor possible. It is because astronomers agree in their teaching that astronomy is trusted, and not because there is an Academy of Sciences or a Royal Society issuing decrees or passing resolutions.—MILL *Positive Philosophy of Auguste Comte*, p. 91. (H. H. & Co., 1887.)

3508. ——— ——— *Spectrum Analysis Universally Accepted as Trustworthy.*—I do not know any more remarkable fact

in the psychology of belief than the universality with which even the most wonderful —I might say the most romantic—results of spectrum analysis have been accepted as sober truth, not merely by the whole scientific world, but by the general public. And this universality is, I think, to be attributed to these two conditions: first, that the absolute concurrence of scientific men on this subject gives to their statements the value (if I may so express myself) of bank-notes, which any one may convert into the standard gold of personal knowledge merely by inquiring into the matter for himself; and secondly, that these results are additions to our previous knowledge, and do not run counter to any established beliefs.—CARPENTER *Nature and Man*, lect. 7, p. 236. (A., 1889.)

3509. UNCERTAINTY INEVITABLE —*Atmosphere of Venus Makes Exact Observation of Transit Impossible.*—[At the transit of Venus, 1874] an appearance supervened which took most observers by surprise. This was the illumination due to the atmosphere of Venus. Astronomers, it is true, were not ignorant that the planet had, on previous occasions, been seen girdled with a lucid ring; but its power to mar observations by the distorting effect of refraction had scarcely been reckoned with. It proved, however, to be very great. Such was the difficulty of determining the critical instant of internal contact, that (in Colonel Tupman's words) "observers side by side, with adequate optical means, differed as much as twenty or thirty seconds in the times they recorded for phenomena which they have described in almost identical language." —CLERKE *History of Astronomy*, pt. ii, ch. 6, p. 291. (Bl., 1893.)

3510. UNIFICATION OF THE SCIENCES—*Astronomy Needs and Aids All Other Science—The Universe an Intellectually Consistent Whole.*—The unification of the physical sciences is perhaps the greatest intellectual feat of recent times. The process has included astronomy; so that, like Bacon, she may now be said to have "taken all knowledge" (of that kind) "for her province." In return, she proffers potent aid for its increase. Every comet that approaches the sun is the scene of experiments in the electrical illumination of rarefied matter, performed on a huge scale for our benefit. The sun, stars, and nebulæ form so many celestial laboratories, where the nature and mutual relations of the chemical "elements" may be tried by more stringent tests than sublunary conditions afford. The laws of terrestrial magnetism can be completely investigated only with the aid of a concurrent study of the face of the sun. The positions of the planets will perhaps one day tell us something of impending droughts, famines, and cyclones.—CLERKE *History of Astronomy*, int., p. 7. (Bl., 1893.)

3511. UNIFORMITY OF NATURE— *Ancient Sedimentary Deposits Like the Present—Geological Strata Forming Now.*—The great bulk of the derivative rocks being of sedimentary origin, it is obvious that they must have been at the time of their formation spread out in approximately horizontal layers upon the beds of ancient lakes and seas. This we are justified in believing by what we know of the accumulation of similar sediments in our own day. The wide flats of our river-valleys, the broad plains that occupy the sites of silted-up lakes, the extensive deltas of such rivers as the Nile, the Po, the Amazon, the Mississippi, the narrow or wide belts of low-lying land which within a recent period have been gained from the sea, are all made up of various kinds of sediment arranged in gently inclined or approximately horizontal layers. Now, over considerable areas of the earth's surface the derivative rocks show the same horizontal arrangement, a structure which is obviously original.—GEIKIE *Earth Sculpture*, ch. 1, p. 7. (G. P. P., 1898.)

3512. ——— ——— *Ancient Volcanic Action Like the Modern—Fertility and Happiness in the Intervals.*—If we look at the vast masses of volcanic materials erupted in Miocene times in our own island and in Ireland, for example, we might be led to imagine that we have the indications of a veritable "reign of fire," and that the evidence points to a condition of things very different indeed from that which prevails at the present day. But [we must remember] that these volcanic ejections are not the result of one violent effort, but are the product of numerous small outbreaks which have been scattered over enormous periods of time.

When we examine with due care the lavas, tuffs, and other volcanic ejections which constitute such mountain masses as those of the Hebrides, of the Auvergne, and of Hungary, we find clear proofs that the ancient Miocene volcanoes of these districts were clothed with luxuriant forests, through which wild animals roamed in the greatest abundance. The intervals between the ejections of successive lava-streams were often so great that soils were formed on the mountain slope, and streams cut deep ravines and valleys in them.—JUDD *Volcanoes*, ch. 9, p. 278. (A., 1899.)

3513. ——— ——— *A Revelation of the Immutability of God.*—The chemist in his laboratory, as he questions Nature, may be almost said to put her to the torture when, tried in his hottest furnace, or probed by his searching analysis to her innermost arcana, she by a spark or an explosion, or an effervescence, or an evolving substance, makes her distinct replies to his investigations. And . . . in every quarter of the globe her answer is the same—so that, let the experiment, tho a thousand times re-

peated, only be alike in all its circumstances, the result which cometh forth is as rigidly alike, without deficiency, and without deviation. . . . But there is a God who liveth and sitteth there, and these unvarying responses of Nature are all prompted by himself, and are but the utterances of his immutability. They are the replies of a God who never changes, and who hath adapted the whole materialism of creation to the demonstration of it. The certainties of Nature and of science are, in fact, the vocables by which God announces his truth to the world; and when told how impossible it is that Nature can fluctuate, we are only told how impossible it is that the God of Nature can deceive us.—CHALMERS *Astronomical Discourses*, suppl. disc. 1, p. 213. (R. Ct., 1848.)

3514. ——— ——— *Interruption of—Eclipse of the Sun—Perplexity of Animals.*—The effect of the waning light on animals [during an eclipse of the sun at Rio de Janeiro, 1865] was very striking. The Bay of Rio is daily frequented by large numbers of frigate-birds and gannets, which at night fly to the outer islands to roost, while the carrion-crows *(urubús)* swarming in the suburbs, and especially about the slaughter-houses of the city, retire to the mountains in the neighborhood of Tijuca, their line of travel passing over San Christovão. As soon as the light began to diminish, these birds became uneasy; evidently conscious that their day was strangely encroached upon, they were uncertain for a moment how to act. Presently, however, as the darkness increased, they started for their usual night quarters, the water-birds flying southward, the vultures in a northwesterly direction, and they had all left their feeding-grounds before the moment of greatest obscurity arrived. They seemed to fly in all haste, but were not half-way to their night home when the light began to return with rapidly increasing brightness. Their confusion was now at its height. Some continued their flight towards the mountains or the harbor, others hurried back to the city, while others whirled about wholly uncertain what to do next. The reestablishment of the full light of noon seemed to decide them, however, upon making another day of it, and the whole crowd once more moved steadily toward the city.—AGASSIZ *Journey in Brazil*, ch. 2, p. 52. (H. M. & Co., 1896.)

3515. ——— ——— *Maintained amid Contending Forces.*—Battle within battle must be continually recurring with varying success; and yet in the long run the forces are so nicely balanced that the face of Nature remains for long periods of time uniform, tho assuredly the merest trifle would give the victory to one organic being over another.—DARWIN *Origin of Species*, ch. 1, p. 67. (Burt.)

3516. ——— ——— *Natural Laws Unchanged through All Ages—Limitations of the Doctrine.*—The geological record informs us that the general laws of Nature have continued unchanged from the earliest periods to which it relates until the present day. This is the true "uniformitarianism" of geology which holds to the dominion of existing causes from the first. But it does not refuse to admit variations in the intensity of these causes from time to time, and cycles of activity and repose, like those that we see on a small scale in the seasons, the occurrence of storms, or the paroxysms of volcanoes.—DAWSON *Facts and Fancies in Modern Science*, lect. 3, p. 119. (A. B. P. S.)

3517. ——— ——— *Slow Recognition of the Truth.*—Woodward did not hesitate, in 1695, to teach that the entire mass of fossiliferous strata contained in the earth's crust had been deposited in a few months; and, consequently, as their mechanical and derivative origin was already admitted, the reduction of rocky masses into mud, sand, and pebbles, the transportation of the same to a distance, and their accumulation elsewhere in regular strata, were all assumed to have taken place with a rapidity unparalleled in modern times. This doctrine was modified by degrees, in proportion as different classes of organic remains, such as shells, corals, and fossil plants, had been studied with attention. Analogy led every naturalist to assume that each full-grown individual of the animal or vegetable kingdom had required a certain number of months or years for the attainment of maturity, and the perpetuation of its species by generation; and thus the first approach was made to the conception of a common standard of time, without which there are no means whatever of measuring the comparative rate at which any succession of events has taken place at two distinct periods. This standard consisted of the average duration of the lives of individuals of the same genera or families in the animal and vegetable kingdoms; and the multitude of fossils dispersed through successive strata implied the continuance of the same species for many generations. At length the idea that species themselves had had a limited duration arose out of the observed fact that sets of strata of different ages contained fossils of distinct species. Finally, the opinion became general that in the course of ages one assemblage of animals and plants had disappeared after another again and again, and new tribes had started into life to replace them.—LYELL *Principles of Geology*, bk. i, ch. 10, p. 153. (A., 1854.)

3518. UNION, CHEMICAL, VS. MECHANICAL—*A Mixture Differs from a Compound.*—We cannot say that water consists of hydrogen and oxygen in the same sense that bread consists of flour, or sirup of sugar, and mortar of lime. We must be very careful not to transfer our ideas of composition, drawn chiefly from the mixtures we use in common life, directly to chemis-

try. In these mixtures the product partakes, to a greater or less degree, of the character of its constituents, which can be recognized essentially unchanged in the new material, but, in all instances of true chemical union and decomposition, the qualities of the substances concerned in the process entirely disappear, and wholly different substances, with new qualities, appear in their place. —COOKE *New Chemistry*, lect. 5, p. 114. (A., 1899.)

3519. UNION, CLOSE, OF BODY WITH MIND—*Bodily Processes Affected by Sensations.*—Modern physiological psychology emphasizes the wonderfully delicate way in which the whole nervous mass responds to the slightest phases of change in all forms of excitation, with accompanying modifications of even the lowest possible phases of conscious mental life. Haller, for example, noticed that the noise from beating a drum increased the flow of blood from an open vein. Mosso observed that the approach of a lamp toward a patient whose brain was exposed increased the volume of the brain substance. M. Payot claims to have seen the passage of a cloud over the sun increase the respiratory rhythm and pulse-rate of a sleeping infant. M. Féré found that slight sensations of sound and smell sometimes affect a man's dynamometric force. Schiff and Vulpian have observed the pupils of the eyes dilate under the influence of various forms of excitement. Experiments in reaction-time show that increasing the intensity of conscious states of sensation increases the volume of the blood in the forearm and hand with which the agent is reacting.—LADD *Psychology*, ch. 3, p. 48. (S., 1899.)

3520. UNION OF DANGEROUS SUBSTANCES IN SALT—*Combination Harmless and Useful.*—It is a curious fact in Nature that two such substances as chlorin and sodium, both of them so difficult and dangerous to handle, should unite together to form such a useful and harmless compound as common salt. The important element in bleaching-powder is the chlorin which it contains. It is extensively used in the manufacture of paper and in all other materials where bleaching is required. The object of combining it with lime, forming a chlorid of lime, is simply to have a convenient method of holding the chlorin in a safe and convenient manner until it is needed for use.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 26, p. 219. (F. H. & H., 1900.)

3521. UNION OF DISSIMILAR TRAITS—*A Butcher among Song-birds—The Shrike—Hawk's Bill with Sparrow's Foot.*—The marked difference in the temperament of birds is emphasized by finding among the song-birds, who feed on fruit, seeds, and insects, a bird who in his position and choice of food is truly hawklike. Shrikes are solitary, never assembling in flocks or associating with other birds. Their days are days of waiting, varied by a pounce upon some unfortunate field-mouse, or dash into a flock of unsuspecting sparrows. But while they resemble the hawks in these respects, their manner of capturing their prey differs from that of their larger prototypes. The shrike [or butcher-bird] has a hawk's bill, but a sparrow's foot, and, lacking the powerful talons which make so deadly a weapon, he captures his prey with his strong mandibles. Possibly it may be due to his comparatively weak feet that he pursues the singular custom of impaling his prey on some thorn or hanging it from a crotch, where he can better dissect it.—CHAPMAN *Bird-Life*, ch. 7, p. 218. (A., 1900.)

3522. UNION OF LABOR AND ART—Art here [in Italy] stood in close relation with manual labor, and the artist was only distinguished from the manual laborer by higher intellectual gifts.—KAAT *Leonardo da Vinci als Naturforscher.* (Translated for *Scientific Side-Lights.*)

3523. UNION OF RIVERS—*Evils Averted by Nature's Compensation—Speed of Current Increased with Volume.*—A question naturally arises, How the more tranquil rivers of the valleys and plains, flowing on comparatively level ground, can remove the prodigious burden which is discharged into them by their numerous tributaries, and by what means they are enabled to convey the whole mass to the sea? If they had not this removing power their channels would be annually choked up, and the valleys of the lower country and plains at the base of mountain chains would be continually strewed over with fragments of rock and sterile sand. But this evil is prevented by a general law regulating the conduct of running water—that two equal streams do not, when united, occupy a bed of double surface. Nay, the width of the principal river, after the junction of a tributary, sometimes remains the same as before, or is even lessened. The cause of this apparent paradox was long ago explained by the Italian writers, who had studied the confluence of the Po and its feeders in the plains of Lombardy. The addition of a smaller river augments the velocity of the main stream, often in the same proportion as it does the quantity of water. Thus the Venetian branch of the Po swallowed up the Ferranese branch and that of Panaro without any enlargement of its own dimensions. The cause of the greater velocity is, first, that after the union of two rivers the water, in place of the friction of four shores, has only that of two to surmount: secondly, because the main body of the stream being farther distant from the banks, flows on with less interruption; and lastly, because a greater quantity of water, moving more swiftly, digs deeper into the river's bed. By this beautiful adjustment the water which drains the interior country is made continually to occupy less room as it approaches the sea; and thus the most valuable part of our con-

tinents, the rich deltas and great alluvial plains, are prevented from being constantly under water.—LYELL *Principles of Geology,* ch. 14, p. 207. (A., 1854.)

3524. UNION OF WEAKNESS AND STRENGTH—*Plastic Bodies Weak Enough to Yield to an Influence—Strong Enough Not to Yield All at Once.*—Gradual yielding [of plastic bodies] often saves the material from being disintegrated altogether. When the structure has yielded, the same inertia becomes a condition of its comparative permanence in the new form, and of the new habits the body then manifests. Plasticity, then, in the wide sense of the word, means the possession of a structure weak enough to yield to an influence, but strong enough not to yield all at once. Each relatively stable phase of equilibrium in such a structure is marked by what we may call a new set of habits. Organic matter, especially nervous tissue, seems endowed with a very extraordinary degree of plasticity of this sort; so that we may without hesitation lay down as our first proposition the following, that the phenomena of habit in living beings are due to the plasticity of the organic materials of which their bodies are composed.—JAMES *Psychology,* vol. i, ch. 4, p. 104. (H. H. & Co., 1899.)

3525. UNITY AMID DIVERSITY—*Disease Reveals Correlation of Parts of an Organism.*—The truth is that all the parts of an organism are bound together as one whole by a pervading system of correlations as intricate as they are obscure. When the organism is in health, and all its parts are working in harmony, the wonder of these correlations is not perceived. But they are brought out in a marked degree by the phenomena of disease, and also by the phenomena of monstrosity or malformation. The "sympathy" which the most distant and apparently unconnected parts of an organism show with each other, when one of them is affected by disease, is the index of correlations whose nature is utterly beyond the reach of our anatomy.—ARGYLL *Reign of Law,* ch. 5, p. 147. (Burt.)

3526. ——— ——— *Physics and Metaphysics Complementary, Not Antagonistic.*—Thus we arrive at the singular result that, of the two paths opened up to us in the "Discourse upon Method," the one leads, by way of Berkeley and Hume, to Kant and idealism; while the other leads, by way of De la Mettrie and Priestley, to modern physiology and materialism. Our stem divides into two main branches, which grow in opposite ways, and bear flowers which look as different as they can well be. But each branch is sound and healthy, and has as much life and vigor as the other. If a botanist found this state of things in a new plant, I imagine that he might be inclined to think that his tree was monœcious—that the flowers were of different sexes, and that, so far from setting up a barrier between the two branches of the tree, the only hope of fertility lay in bringing them together. I may be taking too much of a naturalist's view of the case, but I must confess that this is exactly my notion of what is to be done with metaphysics and physics. Their differences are complementary, not antagonistic; and thought will never be completely fruitful until the one unites with the other.—HUXLEY *Lay Sermons,* serm. 14, p. 337. (G. P. P., 1899.)

3527. ——— ——— *Uniform Motion of Planets and Satellites—One Common Impulse Affecting All.*—All the planets travel the same way round. This is true not only of the eight primary planets, but of the asteroids, now more than a hundred and thirty in number. Again, all the secondary planets or satellites travel the same way round (this direction of revolution being the same as that in which the planets revolve round the sun)—except the satellites of Uranus, which, however, can hardly be said to have any direction of motion with reference to the general level in which the planetary system circuits, for they travel in planes nearly square to that level. Lastly, as respects direction of motion, all the planets whose rotation has been observed, including our earth and the moon, and the sun also, rotate on their axes in the same direction. It must be understood that this direction is one and the same for all these motions—the revolutions of the planets around the sun, of the satellites round the planets, and of the planets on their axes. It seems natural to infer that the uniformity is the result of some general condition affecting the whole scheme from the beginning.—PROCTOR *Expanse of Heaven,* p. 179. (L. G. & Co., 1897.)

3528. ——— ——— *Various Adjustments Accomplish a Single End—Insects Compelled to Fertilize Orchids.*—Thus the use of all the parts of the flower (namely, the inflected edges, or the polished inner sides of the labellum—the two orifices and their position close to the anthers and stigma—the large size of the medial rudimentary stamen) are rendered intelligible. An insect which enters the labellum is thus compelled to crawl out by one of the two narrow passages, on the sides of which the pollen masses and stigma are placed. We have seen that exactly the same end is gained in the case of *Coryanthes* by the labellum being half filled with secreted fluid; and in the case of *Pterostylis* and some other Australian orchids by the labellum being irritable, so that when touched by an entering insect it shuts up the flower, with the exception of a single narrow passage.—DARWIN *Fertilization of Orchids,* ch. 8, p. 231. (A., 1898.)

3529. "UNITY" BECOMES A SNARE—*Systematizing Overdone—Perfection by Diversity.*—The *fons errorum* in M.

Comte's later speculations is this inordinate demand for "unity" and "systematization." This is the reason why it does not suffice to him that all should be ready, in case of need, to postpone their personal interests and inclinations to the requirements of the general good; he demands that each should regard as vicious any care at all for his personal interests, except as a means to the good of others—should be ashamed of it, should strive to cure himself of it, because his existence is not "systematized," is not in "complete unity," as long as he cares for more than one thing. The strangest part of the matter is that this doctrine seems to M. Comte to be axiomatic. That all perfection consists in unity, he apparently considers to be a maxim which no sane man thinks of questioning. It never seems to enter into his conceptions that any one could object *ab initio*, and ask why this universal systematizing, systematizing, systematizing? Why is it necessary that all human life should point but to one object, and be cultivated into a system of means to a single end? May it not be the fact that mankind, who, after all, are made up of single human beings, obtain a greater sum of happiness when each pursues his own, under the rules and conditions required by the good of the rest, than when each makes the good of the rest his only object, and allows himself no personal pleasures not indispensable to the preservation of his faculties? The regimen of a blockaded town should be cheerfully submitted to when high purposes require it, but is it the ideal perfection of human existence?—MILL *Positive Philosophy of Auguste Comte*, p. 127. (H. H. & Co., 1887.)

3530. UNITY, LOWER VS. HIGHER —*Position of Agnosticism.*—[The] fundamental inconsistency in the agnostic philosophy becomes all the more remarkable when we find that the very men who tell us that we are not one with anything above us are the same who insist that we are one with everything beneath us. Whatever there is in us or about us which is purely animal we may see everywhere; but whatever there is in us purely intellectual and moral we delude ourselves if we think we see it anywhere. There are abundant homologies between our bodies and the bodies of the beasts, but there are no homologies between our minds and any mind which lives and manifests itself in Nature. Our livers and our lungs, our vertebræ and our nervous systems, are identical in origin and in function with those of the living creatures round us: but there is nothing in Nature or above it which corresponds to our forethought, or design, or purpose—to our love of the good or our admiration of the beautiful—to our indignation with the wicked, or to our pity for the suffering and the fallen. I venture to think that no system of philosophy that has ever been taught on earth lies under such a weight of antecedent improbability; and this improbability increases in direct proportion to the success of science in tracing the unity of Nature, and in showing step by step how its laws and their results can be brought more and more into direct relation with the mind and intellect of man.—ARGYLL *Unity of Nature*, ch. 8, p. 166. (Burt.)

3531. UNITY OF ALL KNOWLEDGE —The truth is that there is no branch of human inquiry, however purely physical, which is more than the word "branch" implies; none which is not connected through endless ramifications with every other, and especially that which is the root and center of them all. If He who formed the mind be one with Him who is the Orderer of all things concerning which that mind is occupied, there can be no end to the points of contact between our different conceptions of them, of Him, and of ourselves.—ARGYLL *Reign of Law*, ch. 2, p. 35. (Burt.)

3532. UNITY OF LANGUAGE WRONGLY INFERRED—*History Told in Borrowed Words—Intercourse of Nations.*—Before now a writer has proved to his own satisfaction that Turkish, Arabic, and Persian are all branches of one primitive language, his argument being that the Turks call a man *adam*, as the Arabs call the first man, and a father *pader*, which is like the Persian word. The fact is true enough, but what the argument omits to notice is that the Turks have been for ages enriching their own barbaric language by taking words from the cultured Arabic and Persian, and *adam* and *pader* are such lately borrowed words, not philologically Turkish at all. Borrowed words like these are indeed valuable evidence, but what they prove is not the common origin of languages—it is intercourse between the nations speaking them. They often give the clew to the country from which some new produce was obtained, or some new instrument, or idea, or institution was learned. Thus in English it is seen by the very words how Italy furnished us with *opera*, *sonata*, *chiaroscuro*, while Spain gave *gallina* and *mulatto*; how from the Hebrews we have *sabbath* and *jubilee*, from the Arabs *zero* and *magazine*, while Mexico has supplied *chocolate* and *tomato*, Haiti *hammock* and *hurricane*, Peru *guano* and *quinin*, and even the languages of the South Sea Islands are represented by *taboo* and *tatoo*. But in all this there is not one particle of evidence that any one of these languages is sprung from the same family with any other.—TYLOR *Anthropology*, ch. 6, p. 154. (A., 1899.)

3533. UNITY OF MAN WITH LOWER NATURE—*A Beneficent Provision.*—It is because of the composition of our body that the animals and plants around us are capable of ministering to our support—that the common air is to us the very

breath of life, and that herbs and minerals in abundance have either poisoning properties or healing virtue.—ARGYLL *Unity of Nature*, ch. 2, p. 28. (Burt.)

3534. UNITY OF MANKIND—*Likeness, Mental and Bodily, of All Human Races.*—Now if, as some have thought, the negroes, Mongolians, whites, and other races were distinct species, each sprung from a separate origin in its own region, then the peopling of the globe might require only a moderate time, the races having only to spread each from its own birthplace. But the opinion of modern zoologists, whose study of the species and breeds of animals makes them the best judges, is against this view of several origins of man, for two principal reasons. First, that all tribes of men, from the blackest to the whitest, the most savage to the most cultured, have such general likeness in the structure of their bodies and the working of their minds as is easiest and best accounted for by their being descended from a common ancestry, however distant. Second, that all the human races, notwithstanding their form and color, appear capable of freely intermarrying and forming crossed races of every combination, such as the millions of mulattos and mestizos sprung in the New World from the mixture of Europeans, Africans, and native Americans; this again points to a common ancestry of all the races of man. We may accept the theory of the unity of mankind as best agreeing with ordinary experience and scientific research.—TYLOR *Anthropology*, ch. 1, p. 5. (A., 1899.)

3535. ——— ——— *Proof that Variety Is Consistent with Common Origin—Man's Command of the Whole Habitable Globe.*—I may refer the reader to the writings of Blumenbach, Prichard, Lawrence, and more recently Latham for convincing proofs that the varieties of form, color, and organization of different races of men are perfectly consistent with the generally received opinion that all the individuals of the species have originated from a single pair; and, while they exhibit in man as many diversities of a physiological nature as appear in any other species, they confirm also the opinion of the slight deviation from a common standard of which species are capable.

The power of existing and multiplying in every latitude, and in every variety of situation and climate, which has enabled the great human family to extend itself over the habitable globe, is partly, says Lawrence, the result of physical constitution, and partly of the mental prerogative of man. If he did not possess the most enduring and flexible corporeal frame, his arts would not enable him to be the inhabitant of all climates, and to brave the extremes of heat and cold and the other destructive influences of local situation. Yet, notwithstanding this flexibility of bodily frame, we find no signs of indefinite departure from a common standard, and the intermarriages of individuals of the most remote varieties are not less fruitful than between those of the same tribe.—LYELL *Principles of Geology*, bk. iii, ch. 36, p. 609. (A., 1854.)

3536. ——— ——— *The Crossing of Dissimilar Races.*—It may be strongly argued . . . that not only do the bodily and mental varieties of mankind blend gradually into one another, but that even the most dissimilar races can intermarry in all directions, producing mixed or sub-races which, when left to themselves, continue their own kind. Advocates of the polygenist theory, that there are several distinct races of man, sprung from independent origins, have denied that certain races, such as the English and native Australians, produce fertile half-breeds. But the evidence tends more and more to establish crossing as possible between all races, which goes to prove that all the varieties of mankind are zoologically of one species.—TYLOR *Anthropology*, ch. 3, p. 85. (A., 1899.)

3537. UNITY OF NATURE—[The] substitution or repetition of similar and almost identical forms, in regions that are separated from each other by seas or wide intervening tracts, is a wonderful law of Nature. It prevails even in the rarest forms of the floras.—HUMBOLDT *Views of Nature*, p. 317. (Bell, 1896.)

3538. ——— ——— *A Mental Conception—Theory of Development the Perception of a Plan.*—All theories of development have been simply attempts to suggest the manner in which or the physical process by means of which this ideal continuity of type and pattern has been preserved. But whilst all these suggestions have been in the highest degree uncertain, some of them violently absurd, the one thing which is certain is the fact for which they endeavor to account. And what is that fact? It is one which belongs to the world of mind, not to the world of matter. When Professor Owen tells us, for example, that certain jointed bones in the whale's paddle are the same bones which in the mole enable it to burrow, which in the bat enable it to fly, and in man constitute his hand, with all its wealth of functions, he does not mean that physically and actually they are the same bones, nor that they have the same uses, nor that they ever have been or ever can be transferable from one kind of animal to another. He means that in a purely ideal or mental conception of the plan of all vertebrate skeletons these bones occupy the same relative place—relative, that is, not to origin or use, but to the plan or conception of that skeleton as a whole.—ARGYLL *Reign of Law*, ch. 1, p. 19. (Burt.)

3539. ——— ——— *Apprehended by Savage—Recognition of One Great, Unseen Power.*—We find even among the most savage nations (as my own travels enable me

to attest) a certain vague, terror-stricken sense of the all-powerful unity of natural forces, and of the existence of an invisible, spiritual essence manifested in these forces, whether in unfolding the flower and maturing the fruit of the nutrient tree, in upheaving the soil of the forest, or in rending the clouds with the might of the storm. We may here trace the revelation of a bond of union, linking together the visible world and that higher spiritual world which escapes the grasp of the senses.—HUMBOLDT *Cosmos*, vol. i, int., p. 36. (H., 1897.)

3540. ——— ——— *Evaporation of Solids, as Ice and Metals.*—Metals, and probably all solids, evaporate at ordinary temperatures. It has long been known that ice evaporates very rapidly, and now it is found that metals do the same, and the evaporation can be detected at temperatures far below their melting-points. All these curious phenomena give us new ideas as to the constitution of matter, and lead us to the conclusion that the extreme mobility of the molecules of gases has its analogue in liquids and even in solids. The flow of metals, their diffusion into other metals, and their evaporation, lead to the conclusion that a proportion of their molecules must possess considerable mobility, and when these reach the surface they are enabled to escape either into other bodies in contact with them or into the atmosphere. This proportion of rapidly moving molecules gives to solids some of the characteristics of liquids and of gases.—WALLACE *The Wonderful Century*, ch. 7, p. 57. (D. M. & Co., 1899.)

3541. ——— ——— *Familiar Birds or Flowers in Strange Lands—Arctic Lichen under Shadow of Palm.*—In all regions, however far away from his own home, in the midst of a fauna and flora entirely new to him, the traveler is startled occasionally by the song of a bird or the sight of a flower so familiar that it transports him at once to woods where every tree is like a friend to him. It seems as if something akin to what in our own mental experience we call reminiscence or association existed in the workings of Nature; for tho the organic combinations are so distinct in different climates and countries, they never wholly exclude each other. Every zoological and botanical province retains some link which binds it to all the rest, and makes it part of the general harmony. The arctic lichen is found growing under the shadow of the palm on the rocks of the tropical sierra, and the song of the thrush and the tap of the woodpecker mingle with the sharp, discordant cries of the parrot and paroquet.—AGASSIZ *Geological Sketches*, ser. ii, p. 188. (H. M. & Co., 1896.)

3542. ——— ——— *Is Man an Exception?*—We have only to observe, in the first place, the strange and anomalous position in which it [*i. e.*, the assumption that in the system of Nature, as thus seen and known, there are no phenomena due to mind having any analogies with our own] places man. As regards at least the higher faculties of his mind, he is allowed no place in Nature, and no fellowship with any other thing or any other being outside of Nature. He is absolutely alone—out of all relation with the universe around him, and under a complete delusion when he sees in any part of it any mental homologies with his own intelligence, or with his own will, or with his own affections. Does this absolute solitariness of position as regards the higher attributes of man—does it sound reasonable, or possible, or consistent with some of the most fundamental conceptions of science? How, for example, does it accord with that great conception whose truth and sweep become every day more apparent—the unity of Nature?—ARGYLL *Unity of Nature*, ch. 8, p. 165. (Burt.)

3543. ——— ——— *Magnetism Apparently Universal as Gravitation.*—This process of unification of the cosmos . . . was carried no further until the fact unexpectedly emerged from a vast and complicated mass of observations, that the magnetism of the earth is subject to subtle influences, emanating, certainly, from some, and presumably . . . from all of the heavenly bodies; the inference being thus rendered at least plausible that a force not less universal than gravity itself, but with whose modes of operation we are as yet unacquainted, pervades the universe, and forms, it might be said, an intangible bond of sympathy between its parts. Now for the investigation of this influence two roads are open. It may be pursued by observation either of the bodies from which it emanates, or of the effects which it produces—that is to say, either by the astronomer or by the physicist, or, better still, by both concurrently. Their acquisitions are mutually profitable: nor can either be considered as independent of the other. Any important accession to knowledge respecting the sun, for example, may be expected to cast a reflected light on the still obscure subject of terrestrial magnetism: while discoveries in magnetism or its *alter ego* electricity must profoundly affect solar inquiries.—CLERKE *History of Astronomy*, pt. ii, ch. 1, p. 175. (Bl., 1893.)

3544. ——— ——— *Microscopic Revelations of Minutest Cell Join with Telescopic Study of Sun and Stars.*—To the scientific worker no subject is too vast for his research, no object so minute as to be unworthy of his most patient study. In some . . . inquiries concerning the nature of volcanic action we shall be led to an investigation of the phenomena displayed in the sun, moon, comets, and other great bodies of the universe; but another road to truths of the same grandeur and importance is found . . . in an examination of the

mode of development of crystallites, and a study of the materials contained in the microscopic cavities of the minutest crystals. —JUDD *Volcanoes*, ch. 3, p. 66. (A., 1899.)

3545. ——— ——— *One Plan in Structure of Diverse Animals—Leg and Jaw of Young Lobster Indistinguishable.*—[The] study of development proves that the doctrine of unity of plan is not merely a fancy, that it is not merely one way of looking at the matter, but that it is the expression of deep-seated, natural facts. The legs and jaws of the lobster may not merely be regarded as modifications of a common type—in fact and in Nature they are so—the leg and the jaw of the young animal being at first indistinguishable. — HUXLEY *Lay Sermons*, serm. 6, p. 101. (A., 1895.)

3546. ——— ——— *The Conservation of Energy—All Forces May Be One.*—It may be that all natural forces are resolvable into some one force; and indeed in the modern doctrine of the correlation of forces an idea which is a near approach to this has already entered the domain of science. It may also be that this one force, into which all others return again, is itself but a mode of action of the divine will. But we have no instruments whereby to reach this last analysis.—ARGYLL *Reign of Law*, ch. 3, p. 76. (Burt.)

3547. ——— ——— *The Kosmos.*—The system of Nature in which we live impresses itself on the mind as one system. It is under this impression that we speak of it as the "universe." It was under the same impression, but with a conception specially vivid of its order and its beauty, that the Greeks called it the "kosmos." By such words as these we mean that Nature is one whole—a whole of which all the parts are inseparably united—joined together by the most curious and intimate relations, which it is the highest work of observation to trace, and of reason to understand.—ARGYLL *Unity of Nature*, ch. 1, p. 1. (Burt.)

3548. ——— ——— *The One Great Lesson of Modern Science.*—What is the philosophic purport of these beautiful and sublime discoveries with which the keen insight and patient diligence of modern students of science are beginning to be rewarded? What is the lesson that is taught alike by the correlation of forces, by spectrum analysis, by the revelations of chemistry as to the subtle behavior of molecules inaccessible to the eye of sense, by the astronomy that is beginning to sketch the physical history of countless suns in the firmament, by the paleontology which is slowly unraveling the wonders of past life upon the earth through millions of ages? What is the grand lesson that is taught by all this? It is the lesson of the unity of Nature. To learn it rightly is to learn that all the things that we can see and know in the course of our life in this world are so intimately woven together that nothing could be left out without reducing the whole marvelous scheme to chaos.—FISKE *Through Nature to God*, pt. i, ch. 4, p. 23. (H. M. & Co., 1900.)

3549. UNITY OF ORIGIN OF EACH ORGANISM—*Distribution from a Single Center.*—The most important principle from which we must start in chorology, and of the truth of which we are convinced by due examination of the theory of selection, is that, as a rule, every animal and vegetable species has arisen only once in the course of time and only in one place on the earth —its so-called "center of creation"—by natural selection. I share this opinion of Darwin's unconditionally, in respect to the great majority of higher and perfect organisms, and in respect to most animals and plants in which the division of labor, or differentiation of the cells and organs of which they are composed, has attained a certain stage. For it is quite incredible, or could at best only be an exceedingly rare accident, that all the manifold and complicated circumstances—all the different conditions of the struggle for life which influence the origin of a new species by natural selection—should have worked together in exactly the same agreement and combination more than once in the earth's history, or should have been active at the same time at several different points of the earth's surface.—HAECKEL *History of Creation*, vol. i, ch. 14, p. 166. (K. P. & Co., 1899.)

3550. UNITY OF PERFECTION AND HAPPINESS—*Pleasure and Pain—Delight of Abundant Spontaneous Activity.*—Human perfection and human happiness coincide, and thus constitute, in reality, but a single end. For as, on the one hand, the perfection or full development of a power is in proportion to its capacity of free, vigorous, and continued action, so, on the other, all pleasure is the concomitant of activity; its degree being in proportion as that activity is spontaneously intense, its prolongation in proportion as that activity is spontaneously continued; whereas, pain arises either from a faculty being restrained in its spontaneous tendency to action, or from being urged to a degree, or to a continuance of energy beyond the limit to which it of itself freely tends. To promote our perfection is thus to promote our happiness; for to cultivate fully and harmoniously our various faculties is simply to enable them by exercise to energize longer and stronger without painful effort—that is, to afford us a larger amount of a higher quality of enjoyment.—HAMILTON *Metaphysics*, lect. 2, p. 15. (G. & L., 1859.)

3551. UNITY OF TENDENCY OF CERTAIN EPOCHS—*The Fifteenth Century in Discovery.*—The fifteenth century belongs to those remarkable epochs in which all the efforts of the mind indicate one determined

and general character, and one unchanging striving toward the same goal. The unity of this tendency, and the results by which it was crowned, combined with the activity of whole races, give to the age of Columbus, Sebastian Cabot, and Gama, a character both of grandeur and enduring splendor. In the midst of two different stages of human culture the fifteenth century may be regarded as a period of transition which belongs both to the Middle Ages and to the beginning of more recent times. It is the age of the greatest discoveries in space, embracing almost all degrees of latitude and all elevations of the earth's surface. While this period doubled the number of the works of creation known to the inhabitants of Europe, it likewise offered to the intellect new and powerful incitements toward the improvement of natural sciences, in the departments of physics and mathematics.—HUMBOLDT *Cosmos*, vol. ii, pt. ii, p. 228. (H., 1897.)

3552. UNITY OF THE SCIENCES—*Perhaps All Elements One—Alchemist's Dream May Come True.*—Every important discovery establishes a closer kinship between the sciences. The time has already come when to know any one of the sciences thoroughly it is necessary to know the rest: in fact, all the so-called natural sciences are different branches of one great science. It is doubtless true that there is but one energy, and it may be that there is but one element of matter out of which all the various so-called elements come.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 20, p. 170. (F. H. & H., 1900.)

3553. UNITY OF THE UNIVERSE—It is every day becoming more and more clear that our earth is bound by ties of the closest resemblance to the other members of that family of worlds to which it belongs, and that the materials entering into their constitution and the forces operating in all are the same. . . . There are the strongest grounds for believing the interior of our globe to consist of similar materials to those found in the small planetary bodies known as meteorites. That the comets are merely aggregations of such meteorites, and that the planets differ from them only in their greater dimensions, may be regarded as among the demonstrated conclusions of the astronomer. The materials found most abundantly in meteorites and in the interior of our globe are precisely the same as those which are proved to exist in an incandescent state in our sun. Hence we are led to conclude that the whole of the bodies of the solar system are composed of the same chemical elements.—JUDD *Volcanoes*, ch. 12, p. 360. (A., 1899.)

3554. ——— ——— *Continuity of the Law of Gravitation through All Worlds.*—The most striking examples of the continuousness of law are, perhaps, those furnished by astronomy, especially in connection with the more recent applications of spectrum analysis. But even in the case of the simpler laws the demonstration is complete. There is no reason apart from continuity to expect that gravitation, for instance, should prevail outside our world. But wherever matter has been detected throughout the entire universe, whether in the form of star or planet, comet or meteorite, it is found to obey that law. "If there were no other indication of unity than this it would be almost enough. For the unity which is implied in the mechanism of the heavens is indeed a unity which is all-embracing and complete. The structure of our own bodies, with all that depends upon it, is a structure governed by and therefore adapted to the same force of gravitation which has determined the form and the movements of myriads of worlds. Every part of the human organism is fitted to conditions which would all be destroyed in a moment if the forces of gravitation were to change or fail.—DRUMMOND *Natural Law in the Spiritual World*, p. 36. (H. Al.)

3555. ——— ——— *Earthly Elements Found in Far-off Stars—Aldebaran.*—The light of this star [Aldebaran] is of a pale red. Seen in the spectroscope it presents at a glance a great number of strong lines, particularly in the orange, green, and blue. The positions of about seventy of these lines have been measured, and coincidences have been found with the spectra of *sodium, magnesium, hydrogen, calcium, iron, bismuth, tellurium, antimony,* and *mercury.* Seven other elements have been compared with this star, namely—*nitrogen, cobalt, tin, lead, cadmium, lithium,* and *barium;* but no coincidence has been observed.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 608. (A.)

3556. ——— ——— *Gravitation Holds through Boundless Space.*—In the front rank of all . . . is the law of gravitation. The celestial bodies, as you all know, float and move in infinite space. Compared with the enormous distances between them, each of us is but as a grain of dust. The nearest fixed stars, viewed even under the most powerful magnification, have no visible diameter: and we may be sure that even our sun, looked at from the nearest fixed stars, would only appear as a single luminous point, seeing that the masses of those stars, in so far as they have been determined, have not been found to be materially different from that of the sun. But, notwithstanding these enormous distances, there is an invisible tie between them which connects them together, and brings them in mutual interdependence. This is the force of gravitation with which all heavy masses attract each other. We know this force as gravity when it is operative between an earthly body and the mass of our earth. The force which causes a body to fall to the ground is none other than that which continually

compels the moon to accompany the earth in its path round the sun, and which keeps the earth itself from fleeing off into space, away from the sun.—HELMHOLTZ *Popular Lectures,* lect. 4, p. 145. (L. G. & Co., 1898.)

3557. ——— ——— *Laws of Gravitation and of Chemistry the Same through Farthest Space.*—That a science of stellar chemistry should not only have become possible, but should already have made material advances, is assuredly one of the most amazing features in the swift progress of knowledge our age has witnessed. Custom can never blunt the wonder with which we must regard the achievement of compelling rays emanating from a source devoid of sensible magnitude through immeasurable distance, to reveal, by its peculiarities, the composition of that source. The discovery of revolving double stars assured us that the great governing force of the planetary movements, and of our own physical existence, sways equally the courses of the farthest suns in space; the application of prismatic analysis certified to the presence in the stars of the familiar materials, no less of the earth we tread, than of the human bodies built up out of its dust and circumambient vapors.—CLERKE *History of Astronomy,* pt. ii, ch. 12, p. 450. (Bl., 1893.)

3558. ——— ——— *Sodium Found in Spectrum of a Comet.*—Comet Wells [in its circuit], approached its [the sun's] surface within little more than five million miles on June 10, 1882; and it is not doubtful that to this circumstance the novel feature in its incandescence was due. During the first half of April its spectrum was of the normal type, tho the carbon bands were unusually weak; but with increasing vicinity to the sun they died out, and the entire light seemed to become concentrated into a narrow, unbroken, brilliant streak, hardly to be distinguished from the spectrum of a star. This unusual behavior excited attention, and a strict watch was kept. It was rewarded at the Dunecht Observatory, May 27, by the discernment of what had never before been seen in a comet—the yellow ray of sodium. By June 1 this had kindled into a blaze overpowering all other emissions. The light of the comet was practically monochromatic; and the image of the entire head, with the root of the tail, could be observed, like a solar prominence, depicted, in its new saffron vesture of vivid illumination, within the jaws of an open slit.—CLERKE *History of Astronomy,* pt. ii, ch. 11, p. 431. (Bl., 1893.)

3559. UNITY, VISIBLE AND TANGIBLE—*Luminiferous Ether a Solid—The Crystalline Orb of Poetry.*—Sir J. Herschel has declared that the luminiferous ether must be conceived of not as an air, nor as a fluid, but rather as a solid—"in this sense, at least, that its particles cannot be supposed as capable of interchanging places, or of bodily transfer to any measurable distance from their own special and assigned localities in the universe." Well may Sir J. Herschel add that "this will go far to realize (in however unexpected a form) the ancient idea of a crystalline orb." And thus the wonderful result of all investigation is that this earth is in actual rigid contact with the most distant worlds in space—in rigid contact, that is to say, through a medium which touches and envelops all, and which is incessantly communicating from one world to another the minutest vibrations it receives.—ARGYLL *Unity of Nature,* ch. 1, p. 8. (Burt.)

3560. UNIVERSALITY OF DEEP-SEA LIFE—*No Part of the Ocean Azoic.*—As soon as it became clear to naturalists that there is no part of the ocean, however deep it may be, that deserves the name "azoic," but that almost every part has a fauna of greater or less density, the problem of the origin of this fauna presented itself.—HICKSON *Fauna of the Deep Sea,* ch. 3, p. 53. (A., 1894.)

3561. UNIVERSALITY OF EMULATION—*Affects Even Religion (2 Cor. ix, 2-4).*—Emulation or rivalry, a very intense instinct, [is] especially rife with young children, or at least especially undisguised. Every one knows it. Nine-tenths of the work of the world is done by it. We know that if we do not do the task some one else will do it and get the credit; so we do it. It has very little connection with sympathy, but rather more with pugnacity.—JAMES *Psychology,* vol. ii, ch. 24, p. 409. (H. H. & Co., 1899.)

3562. UNIVERSE, ANCIENT IDEA OF THE—*Cicero's Scheme as Given in the "Dream of Scipio"—Hearing Blunted by Harmony.*—The universe is composed of nine circles, or rather of nine globes, which move. The external sphere is that of the sky, which includes all the others, and on which are fixed the stars. Within revolve seven globes, drawn along by a motion contrary to that of the sky. On the first circle revolves the star which men call Saturn; on the second moves Jupiter, a star beneficent and propitious to human beings; then comes Mars, glowing and abhorred; below, occupying the middle region, shines the sun, chief, prince, moderator of the other stars, life of the world, whose immense globe illuminates and fills the volume of its light. After him come, like two companions, Venus and Mercury. Finally, the lower orbit is occupied by the moon, which borrows its light from the day-star. Below this last celestial circle there is nothing but mortal and corruptible, with the exception of the souls given by divine kindness to the human race. Above the moon all is eternal. Our earth, placed at the center of the world, and separated from the sky in all directions, remains motionless, and all heavy bodies are drawn towards it by their own weight.

Formed of unequal intervals, but combined according to a correct proportion, harmony results from the motion of the sphere, which, forming grave and high tones in a common accord, makes with all these varied notes a melodious concert. Such grand motions cannot be accomplished in silence, and Nature has placed a grave tone at the slow and inferior orbit of the moon, and a high tone at the superior and rapid orbit of the starry firmament; with these two limits of the octave, the eight moving globes produce seven tones in different ways, and this number is the bond of all things in general. The ears of men filled with this harmony know not how to hear it, and mortals do not possess a more imperfect sense. It is thus that the tribes near the Cataracts of the Nile have lost the power of hearing them. The splendid concert of the whole universe in its rapid revolution is so prodigious that your ears are closed to this harmony, as your glances sink before the fires of the sun, whose piercing light dazzles and blinds you.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 1, p. 332. (A.)

3563. UNIVERSE DIVIDED DIFFERENTLY BY EACH INDIVIDUAL— *"Me" and "Not-me."*—There is . . . one entirely extraordinary case in which no two men ever are known to choose alike. One great splitting of the whole universe into two halves is made by each of us; and for each of us almost all of the interest attaches to one of the halves; but we all draw the line of division between them in a different place. When I say that we all call the two halves by the same names, and that those names are "me" and "not-me" respectively, it will at once be seen what I mean. The altogether unique kind of interest which each human mind feels in those parts of creation which it can call me or mine may be a moral riddle, but it is a fundamental psychological fact. No mind can take the same interest in his neighbor's me as in his own. . . . Each of us dichotomizes the cosmos in a different place.—JAMES *Psychology*, vol. i, ch. 9, p. 289. (H. H. & Co., 1899.)

3564. UNIVERSE EVANESCENT— *Its Energy at Last Expended—Science Has No Prophecy Beyond—"They All Shall Grow Old as a Garment, and as a Vesture Shalt Thou Change Them, and They Shall Be Changed" (Ps. cii, 26).*—We are dependent upon the sun and center of our system, not only for the mere energy of our frames, but also for our delicacy of construction—the future of our race depends upon the sun's future. But we have seen that the sun must have had a beginning, and that he will have an end. We are thus induced to generalize still further, and regard, not only our own system, but the whole material universe, when viewed with respect to serviceable energy, as essentially evanescent, and as embracing a succession of physical events which cannot go on forever as they are. But here at length we come to matters beyond our grasp; for physical science cannot inform us what must have been before the beginning, nor yet can it tell us what will take place after the end.—STEWART *Conservation of Energy*, ch. 6, p. 414. (Hum., 1880.)

3565. UNIVERSE, MECHANICAL THEORY OF THE— *Laplace's Nebular Hypothesis—Change of View from Eighteenth to Nineteenth Century.*—[Laplace's] scheme of cosmical evolution was a characteristic bequest of the eighteenth century to the nineteenth. It possessed the self-sufficing symmetry and entireness appropriate to the ideas of a time of renovation, when the complexity of Nature was little accounted of in comparison with the imperious orderliness of the thoughts of man. Since it was propounded, however, knowledge has transgressed many boundaries, and set at naught much ingenious theorizing. How has it fared with Laplace's sketch of the origin of the world? It has at least not been discarded as effete. The groundwork of speculation on the subject is still furnished by it. It is, nevertheless, admittedly inadequate. Of much that exists it gives no account, or an erroneous one. The march of events certainly did not everywhere—even if it did anywhere—follow the exact path prescribed for it. Yet modern science attempts to supplement, but scarcely ventures to supersede it.—CLERKE *History of Astronomy*, pt. ii, ch. 9, p. 375. (Bl., 1893.)

3566. UNIVERSE NOT MERELY MATTER AND FORCE— *Contains at Least One Rational and Conscious Being.*—The universe does not consist merely of insensate matter and force and automatic vitality: there happens to be in it the rational and consciously responsible being, man.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 27. (A. B. P. S.)

3567. UPLIFTING, GRADUAL, OF CONTINENTS— *Rise of a Century Measured by Inches.*—Perhaps it may be said that there is no analogy between the slow upheaval of broad plains or table-lands and the manner in which we must presume all mountain chains, with their inclined strata, to have originated. It seems, however, that the Andes have been rising century after century, at the rate of several feet, while the pampas on the east have been raised only a few inches in the same time. Crossing from the Atlantic to the Pacific, in a line passing through Mendoza, Mr. Darwin traversed a plain 800 miles broad, the eastern part of which has emerged from beneath the sea at a very modern period. The slope from the Atlantic is at first very gentle, then greater, until the traveler finds, on reaching Mendoza, that he has gained, almost insensibly, a height of 4,000 feet. The mountainous district then begins suddenly, and its breadth from Mendoza to the

shores of the Pacific is 120 miles, the average height of the principal chain being from 15,000 to 16,000 feet, without including some prominent peaks, which ascend much higher. Now all we require, to explain the origin of the principal inequalities of level here described, is to imagine, first, a zone of more violent movement to the west of Mendoza, and, secondly, to the east of that place, an upheaving force, which died away gradually as it approached the Atlantic. In short, we are only called upon to conceive that the region of the Andes was pushed up four feet in the same period in which the pampas near Mendoza rose one foot, and the plains near the shores of the Atlantic one inch. In Europe we have learned that the land at the North Cape ascends about five feet in a century, while farther to the south the movements diminish in quantity first to a foot, and then, at Stockholm, to three inches in a century, while at certain points still farther south there is no movement.—Lyell *Principles of Geology*, bk. i, ch. 1, p. 171. (A., 1854.)

3568. UPROAR OF LIFE IN TROPICAL FOREST—*Profusion of Nature Made Audible—Stillness in England Deathlike by Contrast.*—As we continued our walk the brief twilight commenced, and the sounds of multifarious life came from the vegetation around. The whirring of cicadas; the shrill stridulation of a vast number and variety of field crickets and grasshoppers, each species sounding its peculiar note; the plaintive hooting of tree-frogs—all blended together in one continuous ringing sound—the audible expression of the teeming profusion of Nature. As night came on, many species of frogs and toads in the marshy places joined in the chorus; their croaking and drumming, far louder than anything I had before heard in the same line, being added to the other noises, created an almost deafening din. This uproar of life, I afterward found, never wholly ceased, night or day: in course of time I became, like other residents, accustomed to it. It is, however, one of the peculiarities of a tropical—at least a Brazilian—climate which is most likely to surprise a stranger. After my return to England, the deathlike stillness of summer days in the country appeared to me as strange as the ringing uproar did on my first arrival at Pará.—Bates *Naturalist on the Amazon*, ch. 1, p. 625. (Hum., 1880.)

3569. USE AND ORNAMENT CONNECTED—*Curves of Movement Are Forms of Beauty.*—The harmonies on which all beauty probably depends are so minutely connected in Nature that use and ornament may often both arise out of the same conditions. Thus, some of the most beautiful lines on the surface of shells are simply the lines of their annual growth, which growth has followed definite curves, and it is the law of these curves that is beautiful in our eyes. Again, the forms of many fish which are so beautiful are also forms founded on the lines of least resistance. The same observation applies to the form of the bodies and of the wings of birds. Throughout Nature ornament is perpetually the result of conditions and arrangements fitted to use and contrived for the discharge of function. But the same principle applies to human art, and few persons are probably aware how many of the mere ornaments of architecture are the traditional representation of parts which had their origin in essential structure. Yet who would argue from this fact that ornament is not a special aim in the works of man? When the savage carves the handle of his war-club the immediate purpose of his carving is to give his own hand a firmer hold. But any shapeless scratches would be enough for this. When he carves it in an elaborate pattern he does so for the love of ornament, and to satisfy the sense of beauty.—Argyll *Reign of Law*, ch. 4, p. 115. (Burt.)

3570. USEFULNESS OF THE CROW—*An Insectivorous Bird—High Intelligence of the Corvidæ.*—There are systematists who think that the members of this family [the *Corvidæ*, including crows, jays, etc.] should hold the place usually assigned the thrushes, at the head of the class *Aves* [birds]. Leaving out of the case anatomical details whose value is disputed, we might object to a family of songless birds being given first rank in a group whose leading character is power of song. But while crows and jays may from a musical standpoint be considered songless, no one can deny their great vocal powers. Song, after all, does not imply high rank in bird-life. . . . . If, however, the relative intelligence . . . be taken into account, there can be no doubt that the *Corvidæ* fully deserve to be considered the most highly developed of birds. . . .

Crows share with hawks the reputation of being harmful birds. That they do much damage in the corn field is undeniable, but, after the examination of nine hundred crows' stomachs, Dr. Merriam, of the Department of Agriculture, states that the amount of good done by the crow in destroying grasshoppers, May-beetles, cutworms, and other injurious insects exceeds the loss caused by the destruction of corn. Moreover, if the corn be tarred before planting, the crows will not touch either the kernel or young sprout.—Chapman *Bird-Life*, ch. 7, p. 161. (A., 1900.)

3571. USES OF DARKNESS—*Fraunhofer's Lines Give New Meaning to the Spectrum.*—The gaseous spectra present a different appearance when the gas is in front of an ignited solid whose temperature is far higher than that of the gas. The observer sees then a continuous spectrum of a solid, but traversed by fine dark lines, which are just visible in the places in which the gas alone, seen in front of a dark background, would show bright lines. The solar spec-

trum is of this kind, and also that of a great number of fixed stars. The dark lines of the solar spectrum, originally discovered by Wollaston, were first investigated and measured by Fraunhofer, and are hence known as Fraunhofer's lines.—HELMHOLTZ *Popular Lectures*, lect. 4, p. 153. (L. G. & Co., 1898.)

3572. UTILITARIANISM COMMENDABLE—*The End the Measure of the Utility.*—What is a utilitarian? Simply one who prefers the useful to the useless—and who does not? But what is the useful? That which is prized, not on its own account, but as conducive to the acquisition of something else—the useful is, in short, only another word for a mean towards an end; for every mean is useful, and whatever is useful is a mean. Now the value of a mean is always in proportion to the value of its end; and the useful being a mean, it follows that, of two utilities, the one which conduces to the more valuable end will be itself the more valuable utility.

So far there is no difference of opinion. All agree that the useful is a mean towards an end; and that, *cæteris paribus*, a mean towards a higher end constitutes a higher utility than a mean towards a lower. The only dispute that has arisen or can possibly arise in regard to the utility of means (supposing always their relative efficiency) is founded on the various views that may be entertained in regard to the existence and comparative importance of ends.—HAMILTON *Metaphysics*, lect. 1, p. 3. (G. & L., 1859.)

3573. UTILITY AND INUTILITY OF FEAR—In fact, the teleology of fear, beyond a certain point, is very dubious. Professor Mosso, in his interesting monograph, "La Paura" (which has been translated into French), concludes that many of its manifestations must be considered pathological rather than useful; Bain, in several places, expresses the same opinion; and this, I think, is surely the view which any observer without a priori prejudices must take. A certain amount of timidity obviously adapts us to the world we live in, but the fear-paroxysm is surely altogether harmful to him who is its prey.—JAMES *Psychology*, vol. ii, ch. 24, p. 419. (H. H. & Co., 1899.)

3574. UTILITY AND PROGRESS—*Key of the Baconian Philosophy—Ancient Philosophy Despised the Practical.*—Two words form the key of the Baconian doctrine — utility and progress. The ancient philosophy disdained to be useful, and was content to be stationary. It dealt largely in theories of moral perfection, which were so sublime that they never could be more than theories; in attempts to solve insoluble enigmas; in exhortations to the attainment of unattainable frames of mind. It could not condescend to the humble office of ministering to the comfort of human beings. All the schools regarded that office as degrading; some censured it as immoral. Once indeed Posidonius, a distinguished writer of the age of Cicero and Cæsar, so far forgot himself as to enumerate among the humbler blessings which mankind owed to philosophy the discovery of the principle of the arch and the introduction of the use of metals. This eulogy was considered as an affront, and was taken up with proper spirit. Seneca vehemently disclaims these insulting compliments. Philosophy, according to him, has nothing to do with teaching men to rear arched roofs over their heads. The true philosopher does not care whether he has an arched roof or any roof. Philosophy has nothing to do with teaching men the use of metals. She teaches us to be independent of all material substances, of all mechanical contrivances. The wise man lives according to Nature. Instead of attempting to add to the physical comforts of his species, he regrets that his lot was not cast in that golden age when the human race had no protection against the cold but the skins of wild beasts, no screen from the sun but a cavern. To impute to such a man any share in the invention or improvement of a plow, a ship, or a mill is an insult.—MACAULAY *Essays (Lord Bacon)*, p. 271. (A., 1876.)

3575. UTILITY COMBINED WITH BEAUTY—*Palms, Bananas, and Ferns.*—Palms, bananas, and arborescent ferns constitute three forms of especial beauty peculiar to every portion of the tropical zone; wherever heat and moisture cooperate, vegetation is most exuberant and vegetable forms present the greatest diversity. Hence South America is the most beautiful portion of the palm world. . . . In the basin of the Orinoco whole tribes find the means of subsistence for many months together in the fruit of the palm.—HUMBOLDT *Views of Nature*, p. 303. (Bell, 1896.)

3576. UTILITY COMPELS EXACTNESS—*Practical Results To Be Won or Lost—Mere Disputation Content with Unproved Premises.*—By stimulating men to the discovery of new truth Bacon stimulated them to employ the inductive method, the only method—even the ancient philosophers and the schoolmen themselves being judges—by which new truth can be discovered. By stimulating men to the discovery of useful truth he furnished them with a motive to perform the inductive process well and carefully. His predecessors had been anticipators of Nature. They had been content with first principles, at which they had arrived by the most scanty and slovenly induction. And why was this? It was, we conceive, because their philosophy proposed to itself no practical end, because it was merely an exercise of the mind. A man who wants to contrive a new machine or a new medicine has a strong motive to observe accurately and patiently, and to try experiment after experiment. But a man who merely wants

a theme for disputation or declamation has no such motive. He is therefore content with premises grounded on assumption, or on the most scanty and hasty induction. Thus, we conceive, the schoolmen acted. On their foolish premises they often argued with great ability; and as their object was "*assensum subjugare, non res*"—to be victorious in controversy, not to be victorious over Nature—they were consistent. For just as much logical skill could be shown in reasoning on false as on true premises. But the followers of the new philosophy, proposing to themselves the discovery of useful truth as their object, must have altogether failed of attaining that object if they had been content to build theories on superficial induction.—MACAULAY *Essays (Lord Bacon)*, p. 283. (A., 1876.)

3577. UTILITY, DISCOVERY OF UNEXPECTED—*Nature Sifts the Food of Insectivorous Plants—Marginal Spikes of Venus's Fly-trap—Escape of Useless Insects Provided for.*—We are now prepared to understand the use of the marginal spikes which form so conspicuous a feature in the appearance of the plant [*Dionæa muscipula*, or Venus's fly-trap], and which at first seemed to me in my ignorance useless appendages. From the inward curvature of the lobes as they approach each other the tips of the marginal spikes first intercross, and ultimately their bases. Until the edges of the lobes come into contact, elongated spaces between the spikes, varying from the $\frac{1}{15}$ to the $\frac{1}{10}$ of an inch (1.693 to 2.54 mm.) in breadth, according to the size of the leaf, are left open. Thus an insect, if its body is not thicker than these measurements, can easily escape between the crossed spikes, when disturbed by the closing lobes and increasing darkness; and one of my sons actually saw a small insect thus escaping. A moderately large insect, on the other hand, if it tries to escape between the bars, will surely be pushed back again into its horrid prison with closing walls, for the spikes continue to cross more and more until the edges of the lobes come into contact. . . . Now it would manifestly be a great disadvantage to the plant to waste many days in remaining clasped over a minute insect, and several additional days or weeks in afterwards recovering its sensibility, inasmuch as a minute insect would afford but little nutriment. It would be far better for the plant to wait for a time until a moderately large insect was captured, and to allow all the little ones to escape; and this advantage is secured by the slowly intercrossing marginal spikes, which act like the large meshes of a fishing-net, allowing the small and useless fry to escape.—DARWIN *Insectivorous Plants*, ch. 13, p. 252. (A., 1900.)

3578. UTILITY, ENDEAVOR TO ATTAIN—*Magnetism Converted into Electricity—Faraday's Words.*—Faraday's reply to those who saw nothing gained by the development of the little [electric] spark, and who demanded its utility, was . . . sententious. "Endeavor to make it useful," he said. He left to others the immediate work of doing so. Some twenty-five years later he saw that tiny flash expanded into the magnificent blaze of the famous South Foreland lighthouse. To-day it illuminates the thoroughfares of the great cities of the civilized world.—PARK BENJAMIN *Age of Electricity*, ch. 7, p. 90. (S., 1897.)

3579. UTILITY, HIGHER AND LOWER—*Knowledge for the Sake of Man—Means Valued in Proportion to End.*—There are few, I believe, disposed to question the speculative dignity of mental science; but its practical utility is not unfrequently denied. To what, it is asked, is the science of mind conducive? What are its uses? I am not one of those who think that the importance of a study is sufficiently established when its dignity is admitted; for, holding that knowledge is for the sake of man, and not man for the sake of knowledge, it is necessary, in order to vindicate its value, that every science should be able to show what are the advantages which it promises to confer upon its student. I, therefore, profess myself a utilitarian; and it is only on the special ground of its utility that I would claim for the philosophy of mind what I regard as its peculiar and preeminent importance.—HAMILTON *Metaphysics*, lect. 1, p. 3. (G. & L., 1859.)

3580. UTILITY MORE THAN BEAUTY—*Classic Lamps—The Argand Burner.*—The Greek and Roman lamps, tho in beautiful receptacles of bronze or silver, were exactly the same in principle as those of the lowest savage, and hardly better in light-giving power; and tho various improvements in form were introduced, the first really important advance was made by the Argand burner. This introduced a current of air into the center of the flame as well as outside it, and, by means of a glass chimney, a regular supply of air was kept up, and a steady light produced. Altho the invention was made at the end of the last century, the lamps were not sufficiently improved and cheapened to come into use till about 1830; and from that time onward many other improvements were made, chiefly dependent on the use of the cheap mineral oils, rendering lamps so inexpensive, and producing so good a light that they are now found in the poorest cottages.—WALLACE *The Wonderful Century*, ch. 4, p. 28. (D. M. & Co., 1898.)

3581. UTILITY NOT THE SUPREME TEST—*Life a Power beyond Man's Measure of Use.*—After all, is this question of "use" really one which need concern us greatly in our studies of life? I trow not; for it surely indicates by no means a lofty conception of things if we are perpetually to

speak and think of living beings as we should talk of the items in a store. Each organism, like the smith in "The Fair Maid of Perth," fights for its own hand in the struggle for existence. If in the course of its fight it aids or opposes the interests of other living things it will receive benefit or incur failure in a meed corresponding to its own ways and means. This is really the true philosophy of natural history study. To "consider the lilies" as if they were mere contrivances for human ends and "uses" is a tolerably small-minded fashion of regarding the children of life. To know something of their histories, structure, and relationships, and thereby to learn how life jogs along its primrose way (or the reverse), is in itself an education worth much seeking-after and much painstaking care.—WILSON *Glimpses of Nature*, ch. 1, p. 7. (Hum., 1892.)

3582. ——— *Truth an End for Itself—Unexpected Utility Results.*—If you ask me, To what end?—of what use is such a discovery?—I answer, It is given to no mortal man to predict what may be the result of any discovery in the realms of Nature. When the electric current was discovered, what was it? A curiosity. When the first electric machine was invented, to what use was it put? To make puppets dance for the amusement of children. To-day it is the most powerful engine of civilization. But should our work have no other result than this—to know that certain facts in Nature are thus and not otherwise, that their causes were such and no others—this result in itself is good enough, and great enough, since the end of man, his aim, his glory, is the knowledge of the truth.—AGASSIZ *Journey in Brazil*, ch. 3, p. 95. (H. M. & Co., 1896.)

3583. UTILITY OF DIVERGENCE—*A Maximum of Organic Forms in Each Area.*—Divergence of character has a double purpose and use. In the first place it enables a species which is being overcome by rivals, or is in process of extinction by enemies, to save itself by adopting new habits or by occupying vacant places in Nature. This is the immediate and obvious effect of all the numerous examples of divergence of character which we have pointed out. But there is another and less obvious result, which is that the greater the diversity in the organisms inhabiting a country or district the greater will be the total amount of life that can be supported there.—WALLACE *Darwinism*, ch. 5, p. 77. (Hum.)

3584. UTILITY OF MICRO-ORGANISMS—*Bacteria Useful as Well as Harmful—Saprophytes and Parasites.*—A *saprophyte* is an organism that obtains its nutrition from dead organic matter. Its services, of whatever nature, lie outside the tissues of living animals. Its life is spent apart from a "host." A *parasite*, on the other hand, lives always at the expense of some other organism which is its host, in which it lives and upon which it lives. There is a third or intermediate group, known as "facultative," owing to their ability to act as parasites or saprophytes, as the exigencies of their life-history may demand.

The saprophytic organisms are, generally speaking, those which contribute most to the benefit of man, and the parasitic the reverse, tho this statement is only approximately true. In their relation to the processes of fermentation, decomposition, nitrification, etc., we shall see how great and invaluable is the work which saprophytic microbes perform. [See DECOMPOSITION, BACTERIA OF.]—NEWMAN *Bacteria*, ch. 1, p. 27. (G. P. P., 1899.)

3585. UTILITY SUBLIMATED TO USELESSNESS—*Humanity Not Guided by the Inconceivable.*—So long as the simple and natural meaning was put upon utility, and the good was identified with the pleasurable, or the serviceable, the utilitarian theory of morals did indicate at least some rule of life, however low that rule might be. But now that the apostles of that theory have been driven to put upon utility a transcendental meaning, and the pleasurable is interpreted to refer not merely to the immediate and visible effects of conduct on ourselves or others, but to its remotest effects upon all living beings, both now and for all future time, the utilitarian theory in this very process of sublimation becomes lifted out of the sphere of human judgment. If it be true "that there can be no correct idea of a part without a correct idea of the correlative whole," and if human conduct in its tendencies and effects is only "a part of universal conduct"—that is to say, of the whole system of the universe in its past, its present, and its future—then, as this whole is beyond all our means of knowledge and comprehension, it follows that utility, in this sense, can be no guide to us.—ARGYLL *Unity of Nature*, ch. 9, p. 208. (Burt.)

3586. UTILITY, UNEXPECTED—*Conspicuous Coloring Protective—Zebra Almost Invisible in Twilight.*—It may be thought that such extremely conspicuous markings as those of the zebra would be a great danger in a country abounding with lions, leopards, and other beasts of prey; but it is not so. Zebras usually go in bands, and are so swift and wary that they are in little danger during the day. It is in the evening or on moonlight nights, when they go to drink, that they are chiefly exposed to attack; and Mr. Francis Galton, who has studied these animals in their native haunts, assures me that in twilight they are not at all conspicuous, the stripes of white and black so merging together into a gray tint that it is very difficult to see them at a little distance. We have here an admirable illustration of how a glaringly conspicuous style of marking for recog-

nition may be so arranged as to become also protective at the time when protection is most needed; and we may also learn how impossible it is for us to decide on the inutility of any kind of coloration without a careful study of the habits of the species in its native country.—WALLACE *Darwinism*, ch. 8, p. 149. (Hum.)

3587. ——— ——— *Scientific Toy Gives Roentgen Rays.*—There are thousands of facts which are discovered which seem to have no interest, near or remote, to the welfare of humanity, and yet the discovery and recording of these facts must sometime and somehow prove useful.

In chemistry we have many illustrations of this idea. Many years ago Professor Crookes, by producing a vacuum far greater than had ever been accomplished before, discovered certain properties of energy which he called radiant matter. For nearly twenty years Crookes' tubes have been a physical toy devoted more to the entertainment than the instruction of classes in light, heat, and electricity. The vanes of mica, blackened on one side, and revolving without any apparent cause, seem to be almost a realization of the chimera of perpetual motion. With wonderful skill and ingenuity Professor Crookes investigated the elusive properties of this fourth state of matter, a space from which almost all energy was excluded, save that of the unthinkable ether itself. Who, even a few months ago, would have supposed that these truly marvelous researches of Crookes could possibly have any direct influence upon men and things? Yet we see now through the marvelous discovery of Professor Roentgen an application of Professor Crookes's discovery which, in its possibilities of benefit to suffering humanity, has not been surpassed by any single invention of the last hundred years.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 18).

3588. UTILIZATION OF WASTE PRODUCTS—*Bleaching-powder Made to Lock Up Noxious Gas.*—Formerly the chemist when he wished to obtain sodium extracted it from common salt and discharged the chlorin gas into the air. It was found that in establishments where the manufacture of sodium was conducted on a large scale the destructive properties of the chlorin discharged into the air were such that all vegetation was killed for some distance around the manufactory. This came to be such a nuisance that the manufacturers were either compelled to stop business or in some way take care of the chlorin. This is done at the present day by uniting the chlorin gas with common lime, forming a chlorid of lime, which is used for bleaching and purifying purposes.—ELISHA GRAY *Nature's Miracles*, vol. i, ch. 5, p. 37. (F. H. & H., 1900.)

3589. ——— ——— *Colors from Coal-tar.*—Through the discoveries of the great Hoffmann and afterwards by the investigations of other chemists, the dyeing interests of the world have been completely revolutionized. From that most unpromising substance, coal-tar, at one time considered an almost worthless residue of the manufacture of gas, nearly all the colors which now find a use in the arts have been derived.—WILEY *Relations of Chemistry to Industrial Progress (Address at Purdue University, Lafayette, Ind., 1896*, p. 17).

3590. VAGARIES, PHILOSOPHICAL, OF SCIENTISTS—*Importations of Theories into Scripture—Imagined "Conflict of Religion and Science."*—One fruitful cause of difficulty in the relations of science and religion is to be found in the narrowness and incapacity of well-meaning Christians who unnecessarily bring the doctrines of natural and revealed religion into conflict, by misunderstanding the one or the other, or by attaching obsolete scientific ideas to Holy Scripture, and identifying them with it in points where it is quite non-committal. Much mischief is also done by a prevalent habit of speaking of all, or nearly all, the votaries of science as if they were irreligious. A second cause is to be found in the extravagant speculations indulged in by the adherents of certain philosophical systems. Such speculations often far overpass the limits of actual scientific knowledge, and are yet paraded before the ignorant as if they were legitimate results of science, and so become irretrievably confounded with it in the popular mind.—DAWSON *Facts and Fancies in Modern Science*, lect. 1, p. 15. (A. B. P. S.)

3591. VAGUENESS OF ORDINARY KNOWLEDGE—*Ideas of a Babe—Layman at Shipwreck, Battle, or Fire.*—All our knowledge at first is vague. When we say that a thing is vague, we mean that it has no subdivisions *ab intra*, nor precise limitations *ab extra*; but still all the forms of thought may apply to it. It may have unity, reality, externality, extent, and what-not—*thinghood*, in a word, but thinghood only as a whole. In this vague way, probably, does the room appear to the babe who first begins to be conscious of it as something other than his moving nurse. It has no subdivisions in his mind, unless, perhaps, the window is able to attract his separate notice. In this vague way, certainly, does every entirely new experience appear to the adult. A library, a museum, a machine-shop, are mere confused wholes to the uninstructed, but the machinist, the antiquary, and the bookworm perhaps hardly notice the whole at all, so eager are they to pounce upon the details. Familiarity has in them bred discrimination. . . . A layman present at a shipwreck, a battle, or a fire is helpless. Discrimination has been so little awakened in him by experience that his consciousness

leaves no single point of the complex situation accented and standing out for him to begin to act upon. But the sailor, the fireman, and the general know directly at what corner to take up the business. They "see into the situation"—that is, they analyze it—with their first glance. It is full of delicately differenced ingredients which their education has little by little brought to their consciousness, but of which the novice gains no clear idea.—JAMES *Psychology*, vol. ii, ch. 22, p. 343. (H. H. & Co., 1890.)

3592. VALE OF FIREFLIES—*Air Laden with Phosphorescent Odor.*—Riding on the pampas one dark evening an hour after sunset, and passing from high ground overgrown with giant thistles to a low plain covered with long grass, bordering a stream of water, I found it all ablaze with myriads of fireflies. I noticed that all the insects gave out an exceptionally large, brilliant light, which shone almost steadily. The long grass was thickly studded with them, while they literally swarmed in the air, all moving up the valley with a singularly slow and languid flight. When I galloped down into this river of phosphorescent fire my horse plunged and snorted with alarm. I succeeded at length in quieting him, and then rode slowly through, compelled to keep my mouth and eyes closed, so thickly did the insects rain on to my face. The air was laden with the sickening phosphorous smell they emit; but when I had once got free of the broad fiery zone, stretching away on either hand for miles along the moist valley, I stood still and gazed back for some time on a scene the most wonderful and enchanting I have ever witnessed.—HUDSON *Naturalist in La Plata*, ch. 13, p. 173. (C. & H., 1895.)

3593. VALLEY LIFELESS AND SILENT—*Scenery of the Val del Bove, Mount Etna.*—This plain has been deluged by repeated streams of lava; and altho it appears almost level when viewed from a distance, it is in fact more uneven than the surface of the most tempestuous sea. . . .

An unusual silence prevails; for there are no torrents dashing from the rocks nor any movement of running water in this valley, such as may almost invariably be heard in mountainous regions. Every drop of water that falls from the heavens, or flows from the melting ice and snow, is instantly absorbed by the porous lava; and such is the dearth of springs that the herdsman is compelled to supply his flocks, during the hot season, from stores of snow laid up in hollows of the mountain during winter.

The strips of green herbage and forest land which have here and there escaped the burning lavas serve, by contrast, to heighten the desolation of the scene. When I visited the valley, nine years after the eruption of 1819, I saw hundreds of trees, or rather the white skeletons of trees, on the borders of the black lava, the trunks and branches being all leafless and deprived of their bark by the scorching heat emitted from the melted rock; an image recalling those beautiful lines:

> As when heaven's fire
> Hath scath'd the forest oaks, or mountain pines,
> With singed top their stately growth, tho bare,
> Stands on the blasted heath.

—LYELL *Principles of Geology*, bk. ii, ch. 25, p. 405. (A., 1854.)

3594. VALLEY PARTITIONED BY MEETING DELTAS—The separation of lakes Brienz and Thun, Switzerland, has been cited by Davis as an example of the partitioning of a valley by the union of deltas from opposite sides. Interlaken stands on the beautiful alluvial plain thus formed. Several other similar examples in central Europe have been described by various authors.—RUSSELL *Lakes of North America*, ch. 1, p. 7. (G. & Co., 1895.)

3595. VALLEYS HOLLOWED BY GLACIERS—*Ice, Sand, and Water Combine to Wear Away Rocks.*—In the case of every glacier we have two agents at work—the ice exerting a crushing force on every point of its bed which bears its weight, and either rasping this point into powder or tearing it bodily from the rock to which it belongs; while the water which everywhere circulates upon the bed of the glacier continually washes the detritus away and leaves the rock clean for further abrasion. Confining the action of glaciers to the simple rubbing away of the rocks, and allowing them sufficient time to act, it is not a matter of opinion, but a physical certainty, that they will scoop out valleys.—TYNDALL *Hours of Exercise in the Alps*, ch. 20, p. 238. (A., 1898.)

3596. VALUE OF LEAST PROMISING ELEMENT—*The Layer of Scum and Mud the Most Important Part of Filter.*—Koch maintained that the portion of the filter-bed which really removed micro-organisms effectively was the slimy organic layer upon the surface. This layer is produced by a deposit from the still unpurified water lying immediately above it. The most vital part of the filter-bed is this organic layer, which, after formation, should not be disturbed until it requires removal owing to its impermeability. . . . The only vital part of the [filtration] process . . . is the chemical effect of the layer of scum and mud on the surface of the sand at the top of the filter-bed. The mechanical part of this layer is, of course, the holding back of the particulate matter which has not subsided in the reservoir; the vital action consists in what is termed nitrification of unoxidized substance, which is accomplished in this layer of organic matter.—NEWMAN *Bacteria*, ch. 2, p. 75. (G. P. P., 1899.)

3597. VALUE OF SIMPLICITY—*Plain Food Best for Constant Use—Codfish Used Like Bread—The Bonito of the Mediterranean.*—By boiling out the rich oil of

the salmon, the Norwegian reduces it nearly to the condition of codfish, concerning which I learned a curious fact from two old Dogger Bank fishermen with whom I had a long sailing cruise from the Golden Horn to the Thames. They agreed in stating that codfish is like bread, that they and all their mates lived upon it (and sea-biscuits) day after day for months together, and never tired, while richer fish ultimately became repulsive if eaten daily. This statement was elicited by an immediate experience. We were in the Mediterranean, where bonito were very abundant, and every morning and evening I amused myself by spearing them from the martingale of the schooner, and so successfully that all hands (or rather mouths) were abundantly supplied with this delicious dark-fleshed, full-blooded, and high-flavored fish. I began by making three meals a day on it, but at the end of about a week was glad to return to the ordinary ship's fare of salt junk and chickens.—WILLIAMS *Chemistry of Cookery*, ch. 3, p. 29. (A., 1900.)

3598. VALUE OF THE MINUTE THINGS—*Bacteria Essentially Beneficial—Man's Perversion of Nature Makes Them Noxious.*—We learn, too, another lesson from this latest discovery of the secrets of the living universe. . . . For these minute bacteria of various kinds are present everywhere—in the air, in the water, in the soil under our feet. Their function appears to be to break up by putrefactive processes all dead organized matter, and thus prepare it for being again assimilated by plants, so as to form food for animals and for man; and it seems probable that they prepare the soil itself for plant-growth by absorbing and fixing the nitrogen of the atmosphere. They are, in fact, omnipresent, and under normal conditions they are wholly beneficial. It is we ourselves who, by our crowded cities, our polluted streams, and our unnatural and unwholesome lives, enable them to exert their disease-creating powers.—WALLACE *The Wonderful Century*, ch. 14, p. 146. (D. M. & Co., 1899.)

3599. VALUE OF THE UNKNOWN AND HIDDEN—*Utility of the Earth's Mass—Stability Depends on Gravity—Difference of Weight on the Earth and on Mars.*—A body which would weigh 27 pounds on the earth would, if removed to Mars, weigh only 10 pounds. . . . Whewell remarks that in such a case "we should discover the want of the usual force of gravity by the instability of all about us. Things would not lie where we placed them, but would slide away with the slightest push. We should have a difficulty in standing or walking, something like what we have on shipboard when the deck is inclined; and we should stagger helplessly through an atmosphere thinner than that which oppresses the respiration of the traveler on the tops of the highest mountains." And he very well notes that all this shows the real importance of those dark and unknown central portions of the earth which we are apt to regard as "deposits of useless lumber without effect or purpose. We feel their influence on every step we take and on every breath we draw; and the powers we possess and the comforts we enjoy would be unprofitable to us if they had not been prepared with reference to those as well as to the near and visible portions of the earth's mass."—PROCTOR *Expanse of Heaven*, p. 71. (L. G. & Co., 1897.)

3600. VARIABILITY GENERAL AMONG PLANTS AND ANIMALS—Individual variability is a general character of all common and wide-spread species of animals or plants; and, further, . . . this variability extends, so far as we know, to every part and organ, whether external or internal, as well as to every mental faculty. Yet more important is the fact that each part or organ varies to a considerable extent independently of other parts. Again, we have shown by abundant evidence that the variation that occurs is very large in amount—usually reaching 10 or 20, and sometimes even 25 per cent. of the average size of the varying part; while not 1 or 2 only, but from 5 to 10 per cent. of the specimens examined exhibit nearly as large an amount of variation.—WALLACE *Darwinism*, ch 3, p. 58. (Hum.)

3601. VARIABILITY OF ADJUSTMENT—*Constancy of Force Admits Variety of Adaptation—Contrivance in Constitution of the Universe.*—The superstition which saw in all natural phenomena the action of capricious deities was not more irrational than the superstition which sees in them nothing but the action of invariable law. Men have been right, and not wrong, when they saw in the facts of Nature the variability of adjustment even more clearly and more surely than they saw the constancy of force. They were right when they identified these phenomena with the phenomena of mind. They were right when they regarded their own faculty of contrivance as the nearest and truest analogy by which the constitution of the universe can be conceived and its order understood. They were right when they regarded its arrangements as susceptible of change, and when they looked upon a change of will as the efficient cause of other changes without number and without end. It was well to feel this by the force of instinct; it is better still to be sure of it in the light of reason. It is an immense satisfaction to know that the result of logical analysis does but confirm the testimony of consciousness, and run parallel with the primeval traditions of belief.—ARGYLL *Reign of Law*, ch. 7, p. 231. (Burt.)

3602. VARIABILITY IN THE COMBINATION OF FORCES—*Will Finds Room in the Variation.*—When . . . scientific men speak, as they often do, of all phenomena

being governed by invariable laws, they use language which is ambiguous, and in most cases they use it in a sense which covers an erroneous idea of the facts. There are no phenomena visible to man of which it is true to say that they are governed by any invariable force. That which does govern them is always some variable combinations of invariable forces. But this makes all the difference in reasoning on the relation of will to law—this is the one essential distinction to be admitted and observed. There is no observed order of facts which is not due to a combination of forces; and there is no combination of forces which is invariable—none which are not capable of change in infinite degrees.—ARGYLL *Reign of Law*, ch. 2, p. 59. (Burt.)

3603. VARIATION IN THE ACTION OF EROSIVE FORCES—*Currents, Tides, Waves, Elevation and Depression of Lands.*—We can explain why the intensity of the force of aqueous causes should be developed in succession in different districts. Currents, for example, tides, and the waves of the sea, cannot destroy coasts, shape out or silt up estuaries, break through isthmuses, and annihilate islands, form shoals in one place and remove them from another, without the direction and position of their destroying and transporting power becoming transferred to new localities. Neither can the relative levels of the earth's crust above and beneath the waters vary from time to time, as they are admitted to have varied at former periods, and as it will be demonstrated that they still do, without the continents being, in the course of ages, modified, and even entirely altered, in their external configuration. Such events must clearly be accompanied by a complete change in the volume, velocity, and direction of the streams and land floods to which certain regions give passage. That we should find, therefore, cliffs where the sea once committed ravages, and from which it has now retired; estuaries where high tides once rose, but which are now dried up; valleys hollowed out by water, where no streams now flow, is no more than we should expect; these and similar phenomena are the necessary consequences of physical causes now in operation; and if there be no instability in the laws of Nature, similar fluctuations must recur again and again in time to come.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 344. (A., 1854.)

3604. VARIATION OF MAGNETIC NEEDLE—*Its Correspondence with Sun-spots—Needle in Cellar at Paris Responds to Aurora Borealis in Sweden and Norway.*—Our planet is alive with a certain stellar life which we cannot yet sufficiently understand. Magnetic currents circulate in it, and incessantly, under their mysterious influence, the magnetic needle seeks the north with its restless and agitated finger. The intensity and direction of these currents vary day by day, year by year, century by century. . . . Here is an important secular variation which has caused many maritime disasters to pilots who are ignorant of it. We may add that every day this curious needle deviates from its magnetic meridian towards the east at eight o'clock in the morning, and towards the west at one o'clock in the afternoon. The extent of this variation varies year by year, and, what is truly surprising, this variation appears to correspond with the number of spots visible on the sun; it is in the years when there are most spots that this fluctuation is most marked. The number of auroræ boreales seems likewise connected with the state of the day-star. Indeed, the magnetic needle enclosed in a cellar of the Paris Observatory follows the aurora borealis which lights its aerial fires in Sweden and Norway. It is restless, agitated—I might say, feverish; more than that, infatuated—and its disturbance only ceases when the distant meteor has disappeared. What books like the book of Nature! And how strange it is that it has so few readers!—FLAMMARION *Popular Astronomy*, bk. i, ch. 6, p. 67. (A.)

3605. VARIATION OF ORGANISMS FROM COMMON TYPE—*Varieties of the Apple.*—All our apples are known to have descended from the common crab of our hedges *(Pyrus Malus)*, and from this at least a thousand distinct varieties have been produced. These differ greatly in the size and form of the fruit, in its color, and in the texture of the skin. They further differ in the time of ripening, in their flavor, and in their keeping properties; but apple-trees also differ in many other ways. The foliage of the different varieties can often be distinguished by peculiarities of form and color, and it varies considerably in the time of its appearance.—WALLACE *Darwinism*, ch. 4, p. 62. (Hum.)

3606. VARIATION OF STARLIGHT IN TRAVERSING EARTH'S ATMOSPHERE—*Scintillation Diminishes with Altitude—Tranquillity of the Stars as Seen from a Balloon.*—The light which reaches us from the stars is subject, in traversing our atmosphere, to slight variations of aspect, according to its original intensity, its vivacity, its tint; in a word, according to its own nature. The higher we rise in the air, the more the scintillation diminishes. At the tops of mountains it appears very feeble. During the nights which I have had the pleasure of passing in a balloon I have been surprised at the calm and majestic tranquillity of the celestial torches, which seemed to correspond with the silence and profound solitude by which I was surrounded.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 6, p. 607. (A.)

3607. VARIATION THE RULE IN NATURE—*All Qualities Affected by It.*—The experience of breeders and cultivators . . .

proves that variation is the rule instead of the exception, and that it occurs, more or less, in almost every direction. This is shown by the fact that different species of plants and animals have required different kinds of modification to adapt them to our use, and we have never failed to meet with variation in that particular direction, so as to enable us to accumulate it and so to produce ultimately a large amount of change in the required direction.—WALLACE *Darwinism*, ch. 4, p. 61. (Hum.)

3608. VARIETIES MUST PRECEDE SELECTION—*Natural Selection Not a Cause—Darwin's Admission.*—To me it seems that Professor Huxley and his followers in this line of argument have entirely overlooked the consideration, that before natural selection among varietal forms could come into operation, there must have been varieties to select from—that for the "fittest" to have survived, they must have come to possess the structure that made them the fittest. It was very early pointed out that natural selection only expresses a general fact, and can in no sense be accounted a *vera causa;* and this, in his later years, Mr. Darwin showed himself quite willing to admit. In what I believe to be his last public utterance on the subject, he spoke of the causes of variation as at present the greatest problem of biological science; and the greater our success in the investigation of it, the more surely—I feel convinced—shall we recognize the evidences of an originating design.—CARPENTER *Nature and Man*, lect. 15, p. 436. (A., 1889.)

3609. VARIETIES OF DOGS—*Not Found in Wild State.*—The numerous races of dogs which we have produced by domesticity are nowhere to be found in a wild state. In Nature we should seek in vain for mastiffs, harriers, spaniels, greyhounds, and other races, between which the differences are sometimes so great that they would be readily admitted as specific between wild animals; "yet all these have sprung originally from a single race, at first approaching very near to a wolf, if, indeed, the wolf be not the true type which at some period or other was domesticated by man." —LYELL *Principles of Geology*, bk. iii, ch. 33, p. 570. (A., 1854.)

3610. VARIETIES SCORNED BY THE OLDER NATURALISTS—*Now Sought and Cherished.*—By the older naturalists, indeed, varieties—especially if numerous, small, and of frequent occurrence—were looked upon as an unmitigated nuisance, because they rendered it almost impossible to give precise definitions of species, then considered the chief end of systematic natural history. Hence it was the custom to describe what was supposed to be the "typical form" of species, and most collectors were satisfied if they possessed this typical form in their cabinets. Now, however, a collection is valued in proportion as it contains illustrative specimens of all the varieties that occur in each species, and in some cases these have been carefully described, so that we possess a considerable mass of information on the subject.—WALLACE *Darwinism*, ch. 3, p. 28. (Hum.)

3611. VARIETY IN THE UNIVERSE—*Aggregations of Stars—Different Magnitudes Intermingled—The Milky Way.*—Here, then, is fresh evidence of the wonderful constitution of the Milky Way. We see that this complicated aggregation of star-streams—for such is the true description of the galaxy—consists in the main of a multitude of relatively minute stars, amidst which many stars, so large as to be visible to the naked eye, are scattered, while also stars of intermediate orders are gathered with great richness in the same region of space. It follows that when Sir W. Herschel was endeavoring by means of his powerful telescopes to resolve the cloudy light of the Milky Way into separate stars he was not really penetrating, as he supposed, to the remotest limits of our stellar system, and bringing into view stars which were at a relatively enormous distance, but in many cases at least was simply scrutinizing more and more closely certain definite aggregations of stars, of many orders of real magnitude, all intermixed together in the same region of space. . . . Our stellar universe, in fact, no longer presents the uniform aspect which it had assumed as interpreted by Sir W. Herschel, but shows varieties of structure and of aggregation corresponding with, but far surpassing in degree, those which we recognize in the solar system.—PROCTOR *Expanse of Heaven*, p. 273. (L. G. & Co., 1897.)

3612. ——— ——— *Creation Not Held to the Single Model of Our Sun and Solar System—Pairs and Clusters of Suns of Varying Color and Brightness.*—The most beautiful contrasts of coloring are not presented by the systems in rapid motion, but by the systems in slow motion, and even in those which have remained motionless since their discovery. This curious fact does not prevent the planets which gravitate round these latter suns from being subject to the most singular alternations of illumination, of seasons, and of years. Our white and solitary sun, our solar system formed with a single focus round which revolve obedient worlds, following regular orbits, does not constitute the type and the model of universal creation. The multiple suns which we study here sometimes unite their light, sometimes oppose each other, sometimes alternate successively in the same sky; suns of dissimilar volumes and masses, acting often in contrary directions and distorting the singular orbits of the unknown worlds which gravitate in their power. No spectacle is more magnificent than the telescopic contemplation of these strange suns. When in the

silent night, during the sleep of terrestrial Nature, in those nocturnal hours when humanity around us is asleep in anticipated death, our gaze and our thoughts are elevated by the aid of the marvelous telescope towards these celestial lights which are lit up on high from other worlds, and radiate around them heat, activity, and life, the contrast is so great that we think we dream. Here night, above light; here lethargy, above motion; here shadows, above splendor; here heavy and dark matter, above the devouring flame and the sidereal life.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 9, p. 638. (A.)

3613. ——— ——— *Cycles of Revolution of Stellar Systems.*—Notwithstanding the enormous distances which separate these stars [of one system] from each other, yet vaster distances, or rather distances of a higher order of vastness, separate that system of stars from the surrounding parts of the galaxy. It presents to us, also, the wonderful thought that cycles of revolution must exist within that system, compared with which the longest periods of motion recognized within our solar system must be regarded as absolutely insignificant. We are shown in such star-systems an order of created things unlike any that before we had known. One other form of evidence has been given to show the infinite variety which pervades every part of the universe. —PROCTOR *Expanse of Heaven*, p. 296. (L. G. & Co., 1897.)

3614. ——— ——— *Stars and Nebulæ Intermingled in Same Great Group.*—There is no maintaining nebulæ to be simply remote worlds of stars, in the face of an agglomeration like the Nubecula Major, containing in its (certainly capacious) bosom both stars and nebulæ. Add the evidence of the spectroscope to the effect that a large proportion of these perplexing objects are gaseous, with the intimate relation obviously subsisting between the mode of their scattering and the lie of the Milky Way, and it becomes impossible to resist the conclusion that both nebular and stellar systems are parts of a single scheme.—CLERKE *History of Astronomy*, pt. ii, ch. 12, p. 505. (Bl., 1893.)

3615. ——— ——— *The Heavens Transfigured.*—Science is only beginning to penetrate into the starry immensity. Even yesterday we were ignorant of the number of the real double stars now observed, the diversity of their motions, and their proportion in the organization of the heavens. We may estimate that about one-fifth of the suns of which the universe is composed are not single, like that which illuminates us, but associated in binary, ternary, or multiple systems. Thus the double stars are veritable suns, gigantic and powerful, governing, in the regions illuminated by their splendor, systems different from that of which we form part. The sky is no longer a gloomy desert; its ancient solitudes have given place to regions peopled like those in which the earth gravitates; the darkness, the silence and death which reigned in these depths have given place to light, to motion, and to life; thousands and millions of suns pour out in great waves into space the energy, the heat, and the different undulations which emanate from their foci; the universe is transfigured to our thoughts; suns succeed to suns, worlds to worlds, universes to universes; tremendous proper motions carry all these systems through the endless regions of immensity; and everywhere, out to and beyond the farthest limits where the fatigued imagination may rest its wings, everywhere is developed in infinite variety the divine creation in which our microscopical planet is but an insignificant province.—FLAMMARION *Popular Astronomy*, bk. vi, ch. 8, p. 640. (A.)

3616. ——— ——— *Varying Length of Years.*—What inexhaustible variety distinguishes the planets from each other! On the moon, for example, there are but twelve days and twelve nights in a year, and yet their year is of the same length as ours. Here we count 365 days in a year. On Jupiter the year is nearly twelve times longer than ours, and the day less than half the terrestrial day; hence it follows that there are no less than 10,455 days in the year of that world! On Saturn the disproportion is still more extraordinary; for its year, thirty times longer than ours, contains 25,217 days. And what shall we say of Neptune, whose year lasts for a century and a half—165 of our rapid years! If biology is there regulated in the same proportions, a young girl of seventeen years on Neptune would really have lived 2,800 of our years; she would have lived nearly a thousand years before Christ was born in Judea; she would have been contemporary with Romulus, Julius Cæsar, Constantine, Clovis, Charlemagne, François I., Louis XIV., Robespierre—and she would still be only seventeen! Lethargic fiancée, she will marry in three or four hundred years a young man of her dreams aged himself more than three thousand terrestrial years.—FLAMMARION *Popular Astronomy*, bk. i, ch. 2, p. 13. (A.)

3617. VARIETY IN UNITY—*Similarity in Structure of Diverse Parts.*—The similar framework of bones in the hand of a man, wing of a bat, fin of the porpoise, and leg of the horse—the same number of vertebræ forming the neck of the giraffe and of the elephant—and innumerable other such facts, at once explain themselves on the theory of descent with slow and slight successive modifications. The similarity of pattern in the wing and in the leg of a bat, tho used for such different purpose, in the jaws and legs of a crab, in the petals, stamens, and pistils of a flower, is likewise, to a large extent, intelligible on the view of the gradual modification of parts or organs.

which were aboriginally alike in an early progenitor in each of these classes.—DARWIN *Origin of Species*, ch. 15, p. 494. (Burt.)

3618. VARIETY OF COLOR AMONG THE STARS—*Double Stars of Complementary Colors.*—A careful examination of the bright double stars . . . teaches that, besides white, all the colors of the solar spectrum are to be found in the double stars, but that the principal star, whenever it is not white, approximates in general to the red extreme (that of the least refrangible rays), but the companion to the violet extreme (the limit of the most refrangible rays). The reddish stars are twice as frequent as the blue and bluish; the white are about two and a half times as numerous as the red and reddish. It is moreover remarkable that a great difference of color is usually associated with a corresponding difference in brightness. In two cases—in ζ Bootis and γ Leonis—which, from their great brightness, can easily be measured by powerful telescopes, even in the daytime, the former consists of two white stars of the third and fourth magnitudes, and the latter of a principal star of the second, and of a companion of the 3.5th magnitude. This is usually called the brightest double star of the northern hemisphere, whereas α Centauri and α Crucis, in the southern hemisphere, surpass all the other double stars in brilliancy. . . . "This superb double star (α Centauri) is beyond all comparison the most striking object of the kind in the heavens, and consists of two individuals, both of a high ruddy or orange color, tho that of the smaller is of a somewhat more somber and brownish cast." (Sir John Herschel, "Observations at the Cape of Good Hope," p. 300.)—HUMBOLDT *Cosmos*, vol. iii, p. 209. (H., 1897.)

3619. VARIETY OF COLOR IN DEEP-SEA ECHINODERMS—*Compared to Autumn Leaves.*—It is impossible to account for [the] extraordinary variety of color in the deep-sea echinoderms. It is hardly probable that it can be protective or warning in function, and it is difficult to suppose that it is due to any peculiar excretory process. Whether it is due in any way to the influence of the environment, or, like the color of autumn leaves, to the chemical degeneration of colors that in the shallow-water ancestry were functional, are problems that must be left for the future to decide.—HICKSON *Fauna of the Deep Sea*, ch. 4, p. 64. (A., 1894.)

3620. VARIETY OF MOVEMENT OF COMETS—*Celestial Visitors Captives of Sun's Attraction.*—Four principal characteristics distinguish comets from planets: (1) Their nebulous aspect and their tails, often considerable; (2) the length of the elliptical orbits which they describe; (3) the inclination of these orbits, which, instead of lying in the plane of the ecliptic, or at least in the zodiac, like those of the planets in general, are inclined at all degrees up to a right angle, and sometimes carry the comets to the polar constellations; (4) the directions of their motions, which, instead of being performed in the same direction as those of planets, are, some direct, others retrograde, and appear to be strangers to any unity of plan. From these circumstances the certain conclusion follows that comets have not the same origin as the planets, that they did not originally belong to the solar system, that they travel through immensity, that they may be transported from one sun to another (from star to star), and that those which revolve round our sun have been caught in their passage by his attraction, having had their course curved and closed by the influence of the planets of our system.—FLAMMARION *Popular Astronomy*, bk. v, ch. 2, p. 489. (A.)

3621. VARIETY OF NATURE—*Aurora Ranges from Low Elevation Up to Hundreds of Miles.*—From all this evidence we are entitled to conclude that the altitude of polar auroras varies within very wide limits, and that, in spite of the opinion of certain authors, it is certainly possible to observe auroral manifestations quite near the surface of the earth. . . .

But let us distinguish. In mean latitudes, in France and Central Europe, all measurements of the height of the aurora have always given very high numbers [by some observers in some instances estimated at more than 500 miles]. . . . It is only in latitudes above the 55th or 60th parallel that auroras are undoubtedly found at a much lower level, and sometimes even quite near the surface of the earth. It seems, then, lawful to assume that the mean height at which the aurora is produced diminishes as we approach the poles. Perhaps exceeding 100 kilometers (60 miles) in low latitudes, it descends to some tens of miles in the arctic regions, and may even be quite near the ground.—ANGOT *Aurora Borealis*, ch. 4, p. 68. (A., 1897.)

3622. ——— ——— *Close Observation Finds Endless Differences—Shepherd Knows Individual Sheep.*—If we look about us in a forest consisting of only a single species of tree, for example, of beech, we shall certainly not find in the whole forest two trees of this kind which are absolutely identical or perfectly equal in the form of their branches, the number of their branches, and leaves, blossoms, and fruits. Special differences occur everywhere, just as in the case of men. There are no two men who are absolutely identical, perfectly equal in size, in the formation of their faces, the number of their hairs, their temperament, character, etc. The very same is true of individuals of all the different species of animals and plants. It is true that in most organisms the differences are very trifling to the eye of the uninitiated. Everything here essen-

tially depends on the exercise of the faculty of discovering these often very minute differences of form. The shepherd, for example, knows every individual of his flock, solely by accurately observing their peculiarities, while the uninitiated are incapable of distinguishing at all the different individuals of one and the same flock.—HAECKEL *History of Creation*, vol. i, ch. 7, p. 158. (K. P. & Co., 1899.)

3623. —— —— *Results Wrought from a Few Elements—As Language from the Alphabet.*—The number of substances deemed elementary has varied with the advance of science; but as compared with the variety of their products, that number may be considered as infinitesimally small; whilst the progress of analysis, with glimpses of laws as yet unknown, renders it almost certain that this number will be found to be smaller still. Yet out of that small number of elementary substances, having fixed rules, too, limiting their combination, all the infinite varieties of organic and inorganic matter are built up by means of nice adjustment. As all the faculties of a powerful mind can utter their voice in language whose elements are reducible to twenty-four letters, so all the forms of Nature, with all the ideas they express, are worked out from a few simple elements having a few simple properties.—ARGYLL *Reign of Law*, ch. 2, p. 57. (Burt.)

3624. VARIETY OF TONES AMONG ANIMALS—*Darwin's Six Modulations in the Bark of the Dog—From These May Spring a Full Vocabulary.*—The howl of the dog, the neigh of the horse, the bleat of the lamb, the stamp of the goat, and other signs are all readily understood by other animals. One monkey utters at least six different sounds to express its feelings; and Mr. Darwin has detected four or five modulations in the bark of the dog: "the bark of eagerness, as in the chase; that of anger as well as growling; the yelp or howl of despair when shut up; the baying at night; the bark of joy when starting on a walk with his master; and the very distinct one of demand or supplication, as when wishing for a door or window to be opened." Now these signs are as much language as spoken words. You have only to evolve this to get all the language the dictionary-maker requires.—DRUMMOND *Ascent of Man*, p. 158. (J. P., 1900.)

3625. VASTNESS, SENSE OF—*Plainsman's First Experience of a Hill.*—I remember my first experience of a hill, after having been shut within "these narrow limits." It was one of the range of Sierras near Cape Corrientes, and not above eight hundred feet high; yet, when I had gained the summit, I was amazed at the vastness of the earth, as it appeared to me from that modest elevation. Persons born and bred on the pampas, when they first visit a mountainous district, frequently experience a sensation as of "a ball in the throat," which seems to prevent free respiration.—HUDSON *Naturalist in La Plata*, ch. 1, p. 5. (C. & H., 1895.)

3626. VAULT OF HEAVEN—*Ancients Regarded the Heavens as Made of Glass—The "Crystal Sphere."*—Altho, according to Stobæus and the collector of the "Views of the Philosophers," the designation "crystal vault of heaven" dates as far back as the early period of Anaximenes, the first clearly defined signification of the idea on which the term is based occurs in Empedocles. This philosopher regarded the heaven of the fixed stars as a solid mass, formed from the ether which had been rendered crystalline and rigid by the action of fire. According to his theory, the moon is a body conglomerated (like hail) by the action of fire, and receives its light from the sun. The original idea of transparency, congelation, and solidity would not, according to the physics of the ancients, and their ideas of the solidification of fluids, have referred directly to cold and ice; but the affinity between κρύσταλλος, κρύος, and κρυσταίνω, as well as this comparison with the most transparent of all bodies, gave rise to the more definite assertion that the vault of heaven consisted of ice or of glass. Thus we read in Lactantius: "Cœlum aërem glaciatum esse" and "vitreum cœlum." Empedocles undoubtedly did not refer to the glass of the Phenicians, but to air, which was supposed to be condensed into a transparent solid body by the action of the fiery ether. In this comparison with ice (κρύσταλλος), the idea of transparency predominated, no reference being here made to the origin of ice through cold, but simply to its conditions of transparent condensation. While poets used the term crystal, prose writers . . . limited themselves to the expression crystalline or crystal-like, κρυσταλλοειδής. In like manner, πάγος (from πήγνυσθαι, to become solid) signifies a piece of ice—its condensation being the sole point referred to.—HUMBOLDT *Cosmos*, vol. iii, p. 123. (H., 1897.)

3627. VEGETATION AND CRYSTALLIZATION—*Lake of the Solfatara—Contrast of the Animate and the Inanimate.*—In the Campagna, between Rome and Tivoli, is the Lake of the Solfatara, called also Lago di Zolfo *(lacus albula)*, into which flows continually a stream of tepid water from a smaller lake, situated a few yards above it. The water is a saturated solution of carbonic-acid gas, which escapes from it in such quantities in some parts of its surface that it has the appearance of being actually in ebullition. "I have found by experiment," says Sir Humphry Davy, "that the water taken from the most tranquil part of the lake, even after being agitated and exposed to the air, contained in solution more than its own volume of carbonic-acid gas, with a very small quantity of sulfureted hydrogen. Its

high temperature, which is pretty constant at 80° F., and the quantity of carbonic acid that it contains, render it peculiarly fitted to afford nourishment to vegetable life. The banks of travertin are everywhere covered with reeds, lichen, confervæ, and various kinds of aquatic vegetables; and at the same time that the process of vegetable life is going on the crystallizations of the calcareous matter, which is everywhere deposited in consequence of the escape of carbonic acid, likewise proceed. There is, I believe, no place in the world where there is a more striking example of the opposition or contrast of the laws of animate and inanimate Nature, of the forces of inorganic chemical affinity, and those of the powers of life."

The same observer informs us that he fixed a stick in a mass of travertin covered by the water in the month of May, and in April following he had some difficulty in breaking, with a sharp-pointed hammer, the mass which adhered to the stick, and which was several inches in thickness. The upper part was a mixture of light tufa and the leaves of confervæ; below this was a darker and more solid travertin, containing black and decomposed masses of confervæ; in the inferior part the travertin was more solid, and of a gray color, but with cavities probably produced by the decomposition of vegetable matter.—LYELL *Principles of Geology*, bk. ii, ch. 16, p. 243. (A., 1854.)

3628. VEGETATION, GIGANTIC, OF TROPICS—*A Forest of Arum.*—One of the islands was low and sandy, and half of it was covered with gigantic arum-trees, the often-mentioned *Caladium arborescens*, which presented a strange sight. Most people are acquainted with the little British species *Arum maculatum*, which grows in hedge-bottoms, and many, doubtless, have admired the larger kinds grown in hot-houses; they can therefore form some idea of a forest of arums. On this islet the woody stems of the plants near the bottom were eight to ten inches in diameter, and the trees were twelve to fifteen feet high, all growing together in such a manner that there was just room for a man to walk freely between them. There was a canoe inshore, with a man and a woman; the man, who was hooting with all his might, told us in passing that his son was lost in the "aningal" (arum-grove). He had strayed while walking ashore, and the father had been an hour waiting for him in vain. —BATES *Naturalist on the River Amazon*, ch. 5, p. 664. (Hum., 1880.)

3629. VEGETATION, MICROSCOPIC—*The "Red Snow" of the Alps.*—Sometimes, in the midst of the wide expanse, one comes upon a patch of the so-called red snow of the Alps. At a distance one would say that such a spot marked some terrible scene of blood, but, as you come nearer, the hues are so tender and delicate, as they fade from deep red to rose, and so die into the pure colorless snow around, that the first impression is completely dispelled. This red snow is an organic growth, a plant springing up in such abundance that it colors extensive surfaces, just as the microscopic plants dye our pools with green in the spring. It is an alga *(Protocoites nivalis)*, well known in the arctics, where it forms wide fields in the summer.—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 227. (H. M. & Co., 1896.)

3630. VELOCITY OF LIGHT—*Exactness of Newcomb's Observations—Rays Sent Across a Measured Space.*—All earlier efforts of the kind were thrown into the shade by Professor Newcomb's arduous operations at Washington in 1880-1882. The scale upon which they were conducted was in itself impressive. Foucault's entire apparatus in 1862 had been enclosed in a single room; Newcomb's revolving and fixed mirrors, between which the rays of light were to run their timed course, were set up on opposite shores of the Potomac, at a distance of nearly four kilometers [about 2½ miles]. This advantage was turned to the utmost account by ingenuity and skill in contrivance and execution; and the deduced velocity of 299,860 kilometers (=186,328 miles) a second had an estimated error (30 kilometers [18.63 miles]) only one-tenth that ascribed by Cornu to his own result in 1874. —CLERKE *History of Astronomy*, pt. ii, ch. 6, p. 297. (Bl., 1893.)

3631. ———— ———— *Happy Conjecture of Bacon.*—The second book of Lord Bacon's "Novum Organum" gives us the earliest views on the velocity of light and the probability of its requiring a certain time for its transmission. He speaks of the time required by a ray of light to traverse the enormous distances of the universe, and proposes the question whether those stars yet exist which we now see shining. We are astonished to meet with this happy conjecture in a work whose intellectual author was far behind his contemporaries in mathematical, astronomical, and physical knowledge. The velocity of reflected solar light was first measured by Römer (November, 1675) by comparing the periods of occultation of Jupiter's satellites; while the velocity of the direct light of the fixed stars was ascertained (in the autumn of 1727) by means of Bradley's great discovery of aberration, which afforded objective evidence of the translatory movement of the earth, and of the truth of the Copernican system.— HUMBOLDT *Cosmos*, vol. iii, p. 80. (H., 1897.)

3632. VELOCITY OF OCEAN CURRENTS — *Narrowing of Channel Increases Speed of Crowded Waters.*—The ordinary velocity of the principal currents of the ocean is from one to three miles per hour; but when the boundary lands converge, large bodies of water are driven gradually into a narrow space, and then wanting lateral room

are compelled to raise their level. Whenever this occurs their velocity is much increased. The current which runs through the Race of Alderney, between the island of that name and the mainland, has a velocity of about eight English miles an hour. Captain Hewett found that in the Pentland Firth the stream, in ordinary spring tides, runs ten miles and a half an hour, and about thirteen miles during violent storms. The greatest velocity of the tidal current through the "Shoots" or New Passage, in the Bristol Channel, is fourteen English miles an hour; and Captain King observed, in his survey of the Straits of Magellan, that the tide ran at the same rate through the "First Narrows," and about eight geographical miles an hour in other parts of those straits.—LYELL *Principles of Geology*, bk. ii, ch. 19, p. 293. (A., 1854.)

3633. VELOCITY, UNIMAGINABLE, OF ELECTRICITY—*Emblem of Speed of Thought—Moving Bodies Seen Motionless.*—A flash of lightning cleaves a cloud, appearing and disappearing in less than a hundred-thousandth of a second, and the velocity of electricity is such as would carry it in a single second over a distance almost equal to that which separates the earth and moon. It is well known that a luminous impression once made upon the retina endures for about one-sixth of a second, and that this is the reason why we see a continuous band of light when a glowing coal is caused to pass rapidly through the air. A body illuminated by an instantaneous flash continues to be seen for the sixth of a second after the flash has become extinct; and if the body thus illuminated be in motion, it appears at rest at the place where the flash falls upon it. When a color-top with differently colored sectors is caused to spin rapidly the colors blend together. Such a top, rotating in a dark room and illuminated by an electric spark, appears motionless, each distinct color being clearly seen. Professor Dove has found that a flash of lightning produces the same effect. During a thunder-storm he put a color-top in exceedingly rapid motion, and found that every flash revealed the top as a motionless object, with its colors distinct.—TYNDALL *Fragments of Science*, vol. i, ch. 21, p. 440. (A., 1900.)

3634. VENOM ADAPTED TO VICTIM—*One Plan Must Comprehend Destroyer and Destroyed.*—The poison of a deadly snake—let us for a moment consider what this is. It is a secretion of definite chemical properties which have reference, not only—not even mainly—to the organism of the animal in which it is developed, but specially to the organism of another animal which it is intended to destroy. Some naturalists have a vague sort of notion that, as regards merely mechanical weapons, or organs of attack, they may be developed by use—that legs may become longer by fast running, teeth sharper and longer by much biting. Be it so: this law of growth, if it exist, is but itself an instrument whereby purpose is fulfilled. But how will this law of growth adjust a poison in one animal with such subtle knowledge of the organization of another that the deadly virus shall in a few minutes curdle the blood, benumb the nerves, and rush in upon the citadel of life? There is but one explanation—a Mind, having minute and perfect knowledge of the structure of both, has designed the one to be capable of inflicting death upon the other. This mental purpose and resolve is the one thing which our intelligence perceives with direct and intuitive recognition. The method of creation, by means of which this purpose has been carried into effect, is utterly unknown.—ARGYLL *Reign of Law*, ch. 1, p. 21. (Burt.)

3635. VENTILATION IS LIFE—*Deadly Products of Combustion—Breathing Is Combustion without Flame.*—We often take great precautions to prevent its [carbon dioxid or carbonic acid] escape. Scared by the ghosts of rheumatism and neuralgia, some people in winter close the doors of their apartments and stop up every crevice by which fresh air can enter or foul air escape.

By means of a sandbag at the window, another at the door, and a piece of list carefully tacked along its edge, the whole arrangement being supplemented by a screen, the products of combustion and exhalation are kept circulating in the room and breathed over and over again by those within, at the cost of morning headache, languor, and depression, with a long train of other evils following in the wake. From the fire, from the lights, and from the lungs of the inmates, the poisonous gas is evolved, and must be removed by efficient ventilation. We are here struck by the remarkable analogy between the process of combustion and the function of respiration.

The latter is, in fact, a species of combustion without flame. The carbon of the impure venous blood unites with the oxygen of the air to form carbonic acid gas, while the hydrogen unites with another portion of oxygen to form water. Both products are expelled at each exhalation, and the chemical action going on within the body raises its temperature to nearly 100°.—LOWE *Nature-Studies*, p. 4. (Hum., 1888.)

3636. VENTRILOQUISM IN NATURAL MAGIC—*Judgment of Distance Relative.*—A change of wind, an unusual stillness in the air, is quite sufficient to produce the sense that sounding objects are nearer than they actually are. The art of the ventriloquist manifestly aims at producing this kind of illusion. By imitating the dull effect of a distant voice, he is able to excite in the minds of his audience a powerful conviction that the sounds proceed from a distant point. There is little doubt that ventriloquism has played a conspicuous part in the arts of divination and magic.—SULLY *Illusions*, ch. 5, p. 82. (A., 1897.)

3637. VENUS'S FLY-TRAP—*Remarkable Mechanism for Securing Insect Food—Plant Almost without Roots—Leaves Spring upon Prey at a Touch.*—This plant [*Dionæa muscipula*], commonly called Venus's fly-trap, from the rapidity and force of its movements, is one of the most wonderful in the world. It is a member of the small family of the *Droseraceæ*, and is found only in the eastern part of North Carolina, growing in damp situations. The roots are small; those of a moderately fine plant which I examined consisted of two branches about one inch in length, springing from a bulbous enlargement. They probably serve, as in the case of *Drosera*, solely for the absorption of water; for a gardener, who has been very successful in the cultivation of this plant, grows it, like an epiphytic orchid, in well-drained damp moss without any soil. . . . The two lobes stand at rather less than a right angle to each other. Three minute pointed processes or filaments, placed triangularly, project from the upper surfaces of both; but I have seen two leaves with four filaments on each side, and another with only two. These filaments are remarkable from their extreme sensitiveness to a touch, as shown not by their own movement, but by that of the lobes. The margins of the leaf are prolonged into sharp, rigid projections which I will call spikes, into each of which a bundle of spiral vessels enters. The spikes stand in such a position that, when the lobes close, they interlock like the teeth of a rat-trap.—DARWIN *Insectivorous Plants*, ch. 13, p. 232. (A., 1900.)

3638. VERACITY OF ANCIENT TRAVELER VINDICATED—*The Sea of Seaweed.*—His ships, he [Himilco, a Carthaginian explorer of the sixth century B. C.] says, or at least Avienus says for him, were "surrounded by seaweed." Where was he when this took place? All that we can say in answer to this question is that he sailed through the Pillars of Hercules into the Atlantic Ocean, and we know that few days' sail in this direction would have brought him to the "Mare di Sargasso," a sea which has actually taken its name from the quantity of seaweed *(sargasso)* growing in it. Sir G. C. Lewis says, "The notion of remote seas being impassable by ships, either from their shoals, or from the obstacles to navigation produced by the semifluid and muddy properties of the water, frequently recurs among the ancients"; and it is true, no doubt, that statements of this kind are made by many ancient writers, as, for instance, by Herodotus, Plato, Scylax, and even Aristotle; but not one of these writers alludes to "seaweed" as an impediment to navigation, and it can hardly be accidental that the only voyager by whom this is referred to was one who sailed on a course which, if persevered in for a few days, would have brought him to that which is even now known as the Sea of Seaweed.—AVEBURY *Prehistoric Times*, ch. 3, p. 59. (A., 1900.)

3639. —— —— *Unknown Substance Found Covering the Sea—Plates of Ice Like Jellyfish.*—Round the island of Thule Pytheas [a Greek explorer, third century B. C., treated by Polybius, Strabo, and later writers as a mendacious imposter] saw a substance which was neither earth, air, nor water, but a substance resembling medusæ or jellyfishes (πνεύμονι θαλασσίῳ ἐοικὸς), which could neither be passed on foot nor in ships. This passage, which has completely puzzled southern commentators, is justly regarded by Professor Nilsson as a striking evidence of Pytheas's veracity. For when the Northern Ocean freezes, this does not happen as in our ponds or lakes, but small, separate plates of ice are formed, and as soon as this process commences the fishermen hurry to the shore, lest they should be caught in the ice, which for some time is too thick to permit the passage of a boat, yet too weak to support the weight of a man. A very similar description is given by Captain Lyon. "We came," he says, "amongst young ice, in that state called sludge, which resembles in appearance and consistency a far better thing—lemon ice. From this we came to small round plates, of about a foot in diameter, which have the appearance of the scales of gigantic fishes." Richardson also particularly mentions the "circular plates of ice, six or eight inches in diameter." These disks of ice tossed about by the waves suggested to Professor Nilsson himself, when he first saw them, the idea of a crowd of medusæ, and if we imagine a southerner who had never before witnessed such a phenomenon, and who on his return home wished to describe it to his fellow countrymen, it would have been difficult to find an apter or more ingenious simile. It is, moreover, one which would hardly have occurred to any one who had not witnessed the actual phenomenon.—AVEBURY *Prehistoric Times*, ch. 3, p. 62. (A., 1900.)

3640. VERIFICATION OF POPULAR BELIEF—*Naturalist's Observation—Vampire and Horse.*—The vampire-bat is often the cause of much trouble, by biting the horses on their withers. The injury is generally not so much owing to the loss of blood as to the inflammation which the pressure of the saddle afterwards produces. The whole circumstance has lately been doubted in England; I was therefore fortunate in being present when one . . . was actually caught on a horse's back. We were bivouacking late one evening near Coquimbo, in Chile, when my servant, noticing that one of the horses was very restive, went to see what was the matter, and fancying he could distinguish something, suddenly put his hand on the beast's withers and secured the vampire. In the morning the spot where the bite had been inflicted was easily distin-

guished from being slightly swollen and bloody.—DARWIN *Naturalist's Voyage around the World,* ch. 2, p. 22. (A., 1898.)

3641. VERSATILITY OF SCIENTIST —*Mastery of Three Great Departments—The Philosophic Mind Everywhere at Home.* —Wherever mineralogy or geology is taught, the unsurpassed text-books on these subjects by Dana hold easy supremacy. . . . Of his mineralogy Powell says: "Thus he was the first to give us a system of mineralogy; but his work in this field did not end at that stage. He still pursued his investigations, collecting from many fields, and drawing from the collections of many others in many lands, until at last he developed a new system of mineralogy, placing the science on an enduring basis. This accomplishment alone was also worthy of a great man, and by it a new science was organized on a mathematical, chemical, and physical basis."

The broader field of geology became his after his return from the exploring expedition, and he published his "Manual of Geology" in 1862. . . . Concerning his valuable work on geology Powell said: "So Dana's 'Geology' is not only a text-book of geology, but it is the handbook for all national, state, and local geologists and all students in the field. It is the universal book of reference in that department of science. Other text-books have been developed, but no other handbook for America. It is a vast repository of facts, but all arranged in such a manner as to constitute a geologic philosophy. It is on every worker's table, and is carried in the kit of every field observer. It has thus become the standard to which all scientific research is referred, and on which geologic reports are modeled."

Besides the foregoing, Dana was the author of "Coral Reefs and Islands," which he enlarged and published later as "Corals and Coral Islands"; of "The Geological Story Briefly Told"; "The Characteristics of Volcanoes," and "The Four Rocks of the New Haven Region."

In conclusion Powell says of him: "Dana as a zoologist was great, Dana as a mineralogist was greater, but Dana as a geologist was greatest, and Dana in all three was a philosopher; hence Dana's great work is enduring.—MARCUS BENJAMIN *Early Presidents of the American Association* in *Proceedings of Amer. Assoc. for the Advancement of Science, 1899,* p. 16.

3642. VICES OF SAVAGERY NOT PRIMEVAL—*Cannibalism and Infanticide.*—There is an assumption that the further we go back in time there was not only less and less extensive knowledge of the useful arts —not only simpler and simpler systems of life and polity—but also that there were deeper and deeper depths of the special characteristics of the modern savage. We have, however, only to consider what some of these characteristics are to be convinced that, altho they may have arisen in early times, they cannot possibly have existed in the times which were the earliest of all. . . . If, for example, there ever was a time when there existed on one spot of earth, or even on more spots than one, a single pair of human beings, it is impossible that they should have murdered their offspring or that they should have killed and eaten each other. Accordingly it is admitted that cannibalism and infanticide, two of the commonest practises of savage and of barbarous life, cannot have been primeval. But this is a conclusion of immense significance. It hints to us, if it does no more, that what is true of one savage practise may possibly be true of others. It breaks down the presumption that whatever is most savage is therefore probably the most ancient.—ARGYLL *Unity of Nature,* ch. 10, p. 228. (Burt.)

3643. VICTIM OF BOA OR PYTHON DESTITUTE OF FEAR—We have often observed boas and pythons do this [kill their victims by crushing] in captivity, and can affirm that the rabbits and ducks introduced into their cages are entirely destitute of fear or apprehension, and suffer nothing until they are seized, and then their sufferings are extremely brief. Such a serpent, if disposed to feed—to attain which disposition it often needs a fast of several weeks—will move slowly about till it brings its mouth opposite to the muzzle of the rabbit. Then in an instant its mouth is opened and the rabbit's head is seized, while simultaneously the voluminous folds of the powerful body are twined round it, and it is crushed immediately to death. The serpent does not at once uncoil its folds, but continues for a time tightly to embrace its victim, so that reanimation becomes impossible.—MIVART *Types of Animal Life,* ch. 5, p. 141. (L. B. & Co., 1893.)

3644. VICTIM UNWARNED—*Infection Unsuspected—Incubation Period of Typhoid.*—Until intoxication [*i. e.,* toxin poisoning] occurs there may be few or no symptoms, but directly enough bacteria are present to produce in the body certain poisons in sufficient amount to result in more or less marked tissue change, then the symptoms of that tissue change appear. This period of latency between infection and the appearance of the disease is known as the incubation period. Take typhoid, for example. A man drinks a typhoid-polluted water. For about fourteen days the bacilli are making headway in his body without his being aware of it. But at the end of that incubation period the signs of the disease assert themselves.—NEWMAN *Bacteria,* ch. 8, p. 271. (G. P. P., 1899.)

3645. VICTORY OF THE MAMMALS IN ANCIENT STRUGGLE—*Nature Ever Since Perfecting This Highest Type.*—The development of complete mammality was no sudden thing. The results of the struggle

are registered in the Eocene rocks. The ancient world had found its Waterloo. Gone were the dragons who so long had lorded it over both hemispheres—brontosaurs, iguanodons, plesiosaurs, lælaps, pterodactyls—all gone; their uncouth brood quite vanished from the earth, and nothing left alive as a reminder, save a few degenerate, collateral kin, such as snakes and crocodiles, objects of dread and loathing to higher creatures. Never in the history of our planet has there been a more sweeping victory than that of the mammals, nor has Nature had any further occasion for victories of that sort. The mammal remains the highest type of animal existence, and subsequent progress has been shown in the perfecting of that type where most perfectible.—FISKE *Through Nature to God*, pt. ii, ch. 11, p. 125. (H. M. & Co., 1900.)

3646. VIEW, ANCIENT, OF FIXED STARS—*Stars Supposed To Be Riveted to the Vault of Heaven—The "Crystal Sphere."*—The inappropriate expression of fixed stars (*astra fixa* of Manilius) reminds us . . . of the connection, or, rather, confusion of the ideas of insertion, and of absolute immobility or fixity. When Aristotle calls the non-wandering celestial bodies (ἀπλανῆ ἄστρα) riveted (ἐνδεδεμένα), when Ptolemy designates them as ingrafted (προσπεφυκότες), these terms refer specially to the idea entertained by Anaximenes of the crystalline sphere of heaven. The apparent motion of all the fixed stars from east to west, while their relative distances remain unchanged, had given rise to this hypothesis. "The fixed stars (ἀπλανῆ ἄστρα) belong to the higher and more distant regions, in which they are riveted, like nails, to the crystalline heavens; the planets (ἄστρα πλανώμενα or πλανητά), which move in an opposite direction, belong to a lower and nearer region." [Stobæus, "Eclog. Phys.," p. 582.]—HUMBOLDT *Cosmos*, vol. iii, p. 122. (H., 1897.)

3647. VIRTUE AMONG SAVAGES—*Names Wanting for Love and Gratitude.*—Neither faith, hope, nor charity enters into the virtues of a savage. The Sichuana language contains no expression for thanks; the Algonquin had no word for love; the Tinnè no word for beloved; mercy was with the North-American Indians a mistake, and peace an evil; theft, says Catlin, they "call capturing"; humility is an idea which they could not comprehend. Among the Koupouees the greatest misconduct, says Major McCulloch, "is to forgive an enemy, the first virtue is revenge."—AVEBURY *Prehistoric Times*, ch. 15, p. 541. (A., 1900.)

3648. VIRTUES, PATERNAL, DIFFERENT FROM MATERNAL—*As Necessary to the Race—Heredity Blends the Two.*—The acquisitions of the manly life are as necessary to human character as the virtues which gather their sweetness by the cradle; and these robuster elements—strength, courage, manliness, endurance, self-reliance—could only have been secured away from domestic cares. Apart from that, it was not necessary to put the father through the same mill as the mother. Whatever the mother gained would be handed on to her boys as well as to her girls, and with the law of heredity to square accounts, it was unnecessary for each of the two great sides of humanity to make the same investments. By one acquiring one set of virtues and the other another, the blend in the end would be the richer; and, without obliterating the eternal individualities of each, the measure of completeness would be gained more quickly for the race. Before heredity, however, could do its work upon the father a certain basis had to be laid. With his original habits he would squander the hereditary gains as fast as he received them, and unless some change was brought about in his mode of life the old wild blood in his veins would counteract the gentler influence, and leave all the mother's work in vain. Hence Nature had to set about another long and difficult process—to make the savage father a reformed character.—DRUMMOND *Ascent of Man*, ch. 9, p. 293. (J. P., 1900.)

3649. VIRULENCE OF BACTERIA INCREASED BY ASSOCIATION—*Banded Evils Most Deadly.*—The virulence of . . . bacteria is . . . increased by means of association. The *Bacillus coli* is an example; for, in conjunction with other organisms, this bacillus, altho normally present in health in the alimentary canal, is able to set up acute intestinal irritation, and various changes in the body of an inflammatory nature. It is not yet possible to say in what way or to what degree the association of bacteria influences their rôle. That is a problem for the future. But whilst we have examples of this association in streptococcus and the bacillus of diphtheria, *B. coli* and yeasts, tetanus and putrefactive bacteria, *Diplococcus pneumoniæ* and streptococcus, and association amongst the various suppurative organisms, we cannot doubt that there is an explanation to be found here of many hitherto unsolved results of bacterial action.—NEWMAN *Bacteria*, ch. 1, p. 32. (G. P. P., 1899.)

3650. VISIBLE VS. ACTUAL—*Other Worlds than Ours Like Lands Beyond the Sea.*—The world in which we live is a round ball of a determined magnitude, and occupies its own place in the firmament. But when we explore the unlimited tracts of that space which is everywhere around us, we meet with other balls of equal or superior magnitude, and from which our earth would either be invisible, or appear as small as any of those twinkling stars which are seen on the canopy of heaven. Why then suppose that this little spot, little at least in the immensity which surrounds it, should be the exclusive abode of life and of intelligence? What reason to think that those mightier globes which roll in other parts of

creation, and which we have discovered to be worlds in magnitude, are not also worlds in use and in dignity? Why should we think that the great Architect of Nature, supreme in wisdom as he is in power, would call these stately mansions into existence and leave them unoccupied? When we cast our eye over the broad sea, and look at the country on the other side, we see nothing but the blue land stretching obscurely over the distant horizon. We are too far away to perceive the richness of its scenery, or to hear the sound of its population. Why not extend this principle to the still more distant parts of the universe? What tho, from this remote point of observation, we can see nothing but the naked roundness of yon planetary orbs? Are we therefore to say that they are so many vast and unpeopled solitudes; that desolation reigns in every part of the universe but ours; that the whole energy of the divine attributes is expended on one insignificant corner of these mighty works; and that to this earth alone belongs the bloom of vegetation, or the blessedness of life, or the dignity of rational and immortal existence?—CHALMERS *Astronomical Discourses*, p. 21. (R. Ct., 1848.)

3651. ——— ——— *Stars Seem to Revolve around the Pole—The "Steadfast Polar Star" Changes Place in the Sky.*—If we watch the heavenly bodies for a few hours we shall always find them in motion, those in the east rising upwards, those in the south moving towards the west, and those in the west sinking below the horizon. We know that this motion is only apparent, arising from the rotation of the earth on its axis; but . . . we may speak of the motion as real. A few days' watching will show that the whole celestial sphere seems to revolve, as on an axis, every day. It is to this revolution, carrying the sun alternately above and below the horizon, that the alternations of day and night are due. The nature and effects of this motion can best be studied by watching the apparent movement of the stars at night. We should soon learn from such a watch that there is one point in the heavens, or on the celestial sphere, which does not move at all. In our latitudes this point is situated in the north, between the zenith and the horizon, and is called the pole. Around this pole, as a fixed center, all the heavenly bodies seem to revolve, each one moving in a circle, the size of which depends on the distance of the body from the pole. There is no star situated exactly at the pole, but there is one which, being situated little more than a degree distant, describes so small a circle that the unaided eye cannot see any change of place without making some exact and careful observation. This is therefore called the pole-star. . . . The altitude of the pole is equal to the latitude of the place.—NEWCOMB *Popular Astronomy*, pt. i, ch. 1, p. 9. (H., 1899.)

3652. VISION, BINOCULAR—*The Effect of Seeing with Two Eyes.*—In Nature we see every object with two eyes, each of which occupies a somewhat different standpoint in space. We therefore acquire two pictures of each separate object that we blend in our conception into one physical whole. That is why we see objects in Nature in so much greater relief than in painting.—KAAT *Leonardo da Vinci als Naturforscher.* (Translated for *Scientific Side-Lights.)*

3653. VISION, DEFECTIVE—*Color-blindness—Case of Dr. Dalton.*—The most interesting case of [color-blindness] is that of the celebrated chemical philosopher, Dr. Dalton, of England. He published an account of his own case and that of several others in the *Transactions* of the Manchester Society in 1794. Of the seven colors of the rainbow he could distinguish but two, yellow and blue; or at most, three, yellow, blue, and purple. He saw no difference between red and green; so that he thought the color of a laurel leaf the same as that of a stick of red sealing-wax. A story is told of his having, on one occasion, appeared at the Quaker meeting, of which he was a member, in the usual drab coat and small-clothes of the sect, with a pair of flaming red-colored stockings to match. Whatever may be the truth in reference to this story, we have the assertion of Professor Whewell that when Dr. Dalton was asked with what he would compare the scarlet gown with which he had been invested by the university, he pointed to the trees, and declared that he perceived no difference between the color of his robe and that of their foliage. —HENRY *Color Blindness (Scientific Writings,* vol. i, p. 236). (Sm. Inst., 1886.)

3654. VISION INDEPENDENT OF ARGUMENT OR CALCULATION—*Apparent and Real Size of Church Clock and Ball on Steeple.*—Vision requires to be convinced [through its own organs]. No assertion on the part of other people, no speculation or calculation is of influence in determining our perception, but only an association of ideas repeated over and over again. Isolated experiences, therefore, make no impression upon our minds. From a window in my room I look directly upon a neighboring church tower. The face of the church clock appears about as large as that of a moderately large clock which hangs upon my wall. The ball of the steeple looks about as large as the button of a flagstaff. A little while ago the clock face and steeple knob were taken down for repairs and lay upon the street. To my astonishment, I saw that the former was as large as a church door, and the latter as large as a wagon-wheel. Now the two are in their places again and look to me just as they did before, altho I have learned their true size. The workman upon the roof does not seem so much smaller than he actually is, because I have observed

the size of my fellow men hundreds of times. But the ball of a steeple and a church clock are not objects of every-day experience. The button of a flagstaff and the clock on the wall are much more familiar. And so I think of the steeple knob as the flagstaff button, and the church clock as a wall clock. —WUNDT *Psychology,* lect. 2, p. 179. (Son. & Co., 1896.)

3655. VISION, NEW POSSIBILITIES OF—*Roentgen Rays Make the Opaque Transparent.*—These [Roentgen] rays are produced by a special form of electrical current sent through a vacuum tube, in or around which is some fluorescent substance, which under the action of the current becomes intensely luminous. But this luminosity has totally different properties from ordinary light, inasmuch as the substances which are opaque or transparent to it are not the same as those to which we usually apply the terms, but often the very contrary. Paper, for instance, is so transparent that the rays will pass through a book of a thousand pages, or through two packs of cards, both of which would be absolutely opaque to the most brilliant ordinary light. Aluminum, tin, and glass of the same thickness are all transparent, but they keep out a portion of the rays; whereas platinum and lead are quite opaque. To these rays aluminum is two hundred times as transparent as platinum. Wood, carbon, leather, and slate are much more transparent to the X-rays than is glass, some kinds of glass being almost opaque, tho quite transparent to ordinary light.—WALLACE *The Wonderful Century,* ch. 5, p. 39. (D. M. & Co., 1899.)

3656. VISION, REMARKABLE ADJUSTMENTS FOR—*The Eye Surpasses the Camera.*—As an optical instrument, the eye is superior to the camera in the following, among many other particulars, which may be enumerated in detail: 1. The correctness of images even in a large field of view. 2. The simplicity and efficiency of the means by which chromatic aberration is avoided. 3. The perfect efficiency of its adaptation to different distances. In the photographic camera it is well known that only a comparatively small object can be accurately focused. In the photograph of a large object near at hand the upper and lower limits are always more or less hazy, and vertical lines appear curved. This is due to the fact that the image produced by a convex lens is really slightly curved and can only be received without distortion on a slightly curved concave screen, hence the distortion on a flat surface of ground glass. It is different with the eye, since it possesses a concave background, upon which the field of vision is depicted, and with which the curved form of the image coincides exactly. Thus the defect of the camera obscura is entirely avoided, for the eye is able to embrace a large field of vision, the margins of which are depicted distinctly and without distortion. If the retina had a plane surface like the ground-glass plate in a camera, it must necessarily be much larger than is really the case if we were to see as much; moreover, the central portion of the field of vision alone would give a good, clear picture.—BERNSTEIN, quoted by BAKER in *Handbook of Physiology,* vol. ii, ch. 19, p. 213. (W. W., 1885.)

3657. VISIONS, DREADFUL, IN ALCOHOLIC MANIA—*Reptiles and Specters Seen—Delirium Tremens.*—This state [delirium tremens], which constitutes a connecting link between intoxication and insanity, seems rather to arise from perverted and imperfect nutrition of the brain than from poisoning of the blood; for it may be produced by other agencies which depress the nervous power, such as great loss of blood, the shock of severe injuries, or extreme cold. It is characterized by a low, restless activity of the cerebrum, manifesting itself in muttering delirium, with occasional paroxysms of greater violence; and the nature of this delirium almost always shows the mind of the subject of it to be possessed with the apprehension of some direful calamity. He imagines his bed to be covered with loathsome reptiles; he sees the walls of his apartment covered with foul or terrific specters; and he supposes the friends or attendants who stand around to be fiends come to drag him down into a fiery abyss beneath. Here we have, as in the case of false perceptions, . . . a misinterpretation of actual sense-impressions, under the influence of a dominant emotional state.—CARPENTER *Mental Physiology,* bk. ii, ch. 17, p. 656. (A., 1900.)

3658. VISIONS OF SCIENCE—*Conscious of Its Own Incompleteness—Hopeful of Mastery.*—From what has been said, it will be seen that tho a considerable amount of knowledge has been obtained respecting bacteria in the soil, it may be conjectured that actually there is still a great deal to ascertain before the microbiology of soil is in any measure complete or even intelligent. The mere mention of tetanus and typhoid in the soil, and their habits, nutriment, and products therein, not to mention the work of the economic bacteria, is to open up to the scientific mind a vast realm of possibility. It is scarcely too much to say that a fuller knowledge of the part which soil plays in the culture and propagation of bacteria may suffice to revolutionize the practise of preventive medicine. Truly, our knowledge at the moment is rather a heterogeneous collection of isolated facts and theories, some of which, at all events, require ample confirmation; still, there is a basis for the future which promises much constructive work.—NEWMAN *Bacteria,* ch. 5, p. 177. (G. P. P., 1899.)

3659. VISITORS FROM THE STARS —*The Lenarto Meteor under Chemical Analysis—Must Have Come from a Star Whose Atmosphere Is Dense with Hydrogen—Comets Originally Expelled from Sun or Star.*—Professor Graham, the late Master of the Mint, and one of the greatest chemists of our day, examined the iron of an aerolite, called the Lenarto meteor from the place where it fell. He tested it with special reference to the quantity of hydrogen contained in it; for hydrogen and other gases can be occluded, as it is called, or, as it were, closed in within the substance of iron. Now observe what he says about the iron of this meteor: "It has been found difficult to impregnate malleable iron with more than an equal volume of hydrogen under the pressure of our atmosphere. Now, the meteoric iron (this Lenarto iron is remarkably pure and malleable) gave up about three times that amount without being fully exhausted. The inference is that the meteorite *had been extruded from a dense atmosphere of hydrogen gas,* for which we must look beyond the light cometary matter floating about within the limits of our solar system. . . . Hydrogen has been recognized by the spectrum analysis of the light of the fixed stars by Messrs. Huggins and Miller. The same gas constitutes, according to the wide researches of Father Secchi, the principal element of a numerous class of stars, of which Alpha Lyræ (the leading brilliant of the Lyre) is the type. The iron of Lenarto has no doubt come from such an atmosphere, in which hydrogen greatly prevailed. *This meteorite may be looked upon as holding imprisoned within it, and bearing to us, the hydrogen of the stars.*"

We are led, then, to the startling conclusion that comets (for what applies to the meteoric trains must needs apply to the comets whence those trains proceed) have been expelled either from our sun or from one or other of the stars.—PROCTOR *Expanse of Heaven*, p. 146. (L. G. & Co., 1897.)

3660. VISITS OF CEREMONY AMONG BIRDS—*The South-American Lapwing.*—If a person watches any two birds [South-American lapwings] for some time—for they live in pairs—he will see another lapwing, one of a neighboring couple, rise up and fly to them, leaving his own mate to guard their chosen ground; and instead of resenting this visit as an unwarranted intrusion on their domain, as they would certainly resent the approach of almost any other bird, they welcome it with notes and signs of pleasure. Advancing to the visitor, they place themselves behind it; then all three, keeping step, begin a rapid march, uttering resonant, drumming notes in time with their movements, the notes of the pair behind being emitted in a stream, like a drum-roll, while the leader utters loud single notes at regular intervals. The march ceases; the leader elevates his wings and stands erect and motionless, still uttering loud notes, while the other two, with puffed-out plumage and standing exactly abreast, stoop forward and downward until the tips of their beaks touch the ground, and, sinking their rhythmical voices to a murmur, remain for some time in this posture. The performance is then over and the visitor goes back to his own ground and mate, to receive a visitor himself later on.—HUDSON *Naturalist in La Plata*, ch. 19, p. 269. (C. & H., 1895.)

3661. VITALITY, ENDURING, OF TYPHOID BACILLUS IN SOIL—*Frost and Snow Powerless to Destroy.*—Dr. Robertson [has made] admirable researches into the growth of the bacillus of typhoid in soil. By experimental inoculation of soil with broth cultures he was able to isolate the bacillus twelve months after, alive and virulent. He concludes that the typhoid organism is capable of growing very rapidly in certain soils, and under certain circumstances can survive from one summer to another. The rains of spring and autumn or the frosts and snows of winter do not kill them off so long as there is sufficient organic pabulum. Sunlight, the bactericidal power of which is well known, had, as would be expected, no effect except upon the bacteria directly exposed to its rays. The *bacillus typhosus* quickly dies out in the soil of grass-covered areas. Dr. Robertson holds that the chief channel of infection between typhoid-infected soil and man is dust. As in tubercle and anthrax, so in typhoid, dried dust or excreta containing the bacillus is the vehicle of disease.—NEWMAN *Bacteria*, ch. 5, p. 176. (G. P. P., 1899.)

3662. VITALITY LOWERED—*Gives Foothold to Disease—Effect of Sewer-gas.*—Tho not of material importance as regards bacterial treatment of sewage, this subject calls for some remark. For long it has been known that air polluted by sewage emanations is capable of giving rise to various degrees of ill health. These chiefly affect two parts of the body: one is the throat, and the other is the alimentary canal. Irritation and inflammation may be set up in both by sewer-air. Such conditions are in all probability produced by a lowering of the resistance and vitality of the tissues, and not by either a conveyance of bacteria in sewer-air or any stimulating effect upon bacteria exercised by sewer-air. What evidence we have is against such factors.—NEWMAN *Bacteria*, ch. 2, p. 87. (G. P. P., 1899.)

3663. VIVIDNESS OF MEMORY SUGGESTS NEARNESS IN TIME—*A Corrective in Recalling Intervening Events.*—Sometimes pictures of very remote incidents may suddenly present themselves to our minds with a singular degree of brightness and force. And when this is the case there is a disposition to think of them as near. If

the relations of the event to other events preceding and succeeding it are not remembered, this momentary illusion will persist. We have all heard persons exclaim, "It seems only yesterday," under the sense of nearness which accompanies a recollection of a remote event when vividly excited. The most familiar instance of such lively reproduction is the feeling which we experience on revisiting the scene of some memorable event. At such a time the past may return with something of the insistence of a present perceived reality.—SULLY *Illusions*, ch. 10, p. 257. (A., 1897.)

3664. VOID, SENSE OF, FROM LACK OF CUSTOMARY SOUND—*Facts in Consciousness, but Unheeded.*—When we first come out of a mill or factory, in which we have remained long enough to get wonted to the noise, we feel as if something were lacking. Our total feeling of existence is different from what it was when we were in the mill. . . . A friend writes to me: "I have in my room a little clock which does not run quite twenty-four hours without winding. In consequence of this, it often stops. So soon as this happens I notice it, whereas I naturally fail to notice it when going. When this first began to happen there was this modification: I suddenly felt an undefined uneasiness or sort of void, without being able to say what was the matter; and only after some consideration did I find the cause in the stopping of the clock.—C. E. MÜLLER, quoted by JAMES in *Psychology*, vol. i, ch. 11, p. 456. (H. H. & Co., 1899.)

3665. VOLCANO AND EARTHQUAKE IN CONJUNCTION—It is a very general opinion that earthquakes and volcanoes have a common origin; for both are confined to certain regions, altho the subterranean movements are least violent in the immediate proximity of volcanic vents, especially where the discharge of aeriform fluids and melted rock is made constantly from the same crater.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 245. (A., 1854.)

3666. ———— *Shock and Eruption Simultaneous.*—One of the earliest records of a severe earthquake and a volcanic eruption occurring simultaneously is found in the accounts of the destruction of Herculaneum and Pompeii. The throwing-up of Monte Nuovo in the neighborhood of Pozzuoli was accompanied with a dreadful earthquake. At the time of the eruptions of Kilauea in 1789 the ground shook and rocked so that persons could not stand. The first eruption of the volcano Irasu, in Costa Rica (1783), was accompanied by violent earthquakes. The smoke and flames which are said to have issued from the side of Mount Fojo at the time of the Lisbon earthquake are regarded by some as having been volcanic. Others thought that the phenomena, rather than being on the side of Fojo, which showed no traces of volcanic action, had taken place in the ocean. At the time of the great earthquake at Concepcion (1835), whilst the waves were coming in, two great submarine eruptions were observed. One, behind the isle of Quiriquina, appeared like a column of smoke. The other, in the bay of San Vicente, appeared to form a whirlpool. The sea-water became black, and had a sulfurous smell, there being a vast eruption of gas in bubbles. Many fish were killed. With this same earthquake, near to Juan Fernandez, about one mile from the shore, the sea appeared to boil, and a high column of smoke was thrown into the air. At night flames were seen.

In 1861, when Mendoza was destroyed and 10,000 inhabitants killed, a volcano at the foot of which Mendoza is situated burst into eruption.—MILNE *Earthquakes*, ch. 16, p. 274. (A., 1899.)

3667. VOLCANO, PROBLEMS OF THE—*A Fiery Flood—Waves Hardened into Rock.*—The lava-streams of active volcanoes, those last stragglers of the preceding powerful product of volcanic action, still contain unsolved problems for geology and mineralogy. We behold the lava breaking forth from the crater, and the mass of fire congealing into stone. Biased by the prevailing error that we understand what is being formed before our eyes, we suppose that we understand the formation of the lava rock. But, in fact, we are still far from such insight. The lava flowing almost without sound from the crevices, in a tough, heavy stream, already contains completely formed crystals. It gradually congeals, carrying flakes like a stream of ice. The quiet flow of the lava at its egress is in peculiar contrast to the racket and noise the stream makes in its progress and near to its end. Finally it becomes a wild aggregate, a procession of hills of glowing blocks of rock, propelled and rolled forward by an invisible hand. It is not a simple consolidation of homogeneous masses; steam and gases are active meanwhile, chemical processes are taking place. The glowing fire gradually disappears, but while the mass solidifies and crystallizes heat is again liberated, and the chemical processes may long continue after everything upon the surface of the mighty stream may be rigid and seemingly dead.—RATH *Der Vesuv, eine geologische Skizze*, in *Virchow und Holtzendorff's Sammlung gemeinverständlicher wissenschaftlicher Vorträge (Serie viii*, p. 671). (Translated for *Scientific Side-Lights.)*

3668. VOLCANO, QUIESCENT—*Delusive Repose—A Century of Quiet—Sudden Eruption.*—For nearly a century after the birth of Monte Nuovo, Vesuvius continued in a state of tranquillity. There had been no violent eruption for 492 years, and it appears that the crater was then exactly in the condition of the present extinct volcano of Astroni, near Naples. Bracini, who

visited Vesuvius not long before the eruption of 1631, gives the following interesting description of the interior: "The crater was five miles in circumference, and about a thousand paces deep; its sides were covered with brushwood, and at the bottom there was a plain on which cattle grazed. In the woody parts wild boars frequently harbored. In one part of the plain, covered with ashes, were three small pools, one filled with hot and bitter water, another salter than the sea, and a third hot, but tasteless." But at length these forests and grassy plains were consumed, being suddenly blown into the air, and their ashes scattered to the winds. In December, 1631, seven streams of lava poured at once from the crater, and overflowed several villages, on the flanks and at the foot of the mountain. Resina, partly built over the ancient site of Herculaneum, was consumed by the fiery torrent. Great floods of mud were as destructive as the lava itself—no uncommon occurrence during these catastrophes; for such is the violence of rains produced by the evolutions of aqueous vapor that torrents of water descend the cone, and becoming charged with impalpable volcanic dust, and rolling along loose ashes, acquire sufficient consistency to deserve their ordinary appellation of "aqueous lavas."—LYELL *Principles of Geology*, bk. ii, ch. 23, p. 374. (A., 1854.)

3669. VOLCANO RENDERS SERVICE TO MAN—*Buildings Cemented with Mortar from Depths of the Earth.*—The quantity of rain which falls during volcanic eruptions is often enormous, owing to the condensation of the great volumes of steam emitted from the vent. Consequently the falling lapilli and dust often descend upon the mountain, not in a dry state, but in the condition of a muddy paste. Many volcanic mountains have evidently been built up by the flow of successive masses of such muddy paste over their surfaces. Some volcanic materials when mixed with water have the property of rapidly "setting" like concrete. The ancient Romans and modern Italians, well acquainted with this property of certain kinds of volcanic dust and lapilli, have in all ages employed this "puzzolana," as it is called, as mortar for building.—JUDD *Volcanoes*, ch. 4, p. 89. (A., 1899.)

3670. VOLCANO TURNS FRUITFUL LAND INTO BARRENNESS—*Irredeemable Sterility of Lava-stream.*—In the year 1302 [occurred the eruption] of a lava-stream from a new vent on the southeast end of the island of Ischia. During part of 1301 earthquakes had succeeded one another with fearful rapidity; and they terminated at last with the discharge of a lava-stream from a point named the Campo del Arso, not far from the town of Ischia. This lava ran quite down to the sea—a distance of about two miles; in color it varies from iron-gray to reddish black, and is remarkable for the glassy feldspar which it contains. Its surface is almost as sterile, after a period of five centuries, as if it had cooled down yesterday. A few scantlings of wild thyme, and two or three other dwarfish plants, alone appear in the interstices of the scoriæ, while the Vesuvian lava of 1767 is already covered with a luxuriant vegetation. Pontanus, whose country-house was burnt and overwhelmed, describes the dreadful scene as having lasted two months. Many houses were swallowed up, and a partial emigration of the inhabitants followed.—LYELL *Principles of Geology*, bk. ii, ch. 22, p. 365. (A., 1854.)

3671. VOLCANOES EARTH'S SAFETY-VALVES—*Rocks Crumpled Like Tissue-paper by Internal Forces.*—No one who has not studied the crushed, crumpled, fractured, and altered condition of many of the sedimentary rocks of the globe can form the faintest idea of the enormous effects of the internal forces which have been in operation within the earth's crust during earlier geological periods. And it is only by such studies as these that we at last learn to regard the earthquake and volcanic phenomena of our globe, not as the grandest and most important effects of these forces, but as their secondary and accidental accompaniments. "Volcanoes," it has been said, "are the safety-valves of the globe"; and when we come to realize the real extent and nature of the internal forces ceaselessly working in the earth's crust we shall scarcely be disposed to regard the simile as an overstrained one.—JUDD *Volcanoes*, ch. 10, p. 289. (A., 1899.)

3672. VOLCANOES IN MINIATURE—*Imprisoned Steam Escaping from Sulfur.*—In the process of extracting sulfur from the residues obtained during the manufacture of soda, some very interesting phenomena are manifested. The molten sulfur is exposed to a temperature of 262° F. and a pressure of two or three atmospheres, in the presence of steam; under these circumstances it is found that the sulfur absorbs a considerable quantity of water, which is given off again with great violence from the mass as it undergoes solidification. The hardened crust which forms on the surface of the molten sulfur is agitated and fissured, miniature cones and lava-streams being formed upon it, which have a striking resemblance to the grander phenomena of the same kind exhibited upon the crust of the globe.—JUDD *Volcanoes*, ch. 12, p. 356. (A., 1899.)

3673. VOLCANOES, PRESENT NUMBER OF—*Seeming Quiescence Often Delusive.*—What is the number of volcanoes which are still vomiting forth lava during the present period of the earth's vitality? It is difficult to ascertain, for often mountains have seemed for a long time to be extinct; forests have grown up in their disused craters, and their beds of lava have been covered up under a rich carpet of vegetation,

when suddenly the sleeping force beneath is aroused and some fresh volcanic outlet is opened through the ground. When Vesuvius woke up from its protracted slumber, to swallow up Pompeii and the other towns lying round its base, it had rested for some centuries, and the Romans looked upon it as nothing but a lifeless mountain like the peaks of the Apennines. On the other hand, it is very possible that some craters from which steam and jets of gas are still escaping, or which have thrown out lava during the historic era, have entered decisively into a period of repose, ceasing somehow to maintain their communication with the subterranean center of molten matter. The number of vents which serve for the eruption of lava can therefore be ascertained in a merely approximate way. Humboldt enumerates 223 active volcanoes; Keith Johnson arrives at the larger number of 270 . . . ; but this latter estimate is probably too small.—RECLUS *The Earth*, pt. iv, ch. 62, p. 432. (H., 1871.)

3674. VOLITION A FORCE—*Will Draws on Latent Supplies in the Body—Application and Direction of Energy.*—Is there nothing in the human body to liberate it from that chain of necessity which the law of conservation coils around inorganic nature? Look at two men upon a mountainside, with apparently equal physical strength; the one will sink and fail, while the other scales the summit. Has not volition, in this case, a creative power? Physically considered, the law that rules the operations of a steam-engine rules the operations of the climber. For every pound raised by the former, an equivalent quantity of its heat disappears; and for every step the climber ascends an amount of heat, equivalent jointly to his own weight and the height to which it is raised, is lost to his body. The strong will can draw largely upon the physical energy furnished by the food; but it can create nothing. The function of the will is to apply and direct, not to create.—TYNDALL *Heat a Mode of Motion*, lect. 17, p. 531. (A., 1900.)

3675. VOLITION AS ESSENTIAL TO LIFE AS AUTOMATISM—*Man Has His Own Part to Play—Voluntary and Involuntary Processes Blend in Perfect Living.*—We find that in maintaining this natural life Nature has a share and man has a share. By far the larger part is done for us—the breathing, the secreting, the circulating of the blood, the building up of the organism. And altho the part which man plays is a minor part, yet, strange to say, it is not less essential to the well-being, and even to the being, of the whole. For instance, man has to take food. He has nothing to do with it after he has once taken it, for the moment it passes his lips it is taken in hand by reflex actions and handed on from one organ to another, his control over it, in the natural course of things, being completely lost. But the initial act was his. And without that nothing could have been done. Now whether there be an exact analogy between the voluntary and involuntary functions in the body and the corresponding processes in the soul we do not at present inquire. But this will indicate, at least, that man has his own part to play.—DRUMMOND *Natural Law in the Spiritual World*, essay 7, p. 228. (H. Al.)

3676. VOLITION INCARNATED IN THE BODY—*Habitual Voluntary Movements Become Automatic—The Motor Memory.*—Each time a voluntary action is performed, an impulse is discharged by the will to the muscles. . . . The mind being concerned with the execution of the movement, and not with the individual muscles, the further elaboration of the impulse is brought about by the ganglion cells of the motor memory centers.

Each time the higher faculties send impulses to several of these governing cells at once, an association is formed between them, resulting in a permanent modification of their constituent protoplasm. By repetition of the same movement, this association of the cells becomes stronger and stronger, until a very slight stimulus is required to bring about the movement.

It is this modification of their protoplasm and association of the cells which constitutes the motor memory. The motor memory thus bears the same relation to the outgoing impulses of the mind as the sensory memory does to the ingoing impressions. The motor memory has, therefore, only to do with voluntary movements, or movements which have been primarily voluntary, but have become secondarily reflex.—ELDRIDGE-GREEN *Memory and Its Cultivation*, pt. i, ch. 4, p. 25. (A., 1900.)

3677. VOLITION WEAKENED BY HASHISH—*Control and Coordination of Thought Lost.*—One of the first appreciable effects of the hashish is the gradual weakening of that power of volitionally controlling and directing the thoughts, which is so characteristic of the vigorous mind. The individual feels himself incapable of fixing his attention upon any subject; the continuity of his thoughts being continually drawn off by a succession of disconnected ideas, which force themselves (as it were) into his mind, without his being able in the least to trace their origin. These speedily engross his attention, and present themselves in strange combinations, so as to produce the most impossible and fantastic creations. By a strong effort of the will, however, the original thread of the ideas may still be recovered, and the interlopers may be driven away; their remembrance, however, being preserved, like that of a dream recalling events long since past. These lucid intervals become progressively of shorter dura-

tion, and can be less frequently procured by a voluntary effort.—CARPENTER *Mental Physiology,* bk. ii, ch. 17, p. 640. (A., 1900).

3678. VOYAGERS, AERIAL, UNSEEN—*Gossamer-spiders in Multitudes Floating through the Air.*—The gossamer-spider, most spiritual of living things, of which there are numerous species, some extremely beautiful in coloring and markings, is the most numerous of our spiders. Only when the declining sun flings a broad track of shiny silver light on the plain does one get some faint conception of the unnumbered millions of these buoyant little creatures busy weaving their gauzy veil over the earth and floating unseen, like an ethereal vital dust, in the atmosphere.—HUDSON *Naturalist in La Plata,* ch. 14, p. 184. (C. & H., 1895.)

3679. VOYAGERS, INVOLUNTARY—*Bees on Mountain Summit—Butterflies on Ship in South Sea.*—To the surprise of the adventurous travelers the summit of Fremont's Peak was found to be visited by bees. It is probable that these insects, like the butterflies which I found at far higher elevations in the chain of the Andes, and also within the limits of perpetual snow, had been involuntarily drawn thither by ascending currents of air. I have even seen large-winged lepidoptera, which had been carried far out to sea by land-winds, drop on the ship's deck at a considerable distance from land in the South Sea.—HUMBOLDT *Views of Nature,* p. 33. (Bell, 1896.)

3680. ——— ——— *Organisms Borne by Fallen Tree to Distant Lands.*—It is well known, from numerous examples, how far in many cases trunks of trees, hard-shelled fruits, and other not readily perishable portions of plants are carried away from their original home by the course of rivers and by the currents of the sea. Trunks of palm-trees from the West Indies are brought by the Gulf Stream to the British and Norwegian coasts. All large rivers bring down driftwood from the mountains, and frequently Alpine plants are carried from their home at the source of the river into the plains, and even further, down to the sea. Frequently numerous creatures live between the roots of the plants thus carried down; and between the branches of the trees thus washed away there are various inhabitants which have to take part in the passive migration. The bark of the tree is covered with mosses, lichens, and parasitic insects. Other insects, spiders, etc., even small reptiles and mammals, are hidden within the hollow trunk or cling to the branches. In the earth adhering to the fibers of the roots, in the dust lying in the cracks of the bark, there are innumerable germs of smaller animals and plants. Now, if the trunk thus washed away lands safely on a foreign shore or on a distant island, the guests who had to take part in the involuntary voyage can leave their boat and settle in the new country.—HAECKEL *History of Creation,* vol. i, ch. 14, p. 372. (K. P. & Co., 1899.)

3681. VOYAGES, TOO ADVENTUROUS—*Butterflies at Sea—Frail Creatures the Sport of the Elements.*—Several times when the ship has been some miles off the mouth of the Plata, and at other times when off the shores of Northern Patagonia, we have been surrounded by insects. One evening, when we were about ten miles from the Bay of San Blas, vast numbers of butterflies, in bands or flocks of countless myriads, extended as far as the eye could range. Even by the aid of a telescope it was not possible to see a space free from butterflies. The seamen cried out "it was snowing butterflies," and such in fact was the appearance. . . . The day had been fine and calm, and the one previous to it equally so, with light and variable airs. Hence we cannot suppose that the insects were blown off the land, but we must conclude that they voluntarily took flight. . . . Before sunset a strong breeze sprung up from the north, and this must have caused tens of thousands of the butterflies and other insects to have perished.—DARWIN *Naturalist's Voyage around the World,* ch. 8, p. 160. (A., 1898.)

3682. WAKEFULNESS PARTIAL AND CONTROLLED—*Mother Hears the Stirring of Her Babe—Does the Mind Sleep?*—The mother who is asleep to every sound but the stirrings of her babe evidently has the babe-portion of her auditory sensibility systematically awake. Relatively to that, the rest of her mind is in a state of systematized anesthesia. That department, split off and disconnected from the sleeping part, can none the less wake the latter up in case of need. So that on the whole the quarrel between Descartes and Locke as to whether the mind ever sleeps is less near to solution than ever. On a priori speculative grounds Locke's view that thought and feeling may at times wholly disappear seems the more plausible. As glands cease to secrete and muscles to contract, so the brain should sometimes cease to carry currents, and with this minimum of its activity might well coexist a minimum of consciousness. On the other hand, we see how deceptive are appearances, and are forced to admit that a part of consciousness may sever its connections with other parts and yet continue to be. On the whole it is best to abstain from a conclusion. The science of the near future will doubtless answer this question more wisely than we can now.—JAMES *Psychology,* vol. i, ch. 8, p. 213. (H. H. & Co., 1899.)

3683. WALKING AN INSTINCTIVE MOVEMENT—*Impulse Suddenly Developed in Human Beings.*—The walking instinct may awaken with [remarkable] suddenness, and its entire education be completed within a week's compass, barring, of course, a little "grogginess" in the gait. Individual in-

fants vary enormously; but on the whole it is safe to say that the mode of development of these locomotor instincts is inconsistent with the account given by the older English associationist school, of their being results of the individual's education. . . . [Persons] who have observed new-born calves, lambs, and pigs agree that in these animals the powers of standing and walking, and of interpreting the topographical significance of sights and sounds, are all but fully developed at birth. Often in animals who seem to be "learning" to walk or fly the semblance is illusive. The awkwardness shown is not due to the fact that "experience" has not yet been there to associate the successful movements and exclude the failures, but to the fact that the animal is beginning his attempts before the coordinating centers have quite ripened for their work.—JAMES *Psychology*, vol. ii, ch. 24, p. 405. (H. H. & Co., 1899.)

3684. WALKING SCIENTIFICALLY DESCRIBED—Walking is a continual falling forward.—KAAT *Leonardo da Vinci als Naturforscher.* (Translated for *Scientific Side-Lights.)*

3685. WANDERERS OF ANCIENT DAYS—*Boulders Carried Far by Ice—Northern Rocks on Western Prairies.*—The mineralogical character of the loose materials forming the American drift leaves no doubt that the whole movement [of the ancient glaciers], with the exception of a few local modifications easily accounted for by the lay of the land, was from north to south, all the fragments not belonging to the localities where they occur being readily traced to rocks *in situ* to the north of their present resting-places. The farther one journeys from their origin the more extraordinary does the presence of these boulders become. It strikes one strangely to find even in New England fragments of rock from the shores of Lake Superior; but it is still more impressive to meet with masses of northern rock on the prairies of Illinois or Iowa. One may follow these boulders to the fortieth degree of latitude, beyond which they become more and more rare, while the finer drift alone extends farther south.—AGASSIZ *Geological Sketches*, ser. ii, p. 84. (H. M. & Co., 1896.)

3686. WAR AMONG INSECTS—*Slave-making Ants Terrible in Battle—Prowess and Excellence Not Coextensive.*—*Polyergus rufescens*, the celebrated slave-making or Amazon-ant, has a mode of combat almost peculiar to herself. The jaws are very powerful, and pointed. If attacked—if, for instance, another ant seizes her by a leg—she at once takes her enemy's head into her jaws, which generally makes her quit her hold. If she does not, the *Polyergus* closes her mandibles, so that the points pierce the brain of her enemy, paralyzing the nervous system. The victim falls in convulsions, setting free her terrible foe. In this manner a comparatively small force of *Polyergus* will fearlessly attack much larger armies of other species, and suffer themselves scarcely any loss.—AVEBURY *Ants, Bees, and Wasps*, ch. 1, p. 18. (A., 1900.)

3687. WAR, FOREIGN MERCENARIES NO LONGER EMPLOYED IN—*Modern Standing Armies.*—Looking at the army system as it is in our modern world, one favorable change is to be noticed. The employment of foreign mercenary troops, which almost through the whole stretch of historical record has been a national evil alike in war and peace, is at last dying out. It is not so with the system of standing armies which drain the life and wealth of the world on a scale more enormous even than in past times, and stand as the great obstacle to harmony between nations. The student of politics can but hope that in time the pressure of vast armies kept on a war-footing may prove unbearable to the European nations which maintain them, and that the time may come when the standing army may shrink to a nucleus ready for the exigencies of actual war if it shall arise, while serving in peace-time as a branch of the national police.—TYLOR *Anthropology*, ch. 9, p. 228. (A., 1899.)

3688. WAR, THE FOLLY OF—*Relative Insignificance of the Earth in the Universe.*—Behold a little globe whirling in the infinite void. Round this globule vegetate 1,450 millions of so-called reasonable beings —or rather talkers—who know not whence they come nor whither they go, each of them, moreover, born to die very soon; and this poor humanity has resolved the problem, not of living happily in the light of Nature, but of suffering constantly both in body and mind. It does not emerge from its native ignorance, it does not rise to the intellectual pleasures of art and science, and torments itself perpetually with chimerical ambitions. Strange social organization! This race is divided into tribes subject to chiefs, and from time to time we see these tribes, afflicted with furious folly, arrayed against each other, obeying the signal of a handful of sanguinary evil-doers who live at their expense, and the infamous hydra of war mows down its victims, who fall like ripe ears of corn on the blood-stained fields. Forty millions of men are killed regularly every century in order to maintain the microscopical divisions of a little globule into several ant-hills.—FLAMMARION *Popular Astronomy*, bk. i, ch. 1, p. 12. (A.)

3689. WARFARE IN NATURE—*Animals Constructed for Others' Destruction.*—Very many animals contribute naturally to the destruction of caterpillars, spiders, and other insects. They lay their eggs in living caterpillars, which consequently become diseased and die either before or after their change into pupæ. Many also confine themselves to other species of their own genus, in whose bodies they lay their eggs,

so that, as Rolander has remarked of certain species, some appear to be created solely for the destruction of others.—BLUMENBACH *Manual of the Elements of Natural History*, p. 217.

3690. WASPS PROVIDING FOR THEIR OFFSPRING—*Prevision among Insects.*—The females of certain species of this genus *(Sphex)* dig a hole in sandy ground, drag a large spider, or the caterpillar of a *Phalœna*, into it, lame it by biting off its legs, and then lay an egg in each hole, so that the larva may suck the spinning-fluid from the animal the mother has buried, and by this means prepare for itself a habitation in which to pass through its metamorphosis. —BLUMENBACH *Manual of the Elements of Natural History*, p. 217.

3691. WASTE OF EARTH'S SURFACE REPAIRED—*Perpetual Reconstruction—A Necessity Early Discerned—Geology in the Eighteenth Century.*—Generelli [an Italian monk and philosopher, 1749] then describes the continual waste of mountains and continents by the action of rivers and torrents, and concludes with these eloquent and original observations: "Is it possible that this waste should have continued for six thousand and perhaps a greater number of years, and that the mountains should remain so great, unless their ruins have been repaired? Is it credible that the Author of Nature should have founded the world upon such laws as that the dry land should forever be growing smaller, and at last become wholly submerged beneath the waters? Is it credible that, amid so many created things, the mountains alone should daily diminish in number and bulk, without there being any repair of their losses? This would be contrary to that order of Providence which is seen to reign in all other things in the universe. Wherefore I deem it just to conclude that the same cause which, in the beginning of time, raised mountains from the abyss, has down to the present day continued to produce others, in order to restore from time to time the losses of all such as sink down in different places, or are rent asunder, or in other ways suffer disintegration. If this be admitted, we can easily understand why there should now be found upon many mountains so great a number of crustaceans and other marine animals."—LYELL *Principles of Geology*, bk. i, ch. 3, p. 37. (A., 1854.)

3692. WASTE OF THE EARTH'S CAPITAL—*Sewage and Garbage Thrown into the Sea—Stock of Fixed Nitrogen Finite.*—Sir William Crookes has recently pointed out the vast importance of using all the available nitrogen in the service of wheat production. The distillation of coal in the process of gas-making yields a certain amount of its nitrogen in the form of sulfate of ammonia, and this, like other nitrogenous manures, might be used to give back to the soil some of the nitrogen drained from it. But such manuring cannot keep pace, according to Sir W. Crookes, with the present loss of fixed nitrogen from the soil. We have already referred to several ways in which "loss" of nitrogen occurs. To these may well be added the enormous loss occurring in the waste of sewage when it is passed into the sea. . . . Let us remember that the plant creates nothing in this direction; there is nothing in wheat which is not absorbed from the soil, and unless the abstracted nitrogen is returned to the soil its fertility must be ultimately exhausted. When we apply to the land sodium nitrate, sulfate of ammonia, guano, and similar manurial substances, we are drawing on the earth's capital, and our drafts will not be perpetually responded to.—NEWMAN *Bacteria*, ch. 5, p. 160. (G. P. P., 1899.)

3693. WASTE, SEEMING, IN NATURE—*But One Seed among Thousands Grows—Progeny of One Orchid Would Cover the Earth.*—I was curious to estimate the number of seeds produced by some few orchids, so I took a ripe capsule of *Cephalanthera grandiflora*, and arranged the seeds on a long ruled line as equably as I could in a narrow hillock; and then counted the seeds in an accurately measured length of one-tenth of an inch. In this way the contents of the capsule were estimated at 6,020 seeds, and very few of these were bad; the four capsules borne by the same plant would have therefore contained 24,080 seeds. Estimating in the same manner the smaller seeds of *Orchis maculata*, I found the number nearly the same, viz., 6,200; and, as I have often seen above thirty capsules on the same plant, the total amount would be 186,300. As this orchid is perennial, and cannot in most places be increasing in number, one seed alone of this large number yields a mature plant once in every few years.*

To give an idea what the above figures really mean, I will briefly show the possible rate of increase of *O. maculata:* an acre of land would hold 174,240 plants, each having a space of six inches square, and this would be just sufficient for their growth; so that, making the fair allowance of 400 bad seeds in each capsule, an acre would be thickly clothed by the progeny of a single plant. At the same rate of increase the grandchildren would cover a space slightly exceeding the island of Anglesea; and the great grandchildren of a single plant would nearly (in the ratio of 47 to 50) clothe with one uniform green carpet the entire surface of the land throughout the globe. But the number of seeds produced by one of our common British orchids is as nothing compared to that of some of the exotic kinds.—DARWIN *Fertilization of Orchids*, ch. 9, p. 277. (A., 1898.)

* "And finding that of *fifty* seeds
She often brings but *one* to bear."
—TENNYSON *In Memoriam*, st. lv, ll. 11-12.

The poet's estimate is cautious and conservative, beside the studious computation of the man of science.

3694. ——— ——— *Seeds—Animals—Man.*—Altho astronomy, bringing us as it does in presence of the infinities of space, and indicating the operations of an infinity of force acting during infinite time, is of all others the science which seems to present to us the most striking instances of waste in Nature, it would yet be easy to cite many instances of seeming waste without leaving the teachings of our earth. How many seeds are scattered over the face of the earth to no visible purpose, for each one that falls on good ground and grows to perfection? How many creatures are brought to life that perish before they reach maturity? This, true of all races of animals, is true of man. True of the individual man, it is also true of nations, of races of men. History shows us, and we see in our own day, whole tribes of men disappearing without having reached that degree of civilization which we may regard as the measure of maturity in races and nations.—PROCTOR *Our Place among Infinities*, p. 40. (L. G. & Co., 1897.)

3695. ——— ——— *Sun's Heat Poured through Empty Space.*—Our earth receives less than the 2,000 millionth part of the heat and light emitted by the sun; all the planets together receive less than the 230 millionth part; the rest is seemingly scattered uselessly through the interstellar depths. To other worlds, circling around other suns, our sun may indeed appear as a star; but how minute the quantity of light and heat so received from him compared with the enormous quantity apparently wasted. The portion which seems squandered is scarcely affected at all by such small uses; and that portion is more than 230 millions of times as great as the portion used to warm and illuminate the solar system. And then consider what is the actual amount of energy thus seemingly wasted. I have computed (adopting Sir J. Herschel's estimate of the amount of heat poured by the sun upon each square mile of the earth's surface) that the sun emits in each second as much heat as would result from the burning of 11,600,000,000,000,000 tons of coal, and of this enormous amount of energy the portion utilized (that is, the heat received by the various members of the solar system) corresponds only to that due to the consumption of about 50 millions of tons—only 50 millions out of 11,600 millions of millions.—PROCTOR *Our Place among Infinities*, p. 42. (L. G. & Co., 1897.)

3696. WASTING OF THE MOUNTAINS—*Atmospheric Erosion of the Matterhorn.*—Standing on the *arête*, at the foot of a remarkable cliff gable seen from Zermatt, and permitting the vision to range over the Matterhorn, its appearance is exceedingly wild and impressive. Hardly two things can be more different than the two aspects of the mountain from above and below. Seen from the Riffel, or Zermatt, it presents itself as a compact pyramid, smooth and steep, and defiant of the weathering air. From above it seems torn to pieces by the frosts of ages, while its vast facets are so foreshortened as to stretch out into the distance like plains. But this underestimate of the steepness of the mountain is checked by the deportment of its stones. Their discharge along the side of the pyramid to-day was incessant, and at any moment, by detaching a single boulder, we could let loose a cataract of them, which flew with wild rapidity and with a thunderous clatter down the mountain. We once wandered too far from the *arête*, and were warned back to it by a train of these missiles sweeping past us.—TYNDALL *Hours of Exercise in the Alps*, ch. 24, p. 290. (A., 1898.)

3697. WATCHFULNESS OF MARMOTS—*Sociability in Hibernation.*—The European marmots of the Alps, we learn from Professor Blasius, "live high up in the snowy regions of the mountains, generally preferring exposed cliffs, whence they may have a clear view of any approaching danger, for which, while quietly basking in the sun, or actively running about in search of food, a constant watch is kept. When one of them raises the cry of warning, a loud piercing whistle well known to travelers in the Alps, they all instantly take to flight, and hide themselves in holes and crannies among the rocks, often not reappearing at the entrance of their hiding-place until several hours have elapsed, and then frequently standing motionless on the lookout for a still longer period. Their food consists of the roots and leaves of various Alpine plants, which, like squirrels, they lift to their mouths with their fore paws. For their winter quarters they make a large, round burrow, with but one entrance, and ending in a sleeping-place thickly lined with hay. Here from ten to fifteen marmots will often pass the winter, all lying closely packed together, fast asleep, until the spring."—MIVART *Types of Animal Life*, ch. 12, p. 353. (L. B. & Co., 1893.)

3698. WATER AN EXCEPTION TO LAW OF EXPANSION—*A Warning against Hasty Generalizations.*—A most valuable lesson as to the allowance we ought always to make for the unknown "possibilities of Nature" is taught us by an exceptional phenomenon so familiar that it does not attract the notice it has a right to claim. Next to the law of the universal attraction of masses of matter, there is none that seems to have a wider range than that of the expansion of bodies by heat and their contraction by cold. Excluding water and one or two other substances, the fact of such expansion might be said to be invariable; and, as regards bodies whose gaseous condition is known, the law of expansion can be stated in a form no less simple and definite than the law of gravitation. Supposing those exceptions, then, to be unknown, the law would be universal

in its range. But it comes to be discovered that water, whilst conforming to it in its expansion from 39½° upwards to its boiling-point, as also, when it passes into steam, to the special law of expansion of vapors, is exceptional in expanding also from 39½° downwards to its freezing-point; and of this failure in the universality of the law no rationale can be given.—CARPENTER *Nature and Man*, lect. 6, p. 207. (A., 1889.)

3699. WATER A POOR CONDUCTOR OF HEAT—*Solid Matter Hinders Diffusion.*—Count Rumford made a number of very amusing but also very important experiments on the diffusion of heat through liquids. He had frequently noticed to his cost the tenacity with which stewed apples retained their heat. "I never burned my mouth with them," he says, "without endeavoring, but in vain, to find out some way of accounting for this most surprising phenomenon." He noticed that the water of the volcanic bay of Baiæ was cold, while the sand on which the water lay was intolerably hot a few inches beneath the surface. Hence he concluded that water could not possess the power of conducting heat with which it was credited in his day. A sunbeam falling on a flask of heated alcohol, which he had placed in a window to cool, revealed to him, by the motion of floating particles, the convection currents of the liquid. His final inference was that it is solely by such currents that liquids distribute their heat, and that if these currents are impeded a proportionate retardation of the diffusion occurs. The fibrous part of apples he found to amount to only two per cent. of the whole, the rest being mainly water. Still this small modicum of solid matter so reduced the power of transferring heat that, while a thermometer surrounded by stewed apples required 535 seconds to be raised 80° F. in temperature, it required, when surrounded by water, only 172 seconds. Mixing 192 grains of starch with 2,276 grains of water, he found the convection so hampered by the starch that the heating of his thermometer 80° required 341 seconds of exposure, while when surrounded by pure water only 172 seconds were needed. The retention of heat by thick soup or chocolate is to be referred to the cause revealed by these experiments of Rumford.—TYNDALL *Heat a Mode of Motion*, lect. 8, p. 216. (A., 1900.)

3700. WATER A PROTECTION TO PLANTS—*Leaf-cups Stop Injurious Insects.*—In aquatic plants, of course, the access of ants is precluded by the isolation in water. Nay, even many land plants have secured to themselves the same advantage, the leaves forming a cup round the stem. Some species have such a leaf-cup at each joint; in others there is only a single basin, formed by the rosette of radical leaves. In these receptacles rain and dew not only collect, but are retained for a considerable time. In our own country *Dipsacus sylvestris* (the common teazel) is the best marked instance of this mode of protection, tho it is possible that these cups serve another purpose, and form, as suggested by Francis Darwin, traps in which insects are caught, and in which they are dissolved by the contained fluid, so as to serve as food for the plant. However this may be, the basins are generally found to contain water, even if no rain has fallen for some days, and must, therefore, serve to prevent the access of ants.—AVEBURY *Ants, Bees, and Wasps*, ch. 3, p. 52. (A., 1900.)

3701. WATER AS A MECHANICAL POWER—*The World's Progress Dependent on Water-power.*—If we were permitted to coin a word, we should call all the arts combined that relate to the getting, preserving, and utilizing of water, hydrotechny; but that would furnish rather a long term for the study of these arts—hydrotechnology—tho it is not lacking in euphony. The spring, the well, the city reservoir and water-works; the open stream, the canal, the locomotive; the tide-wheel, the overshot, the turbine—all of these indicate progress in hydrotechny as related to aliment, to transportation, to irrigation, and to manufactures. The world's progress has followed the water, and water has never been absent from men's minds.—MASON *Aboriginal American Mechanics* (*Memoirs of the International Congress of Anthropology*, p. 82). (Sch. P. C.)

3702. WATER CHANGING LEVEL—*Work Done on the Way—Energy of Position.*—An instance of energy of position may be found in a body of water having a level higher than that of the ocean's surface. If this body of water is released it will flow down to the lower level, and during its progress it is able to do work, such as grinding grain, sawing wood, or driving the machinery of a factory. When it has reached its lowest level it no longer possesses the power to do work. In order to restore to it the same power that it had at the higher level we should have to expend the same amount of energy in pumping it back that it gave up when it ran down. As a matter of fact we should have to expend a great deal more, because of the great amount of energy that would be lost in the form of friction in the machinery employed for the purpose.—ELISHA GRAY *Nature's Miracles*, vol. ii, ch. 2, p. 19. (F. H. & H., 1900.)

3703. WATER, COLOR OF, DUE TO FINELY DIVIDED MATTER—Absolutely pure water, like pure air, is colorless, but all seas and lakes, however clear and translucent, contain abundance of very finely divided matter, organic or inorganic, which, as in the atmosphere, reflects the blue rays in such quantity as to overpower the white or colored light reflected from the fewer and more rapidly sinking particles of larger size.—WALLACE *The Wonderful Century*, ch. 9, p. 75. (D. M. & Co., 1899.)

3704. WATER EXPANDS IN FREEZING—*Protection to Life in Lakes and Streams.* —"It does not appear to me," he [Count Rumford] writes, "that there is anything which human sagacity can fathom, within the wide-extended bounds of the visible creation, which affords a more striking or more palpable proof of the wisdom of the Creator, and of the special care he has taken in the general arrangement of the universe to preserve animal life, than this wonderful contrivance." Rumford's enthusiasm was excited by considerations like the following: Suppose a lake exposed to a clear, wintry sky. The superficial water is first chilled; it contracts, becomes heavier, and sinks by its superior weight, its place being taken by the lighter water from below. In time this is chilled and sinks in its turn. Thus a circulation is established, the cold, dense water descending, and the lighter and warmer water rising to the top. Supposing this to continue, even after the first pellicles of ice have been formed at the surface; the ice would sink, and the process would not cease until the entire water of the lake would be solidified. Death to every living thing in the water would be the consequence. But just when matters become critical, Nature, speaking poetically, steps aside from her ordinary proceeding, causes the water to expand by cooling, and the cold water to swim like a scum on the surface. Solidification ensues, but the solid is much lighter than the adjacent liquid, and the ice forms a protecting roof over the living things below.—TYNDALL *Heat a Mode of Motion*, lect. 4, p. 109. (A., 1900.)

3705. WATER HONEYCOMBS ROCKS FAR UNDER GROUND—*How Mineral Springs Are Formed.*—In the case of feldspathic rocks, it is found that some of the constituent minerals, more especially the feldspars, usually show traces of decomposition at depths of many feet or even yards below the weathered superficial portions. It is hard, indeed, to get a specimen of any such rock from the bottom of our deepest quarries which is perfectly fresh. Water soaks through interstitial fissures and pores, and finds its way by joints and other division-planes, so that chemical action, with resultant rock-decay, is carried on at the greatest depths to which water can penetrate. This underground water eventually comes to the surface again through similar joints, etc., opening upwards, and thus forms natural springs. All these springs contain mineral matter, derived from the chemical decomposition and solution of rock-constituents. Many, indeed, are so highly impregnated, that as soon as they are exposed to evaporation they begin to deposit some of their mineral matter. Thus vast quantities of rock-material are brought up from the bowels of the earth.—GEIKIE *Earth Sculpture*, ch. 2, p. 30. (G. P. P., 1898.)

3706. WATER IN MOUNTAIN LAKES UNFROZEN—*Uniform Temperature in the Depths.*—The temperature observations made in Lake Tahoe . . . furnish an illustration of the fact that deep lakes, even when situated at a high elevation and subject to low winter temperatures, do not freeze. The surface waters are cooled in winter and descend, while warmer waters from below rise and take their place, thus establishing a circulation; but the body of water is so great that its entire mass never becomes cooled sufficiently during the comparatively short winters to check the upward circulation and allow ice to form. At the greatest depth reached the temperature was 39.2° F., which is the temperature of fresh water at its maximum density; and from more extended observation in other lakes, the water is believed to retain this temperature throughout the year.—RUSSELL *Lakes of North America*, ch. 4, p. 64. (G. & Co., 1895.)

3707. WATER STORED IN THORNY PLANT—*A Reservoir for Thirsty Animals—Provision in Lower Organism for Needs of Higher—Cactus in South America.*—The cactus form . . . is almost peculiar to the new continent; it is sometimes globular, sometimes articulated, sometimes rising in tall, polygonal columns not unlike organ-pipes. This group forms the most striking contrast with the lily and banana families, and belongs to that class of plants which Bernardin de St. Pierre felicitously terms vegetable fountains of the desert. In the parched, arid plains of South America the thirsting animals eagerly seek the *Melocactus*, a globular plant half-buried in the dry sand, whose succulent interior is concealed by formidable prickles. The stems of the columnar cactus attain a height of more than 30 feet; their candelabra-like ramifications, frequently covered with lichens, reminding the traveler, by some analogy in their physiognomy, of certain of the African euphorbias.—HUMBOLDT *Views of Nature*, p. 220. (Bell, 1896.)

3708. WATER, TRANSLUCENCE OF—*Rich Color of Waves that Break in Foam.*—Nothing can be more superb than the green of the Atlantic waves when the circumstances are favorable to the exhibition of the color. As long as a wave remains unbroken no color appears, but when the foam just doubles over the crest like an Alpine snow-cornice, under the cornice we often see a display of the most exquisite green. It is metallic in its brilliancy. But foam is necessary to its production. The foam is first illuminated, and it scatters the light in all directions; the light which passes through the higher portion of the wave alone reaches the eye, and gives to that portion its matchless color. The folding of the wave, producing, as it does, a series of longitudinal protuberances and furrows, which

act like cylindrical lenses, introduces variations in the intensity of the light, and materially enhances its beauty.—TYNDALL *Lectures on Light*, lect. 1, p. 36. (A., 1898.)

3709. WATER, WONDERFUL TRANSFORMATION OF—*Feathery Lightness of Snow.*—We are all familiar with the way in which the flakes, in falling, are driven about by the slightest breath of air, and every one knows, likewise, that a handful of snow is perhaps as light a handful as one can lift. The actual weight of snow depends very much upon circumstances. Snow varies greatly in compactness, but on an average it is found that a cubic yard of this substance weighs about 187 lbs., or about one-twelfth of an equal bulk of water. Ice itself is lighter than water, but in nothing like the same proportion; and a certain volume of snow would, on an average, have only about one-eleventh of the weight of an equal volume of ice. No one will be at a loss to understand the reason for it; it is so manifest that snow in the mass consists of innumerable little spicules of ice interlaced together, and having a great quantity of air enclosed in the meshes, that the lightness of this substance when compared with ice or water will not excite any surprise.—CHISHOLM *Nature-Studies*, p. 29. (Hum., 1888.)

3710. WATERS CROWDED UPON WATERS—*The Whirlpool Rapids at Niagara —Illustration of Wave-action.*—The most impressive illustration of the action of waves on waves that I have ever seen occurs near Niagara. For a distance of two miles, or thereabouts, below the Falls, the river Niagara flows unruffled through its excavated gorge. The bed subsequently narrows, and the water quickens its motion. At the place called the "Whirlpool Rapids" I estimated the width of the river at 300 feet, an estimate confirmed by the dwellers on the spot. When it is remembered that the drainage of nearly half a continent is compressed into this space, the impetuosity of the river's escape through this gorge may be imagined. Two kinds of motion are here obviously active, a motion of translation and a motion of undulation—the race of the river through its gorge, and the great waves generated by its collision with the obstacles in its way. In the middle of the stream the rush and tossing are most violent; at all events, the impetuous force of the individual waves is here most strikingly displayed. Vast pyramidal heaps leap incessantly from the river, some of them with such energy as to jerk their summits into the air, where they hang suspended as bundles of liquid pearls, which, when shone upon by the sun, are of indescribable beauty.—TYNDALL *Lectures on Light*, lect. 2, p. 56. (A., 1898.)

3711. WATERS TRANSPORTING SEEDS—*Wind and Wave Combine to Plant the Sedge in New Locations.*—The most abundant plants in marshes and by pond-sides are the sedges. They resemble coarse grasses, for which they are frequently mistaken. Some of them have seeds adapted to wind-dispersal by means of cottony tufts of hairs; but most of them simply cast their seeds upon the quiet waters, where they float upon the surface and are driven along by every breath of wind. It will be worth your while to remove some "seed" of sedge from a ripened head and study its structure. As you pick up what appears to be the seed . . . you notice how little weight it has. On looking closer you are likely to see that it is triangular, in many species being shaped like a miniature beechnut. If you press upon it the "seed" breaks, and you find it apparently hollow on the inside. But if you look carefully you will see within a tiny body, which is really the seed. The other is simply an air-filled boat in which the seed remains. A seed with such an outer covering is called an achene, altho in most achenes there is not the air space which these sedges show. Now drop some of these sedge achenes upon the surface of water in a tumbler or other vessel. Do they sink? See them rest buoyantly upon the top, with one flat side down and the two other sides projecting upward. Blow gently across the water; see how quickly the tiny sails catch the breeze and the achenes move away. Fancy them upon a quiet pool out-of-doors: the wind ripples the surface and away they go to the other side, where they may find lodgment, or, perchance, if the pool has an outlet, they may be carried far away by the running water.—WEED *Seed Travelers*, pt. i, p. 26. (G. & Co., 1899.)

3712. WAVE-MOTION IS THE ADVANCE OF A FORM—*The Particles of Water Merely Rise and Fall.*—In the earliest writings of the ancients we find the notion that sound is conveyed by the air. Aristotle gives expression to this notion, and the great architect, Vitruvius, compares the waves of sound to waves of water. But the real mechanism of wave-motion was hidden from the ancients, and indeed was not made clear until the time of Newton. The central difficulty of the subject was to distinguish between the motion of the wave itself and the motion of the particles which at any moment constitute the wave.

Stand upon the seashore and observe the advancing rollers before they are distorted by the friction of the bottom. Every wave has a back and a front, and, if you clearly seize the image of the moving wave, you will see that every particle of water along the front of the wave is in the act of rising, while every particle along its back is in the act of sinking. The particles in front reach in succession the crest of the wave, and as soon as the crest is passed they begin to fall. They then reach the furrow or sinus of the wave, and can sink no farther. Immediately afterwards they become the front

of the succeeding wave, rise again until they reach the crest, and then sink as before. Thus, while the waves pass onward horizontally, the individual particles are simply lifted up and down vertically. Observe a sea-fowl, or, if you are a swimmer, abandon yourself to the action of the waves; you are not carried forward, but simply rocked up and down. The propagation of a wave is the propagation of a form, and not the transference of the substance which constitutes the wave.—TYNDALL *Lectures on Light*, lect. 2, p. 52. (A., 1898.)

3713. WAVES HEAVING EARTH'S CRUST IN EARTHQUAKE—*Trees Lashing Ground with Their Branches.*—The whole of the country over which the effects of the great shocks [of the Calabrian earthquake] extended was at times heaved simultaneously, like an angry sea, and sensations resembling seasickness were experienced by many of the inhabitants. Those who have watched the sky from the deck of a sea-tossed ship will have noticed that the drifting clouds seem at times to be arrested in their motion; it is in reality the ship which is moving for the moment in the same direction as the clouds, and thus neutralizes the effects of their motion. The same phenomenon was observed during the Calabrian earthquake; and nothing serves to give us a stronger impression of the turbulence of those internal heavings which make the dry land as unstable as the billows of a swelling sea. Trees whose roots continued firmly embedded in the soil were seen to lash the ground with their branches.—PROCTOR *Notes on Earthquakes*, p. 3. (Hum., 1887.)

3714. WAVES, INTERFERENCE OF—*The Whirlpool at Niagara—Motion Doubled or Annulled.*—The first impression, and, indeed, the current explanation of these rapids [of Niagara] is, that the central bed of the river is cumbered with large boulders, and that the jostling, tossing, and wild leaping of the water there are due to its impact against these obstacles. A very different explanation occurred to me upon the spot. Boulders derived from the adjacent cliffs visibly cumber the sides of the river. Against these the water rises and sinks rhythmically, but violently, large waves being thus produced. On the generation of each wave there is an immediate compounding of the wave-motion with the river-motion. The ridges, which in still water would proceed in circular curves round the center of disturbance, cross the river obliquely, and the result is that at the center waves commingle which have really been generated at the sides. This crossing of waves may be seen on a small scale in any gutter after rain; it may also be seen on simply pouring water from a wide-lipped jug. Where crest and furrow cross each other the wave is annulled; where furrow and furrow cross, the river is plowed to a greater depth; and where crest and crest aid each other we have that astonishing leap of the water which breaks the cohesion of the crests, and tosses them shattered into the air. The phenomena observed at the Whirlpool Rapids constitute, in fact, one of the grandest illustrations of the principle of interference.—TYNDALL *Lectures on Light*, lect. 2, p. 57. (A., 1898.)

3715. WAVES OF HEAT LIKE WAVES OF LIGHT—*Ethereal Billows Beat on Human Body.*—To the eye of the philosopher, looking at such matters without reference to sensation, these obscure radiations [of heat] are substantially the same in kind as those which produce the impression of light. You must, therefore, figure the molecules of the heated body as in a state of motion; you must figure that motion as communicated to the surrounding ether, and transmitted through it with a velocity which we have the strongest reason for believing to be the same as that of light. When, therefore, you turn towards a fire on a cold day and expose your chilled hands to its influence, the warmth which you feel is due to the impact of these ethereal billows upon your skin. They throw the nerves into motion, and the consciousness, corresponding to this motion, is what we popularly call warmth.—TYNDALL *Heat a Mode of Motion*, lect. 10, p. 276. (A., 1900.)

3716. WAVES OF LIGHT MORE RAPID AS HEAT MORE INTENSE—*Wire Passes from Red to White.*—A platinum wire [through which an electric current flows] is warmed by the current, and may be felt to be warm by the hand. It emits waves of heat, but no light. Augmenting the strength of the current, the wire becomes hotter; it finally glows with a sober red light. At this point Dr. Draper many years ago began an interesting investigation. He employed a voltaic current to heat his platinum, and he studied, by means of a prism, the successive introduction of the colors of the spectrum. His first color . . . was red; then came orange, then yellow, then green, and lastly all the shades of blue. Thus as the temperature of the platinum was gradually augmented, the atoms were caused to vibrate more rapidly; shorter waves were thus introduced, until finally waves were obtained corresponding to the entire spectrum.—TYNDALL *Lectures on Light*, lect. 5, p. 174. (A., 1898.)

3717. WAVES OF SEA AND LAND IN EARTHQUAKE—*Undulations Transmitted through Solid Bodies.*—Mr. Mallet, in his memoir [1846] . . . has endeavored to bring to bear on this difficult subject [of earthquake shocks] the more advanced knowledge obtained of late years respecting the true theory of waves. He conceives that when the origin of the shock is beneath the deep ocean one wave is propagated through the land, and another moving with inferior velocity is formed on the surface of the ocean. This last rolls in upon the

land long after the earth wave has arrived and spent itself. However irreconcilable it may be to our common notions of solid bodies, to imagine them capable of transmitting, with such extreme velocity, motions analogous to tidal waves, it seems nevertheless certain that such undulations are produced, and it is supposed that when the shock passes a given point each particle of the solid earth describes an ellipse in space. The facility with which all the particles of a solid mass can be made to vibrate may be illustrated, says Gay-Lussac, by many familiar examples. If we apply the ear to one end of a long wooden beam, and listen attentively when the other end is struck by a pin's head, we hear the shock distinctly, which shows that every fiber throughout the whole length has been made to vibrate. The rattling of carriages on the pavement shakes the largest edifices; and in the quarries underneath some quarters in Paris it is found that the movement is communicated through a considerable thickness of rock.—LYELL *Principles of Geology*, bk. ii, ch. 29, p. 498. (A., 1854.)

3718. WEALTH OF CELESTIAL BEAUTY—*The Stars Repeat the Lesson of the Lilies (Matt. vi, 28-29).*—I conceive that few thoughts can be more striking and instructive than those suggested by this infinite wealth of beauty and variety [among the double stars and the star-clusters of the sky]. We see throughout the whole universe the same splendor on a large scale which is bestowed on a small scale upon the flowers of the field, which "toil not, neither do they spin, yet Solomon in all his glory was not arrayed like one of these."—PROCTOR *Expanse of Heaven*, p. 237. (L. G. & Co., 1897.)

3719. WEAPON AND TOOL—*Knife or Dagger.*—Among implements used by man, the same forms may sometimes be employed for destruction and at other times for industrial purposes. When used for destruction they are weapons, but when their function is industrial they are tools. The same object, when used as a weapon, becomes a dagger, but if it be employed as an edged tool it is a knife. As in the case of all other weapons or tools, the edged tool works by pressure, by friction, or by a blow. One used by means of a blow is an ax if the edge is in a line with the handle, and an adz if it lies across the handle; an edged tool working by friction is a scraper, but one working by pressure is a knife.—MASON *The Man's Knife among the North American Indians (Report of the U. S. National Museum for 1897*, p. 727).

3720. WEAPONS IMPROVISED—*Armadillo Saws Snake with Its Shell.*—A friend of mine, a careful observer, who was engaged in cattle-breeding amongst the stony sierras near Cape Corrientes, described to me an encounter he witnessed between an armadillo and a poisonous snake. While seated on the hillside one day he observed a snake, about twenty inches in length, lying coiled up on a stone five or six yards beneath him. By and by, a hairy armadillo appeared trotting directly towards it. Apparently the snake perceived and feared its approach, for it quickly uncoiled itself and began gliding away. Instantly the armadillo rushed on to it, and squatting close down, began swaying its body backward and forward with a regular sawing motion, thus lacerating its victim with the sharp, deep-cut edges of its bony covering. The snake struggled to free itself, biting savagely at its aggressor, for its head and neck were disengaged. Its bites made no impression, and very soon it dropped its head, and when its enemy drew off it was dead and very much mangled.—HUDSON *Naturalist in La Plata*, ch. 4, p. 72. (C. & H., 1895.)

3721. WEAPONS, POISONED, IN ANCIENT TIMES—*Reprobation of the Custom in Homer—Its Prevalence in Middle Ages—Also among Modern Savages.*—The daubing on of venom to make them [offensive weapons] more deadly is found among low tribes far over the world. Thus the bushman mixes serpent's poison with the euphorbia juice, and the South-American native poison-maker, prepared by a long fast for the mysterious act, concocts the paralyzing urari, or curare, in the secret depths of the forest, where no woman's eye may fall on the fearful process. Poisoned arrows were known to the ancient world, as witness the lines which tell of Odysseus going to Ephyra for the man-slaying drug to smear his bronze-tipped arrows; but Ilos would not give it, for he feared the ever-living gods. Thus it seems that in early ages the moral sense of the higher nations had already condemned the poisoned weapons of the savage with something of the horror Europeans now feel in examining the Italian bravo's daggers of the Middle Ages, with their poison-grooves imitated from the serpent's tooth. —TYLOR *Anthropology*, ch. 9, p. 221. (A., 1899.)

3722. WEAVING INVENTED BY PRIMITIVE WOMEN—*Styles Transported over the World.*—There is no work of woman's fingers that furnishes a better opportunity for the study of techno-geography, or the relationship existing between an industry and the region where it may have been developed, than the textile art. Suppose a certain kind of raw material to abound in any area or country: you may be sure that savage women searched it out and developed it in their crude way. Furthermore, the peculiar qualities and idiosyncrasies of each substance suggest and demand a certain treatment. Women of the lowest grades of culture have not been slow in discovering this; so that between them and the natural product there has been a kind of understanding or co-

operation leading to local styles. If these women were moved far away, they carried oftentimes these processes with them, and plied the old trade upon such strange materials as they discovered in their new home. —MASON *Woman's Share in Primitive Culture,* ch. 3, p. 41. (A., 1894.)

3723. WEAVING OF THE SPIDER —*Fluid Silk Hardening by Exposure to the Air.*—Like the silk-moth's caterpillar, or the mussel in the sea, which are also spinners and weavers, Madame Spider's silk-secretion exists within her body in a fluid state. It is made and secreted by certain silk-forming glands which end in the "spinnerets." These last are conical projections placed near the tail; and comparative anatomy seems to teach us that the spinnerets really represent much-altered limbs. Each of these organs seems in its essential nature to be composed of a multitude of fine tubes, opening at the top of the spinneret. This, then, is the apparatus wherewith our spider weaves.

Let us see how the weaving is carried on. The silk, while within the glands, exists in a semifluid state; but when it is exposed to the air it becomes dried, or of a more tenacious consistency, and in this state is susceptible of being drawn out into a fine thread. Think for a moment what happens to melted wax or glue. So long as the heat is of sufficient amount either substance remains fluid; but if we draw a little out of the pot on a piece of stick, exposure to the air hardens the wax or glue, and with a little dexterity we can produce the melted substance into a fine thread. This represents accurately enough how and why the semifluid silk of the spider becomes a dry thread when it is pressed out through the fine tubes of the spinnerets. — WILSON *Glimpses of Nature,* ch. 6, p. 23. (Hum., 1892.)

3724. WEIGHT BALANCED AGAINST DISTURBING FORCE—*The Spider's Knowledge of Mechanics.*—Practical acquaintance with mechanical principles . . . is sometimes shown by spiders when they find that a widely spread web is not tightly enough stretched, and as a consequence is to an inconvenient extent swayed about by the wind. Under such circumstances these animals have been observed to suspend to their webs small stones or other heavy objects, the weight of which serves to steady the whole system. Gleditsch saw a spider so circumstanced let itself down to the ground by means of a thread, seize a small stone, remount, and fasten the stone to the lower part of its web, at a height sufficient to enable animals and men to walk beneath it. —ROMANES *Animal Intelligence,* ch. 6, p. 220. (A., 1899.)

3725. WEIGHT OF THE SUN—*Density One-fourth That of Earth—Mass Not Proportioned to Size.*—We now know that the sun's average distance from the earth is about 93,000,000 miles, and consequently that his diameter is about 865,000 miles. The sun has been weighed against the earth and found to contain a quantity of matter nearly 330,000 times as great, and comparing this with his enormous bulk, it appears that his mean density is only about one-fourth that of the earth, or one and a quarter times that of water—in other words, the mass of the sun is about one-fourth greater than that of a globe of water of the same size.—YOUNG *The Sun,* int., p. 7. (A., 1898.)

3726. WHEEL, THE, A PREHISTORIC INVENTION—*The Primitive Farm-cart—War-chariots with Spoke-wheels in Ancient Egypt—Railway Wheels and Axles Return to Primitive Type.*—The wheel-carriage, which is among the most important machines ever contrived by man, must have been invented in ages before history. To see what constructive skill the leading nations had already attained to in times we reckon as of high antiquity, it is worth while to examine closely the Egyptian war-chariots, with their neatly-fitted and firmly-tired spoke-wheels turning on their axles secured by linchpins, while the body, pole, and double harness show equal technical skill. In looking for some hint as to how wheel-carriages came to be invented, it is of little use to judge from such high skilled work as was turned out by these Egyptian chariot-builders, or by the Roman *carpentarii* or carriage-builders from whom our *carpenters* inherit their name. But as often happens, rude contrivances may be found which look as tho they belonged to the early stages of the invention. The *plaustrum* or farm-cart of the ancient world in its rudest form had for wheels two solid wooden drums near a foot thick, and made from a tree-trunk cut across, which drums or wheels did not turn on the axle, but were fixed to it; the axle was kept in place by wooden stops, or passed through rings at the bottom of the cart, and went round together with its pair of wheels, as children's toy carts are made. It is curious to notice how, under changed conditions, the builders of railway carriages have returned to this early construction. . . . In such countries as Portugal the old classic bullock-cart on this principle is still to be seen, and it has been reasonably guessed that such carts tell the story how wheel-carriages came to be invented.—TYLOR *Anthropology,* ch. 8, p. 198. (A., 1899.)

3727. WHEELS FOR VEHICLES UNKNOWN IN AMERICA BEFORE COLUMBUS—*The Fly-wheel for Spindles and Drills.* —There was nothing on the continent that could be compared to a wheel, either for carriage or for mechanical purposes, when Columbus discovered America. The fly-wheel was well known and widely distributed on spindles and drills, but there were no wheel-barrows, carts or carriages, no cranks, or windlasses, or capstans. But the Alaskan Indians, and perhaps others, used the parbuckle, which combines the roller and the

pulley in the same device. For hoisting logs, a rope was fastened to the tops of posts, passed down under a log in the ground, back over the top of the post, and down to the ground, where it was seized by men. —MASON *Aboriginal American Mechanics (Memoirs of the International Congress of Anthropology*, p. 76). (Sch. P. C.)

3728. WHIRLWIND AS OBSERVED BY FRANKLIN—*A Means of Seed-dispersal.* —Franklin tells us, in one of his letters, that he saw, in Maryland, a whirlwind which began by taking up the dust which lay in the road, in the form of a sugar-loaf, with the pointed end downwards, and soon after grew to the height of forty or fifty feet, being twenty or thirty in diameter. It advanced in a direction contrary to the wind; and altho the rotary motion of the column was surprisingly rapid, its onward progress was sufficiently slow to allow a man to keep pace with it on foot. Franklin followed it on horseback, accompanied by his son, for three-quarters of a mile, and saw it enter a wood, where it twisted and turned round large trees with surprising force. These were carried up in a spiral line, and were seen flying in the air, together with boughs and innumerable leaves, which, from their height, appeared reduced to the apparent size of flies. As this cause operates at different intervals of time throughout a great portion of the earth's surface, it may be the means of bearing not only plants, but insects, land testacea and their eggs, with many other species of animals, to points which they could never otherwise have reached, and from which they may then begin to propagate themselves again as from a new center.—LYELL *Principles of Geology*, bk. iii, ch. 37, p. 619. (A., 1854.)

3729. WILDERNESS, PLANTING OF THE—*Wind-wafted Seeds—The Tumbleweed.* —There is a very common weed found on waste ground and also in fields and gardens, which on good soil, with plenty of room and light, grows much in the shape of a globe with a diameter of two to three feet. It is called *Amaranthus albus* in the books, and is one of the most prominent of our tumbleweeds. It does not start in the spring from seed till the weather becomes pretty warm. The leaves are small and slender, the flowers very small, with no display, and surrounded by little rigid, sharp-pointed bracts. When ripe in autumn, the dry, incurved branches are quite stiff; the main stem near the ground easily snaps off and leaves the light ball at the mercy of the winds. Such a plant is especially at home on prairies or cleared fields, where there are few large obstructions and where the wind has free access.

The mother plant, now dead, toiled busily during the heat of summer and produced thousands of little seeds. The best portion of her substance went to produce these seeds, giving each a portion of rich food for a start in life, and wrapping each in a glossy black coat. Now she is ready to sacrifice the rest of her body to be tumbled about, broken in pieces, and scattered in every direction for the good of her precious progeny, most of whom will find new places, where they will stand a chance the next summer to grow into plants.—BEAL *Seed Dispersal*, ch. 5, p. 31. (G. & Co., 1898.)

3730. "WILFULNESS," SUPPOSED, IN CHILD—*A Misinterpretation—Perhaps a Lack of Volitional Control.*—Great mistakes are often made by parents and teachers, who . . . treat as wilfulness what is in reality just the contrary of will-fulness, being the direct result of the want of volitional control over the automatic activity of the brain. To punish a child for the want of obedience which it has not the power to render is to inflict an injury which may almost be said to be irreparable. . . . Nothing retards the acquirement of the power of directing the intellectual processes so much as the emotional disturbance which the feeling of injustice provokes. Hence the determination often expressed, to "break the will" of an obstinate child by punishment, is almost certain to strengthen these reactionary influences. Many a child is put into "durance vile" for not learning "the little busy bee," who simply cannot give its small mind to the task, whilst disturbed by stern commands and threats of yet severer punishment for a disobedience it cannot help; when a suggestion kindly and skilfully adapted to its automatic nature, by directing the turbid current of thought and feeling into a smoother channel, and guiding the activity which it does not attempt to oppose, shall bring about the desired result, to the surprise alike of the baffled teacher, the passionate pupil, and the perplexed bystanders.—CARPENTER *Mental Physiology*, ch. 3, p. 135. (A., 1900.)

3731. WILL AS DISTINCT FROM IMPERSONAL FORCE—*Mind Sees in Nature a Reflection of Itself.*—Whatever difficulty there may be in conceiving of a will not exercised by a visible person, it is a difficulty which cannot be evaded by arresting our conceptions at the point at which they have arrived in forming the idea of laws or forces. That idea is itself made up out of elements derived from our own consciousness of personality. This fact is seen by men who do not see the interpretation of it. They denounce as a superstition the idea of any personal will separable from the forces which work in Nature. They say that this idea is a mere projection of our own personality into the world beyond—the shadow of our own form cast upon the ground on which we look. And indeed this, in a sense, is true. It is perfectly true that the mind does recognize in Nature a reflection of itself. But if this be a deception, it is a deception which is not avoided by transferring the idea of personality to the abstract

idea of force, or by investing combinations of force with the attributes of mind.—ARGYLL *Reign of Law*, ch. 2, p. 73. (Burt.)

3732. WILL AS VIEWED BY THE PHYSIOLOGIST — *Volition Connected with Organic Changes—Loss of Power of Will in Mental Derangement.*—As physiologists, we have to deal with volition as a function of the supreme centers, following reflection, varying in quantity and quality as its cause varies, strengthened by education and exercise, enfeebled by disuse, decaying with decay of structure, and always needing for its outward expression the educated agency of the subordinate motor centers. We have to deal with will, not as a single undecomposable faculty unaffected by bodily conditions, but as a result of organic changes in the supreme centers, affected as certainly and seriously by disorder of them as our motor faculties are by disorder of their centers. Loss of power of will is one of the earliest and most characteristic symptoms of mental derangement; and whatever may have been thought in times past, we know well now that the loss is not the work of some unclean spirit that has laid its hands upon the will, but the direct effect of physical disease.—MAUDSLEY *Body and Mind*, lect. 1, p. 28. (A., 1898.)

3733. WILL CREATES NO FORCE—*Existing Bodily Energy Directed by Mind.*—As a physiologist, I most fully recognize the fact that the physical force exerted by the body of man is not generated *de novo* by his will, but is derived from the oxidation of the constituents of his food. But holding it as equally certain, because the fact is capable of verification by every one as often as he chooses to make the experiment, that, in the performance of every volitional movement, that physical force is put in action, directed, and controlled, by the individual personality or "ego," I deem it just as absurd and illogical to affirm that there is no place for a God in Nature, originating, directing, and controlling its forces by his will, as it would be to assert that there is no place in man's body for his conscious mind.—CARPENTER *Nature and Man*, lect. 12, p. 364. (A., 1889.)

3734. WILL, DETHRONEMENT OF, IN INTOXICATION—*Drunkard a Madman—Limits of Responsibility and Punishment.*—When the government of the will is completely overthrown, and the excited passions rage uncontrolled, the drunkard may be most truly said to be a madman, and is, like him, *at the time* completely irresponsible for his actions, since, even if some glimmering consciousness of their criminality should still remain, he has lost all power either of restraining his vehement impulses, or of withdrawing himself from their influence. His responsibility arises from his having knowingly and voluntarily given up the reins of reason and conscience, and subjected himself to the domination of his evil passions; so that his better nature loses its due supremacy, and he becomes the mere instrument of his insane impulses. It has been argued with considerable plausibility that a man ought not to be punished for any crime he may commit in a state of intoxication, since he is then in a state of "temporary insanity"; but that he should be punished as severely for having brought himself into that state. This would doubtless be the most *logical* mode of dealing with the criminal; but as it would require that *every* drunkard should be held guilty of a crime equal in gravity to murder, such punishment could obviously not be enforced.—CARPENTER *Mental Physiology*, ch. 17, p. 651. (A., 1900.)

3735. WILL FIXING ATTENTION ON DIVINE IDEAL—The highest exercise of the will is shown in those who are endowed with vigorous intellectual powers, and whose strong emotional nature gives force to all their tendencies to action, but who determinately fix their attention on the divine ideal, and steadily endeavor to shape their character and direct their conduct in accordance with it.—CARPENTER *Mental Physiology*, bk. i, ch. 9, p. 428. (A., 1900.)

3736. WILL FREE FROM COMPULSION—*Motives Do Not Destroy Freedom.*—It is true that our wills can never be free from motives, and in this sense can never be free from "law." But this is only saying that we can never be free from the relations preestablished between the structure of our minds and the system of things in which they are formed to move. From these, it is true, indeed, that we never can be free. But as a matter of fact, we know that these relations do not involve compulsion. It is from compulsion that our wills are free, and from nothing else; and for this freedom we have the only evidence we can ever have for any ultimate truth respecting the powers of mind—the evidence of consciousness—that is, the evidence of observation turned in upon ourselves.—ARGYLL *Reign of Law*, ch. 6, p. 182. (Burt.)

3737. WILL IN OPPOSITION TO REFLEX ACTION—*Darwin's Experiment—Self-preserving Act Uncontrollable.*—To prevent the reflex action of crying out when in pain, it is often sufficient firmly to clench the teeth or to grasp some object and hold it tight. When the feet are tickled we can, by an effort of will, prevent the reflex action of jerking them up. So, too, the involuntary closing of the eyes and starting, when a blow is aimed at the head, can be similarly restrained.

Darwin has mentioned an interesting example of the way in which, on the other hand, such an instinctive reflex act may override the strongest effort of the will. He placed his face close against the glass of the cobra's cage in the Reptile House at the Zoological Gardens, and tho, of course, thoroughly convinced of his perfect security,

could not by any effort of the will prevent himself from starting back when the snake struck with fury at the glass.—BAKER *Handbook of Physiology*, vol. ii, ch. 18, p. 101. (W. W., 1885.)

3738. WILL IS ULTIMATE—*Not To Be Translated into Simpler Terms.*—The transition from merely considering an object as possible to deciding or willing it to be real; the change from the fluctuating to the stable personal attitude concerning it; from the "don't care" state of mind to that in which "we mean business," is one of the most familiar things in life. We can partly enumerate its conditions; and we can partly trace its consequences, especially the momentous one that when the mental object is a movement of our own body it realizes itself outwardly when the mental change in question has occurred. But the change itself as a subjective phenomenon is something which we can translate into no simpler terms.—JAMES *Psychology*, vol. ii, ch. 26, p. 569. (H. H. & Co., 1899.)

3739. WILL MAY SHUT OUT EVIDENCE—*Refusal to Look through Telescope.*—In the discussion of a question of intellectual truth, the will has the power of keeping some considerations more or less completely out of view, whilst it increases the force of others by fixing the attention upon them. Another familiar proverb, that "there are none so blind as those that won't see," precisely expresses the way in which the will thus exerts its influence. For as the opponents of the Copernican system refused to look at the satellites of Jupiter through the telescope of Galileo, so there are too many who wilfully turn away the eyes of their minds from inconvenient truths, or refuse to get a gleam of sunshine into the dark chambers of their intellects, where they hide as sacred treasures the antiquated beliefs of past ages, the worthlessness of which would be at once apparent if the full light of day were permitted to shine in upon them. —CARPENTER *Nature and Man*, lect. 7, p. 231. (A., 1889.)

3740. WILL, WEAKNESS OF, COUNTERACTED—*Mozart Saved by Good Influence—Help of Father and of Wife Sustained Great Composer.*—Mozart certainly stands alone among musicians, and deserves to rank as a typical example of genius. Mozart, like Coleridge, was a man whose will was weak in proportion to the automatic activity of his mind; and it is probable that if he had not been under the guidance, in the first instance, of a judicious father, and afterwards of an excellent wife, to both of whom he had the good sense to submit himself, his career would have been comparatively inglorious. For his lively sensibility made him the sport of every kind of impulse, so that he could neither keep firm to a resolution, nor resist a temptation; and hence he would never of his own accord have subjected himself to the discipline which his father imposed upon him, and without which he could not have been anything else than a "musical prodigy"; nor would he have had the motive which his conjugal affection supplied, for the steady application that was required for the elaboration of his greatest works. Hence his life becomes a most interesting study to the psychologist, no less than to the musician.—CARPENTER *Mental Physiology*, ch. 6, p. 271. (A., 1900.)

3741. WIND CHANGES CONTOUR OF MOUNTAINS—*Cliffs Shaped by Viewless Air.*—When a strong wind is blowing during a volcanic outburst, the materials may be driven to one side of the vent, and accumulate there more rapidly than on the other. Thus lop-sided cones are formed, such as may frequently be observed in some volcanic districts. In areas where constant currents of air, like the trade-winds, prevail, all the scoria-cones of the district may thus be found to be unequally developed on opposite sides, being lowest on those from which the prevalent winds blow, and highest on the sides towards which these winds blow. —JUDD *Volcanoes*, ch. 4, p. 90. (A., 1899.)

3742. WIND SCATTERS SEEDS—*Samaras or "Keys" of Maple and Ash.*—There are many methods by which seeds have been adapted to dispersal by the wind. The degree of adaptation is greatly varied. With the fruits of many trees the seed-envelopes have been drawn out into thin plates, by means of which in a strong wind—when of course they are most likely to break away from the stem—they may be carried to a considerable distance before falling to the ground. Even then during high winds many of them will be picked up and carried farther.

The familiar fruits, or "keys," of maple and ash at once come to mind as examples of this kind of dispersal. It is to be noted that generally in such cases the seed has a decided advantage in starting at a point some distance from the ground. Its chances of going far afield are much greater than they would be if the seed was borne on a herbaceous plant only a foot or two high. —WEED *Seed Travellers*, pt. i, p. 13. (G. & Co., 1899.)

3743. WINDS OF THE UPPER AIR—*Direction Opposite to That of Surface Currents—Volcanic Ashes Shot into Upper Stream of Air.*—It is not by reasoning alone that we arrive at a knowledge of the existence of the upper atmospheric current, tho reasoning is sufficient to show that compensation must take place somehow—that a wind cannot blow in any direction without an equal displacement of air taking place in the opposite direction. But clouds are sometimes seen in the tropics, high in the atmosphere, moving in a direction opposed to that of the constant wind below. Could we discharge a light body with sufficient force to cause it to penetrate the lower cur-

rent, and reach the higher, the direction of the body's motion would give us that of the wind above. Human strength cannot perform this experiment, but it has nevertheless been made. Ashes have been shot through the lower current by volcanoes, and, from the places where they have subsequently fallen, the direction of the wind which carried them has been inferred. Professor Dove, who has so enriched the knowledge of the age by his researches in meteorology, cites the following instance: "On the night of April 30 explosions like those of heavy artillery were heard at Barbadoes, so that the garrison at Fort St. Anne remained all night under arms. On May 1, at daybreak, the eastern portion of the horizon appeared clear, while the rest of the firmament was covered by a black cloud, which soon extended to the east, quenched the light there, and at length produced a darkness so intense that the windows in the rooms could not be discerned. A shower of ashes descended. Whence came these ashes? From the direction of the wind we should infer that they came from the Azores; they came, however, from the volcano Morne Garou in St. Vincent, which lies about 100 miles west of Barbadoes. The ashes had been cast into the current of the upper trade."—TYNDALL *Heat a Mode of Motion*, lect. 8, p. 209. (A., 1900.)

3744. WINE, ADULTERATION OF—*Connoisseur Demands Impossible Transparency—Use and Effect of Mineral Acids—An Imperial Martyr.*—The wine-merchants are . . . the victims of their customers, who demand an amount of transparency that is simply impossible as a permanent condition of unsophisticated grape wine. To anybody who has any knowledge of the chemistry of wine nothing can be more ludicrous than the antics of the pretending connoisseur of wine who holds his glass up to the light, shuts one eye (even at the stage before double vision commences), and admires the brilliancy of the liquid, this very brilliancy being, in nineteen samples out of twenty, the evidence of adulteration, cookery, or sophistication of some kind. Genuine wine made from pure grape-juice without chemical manipulation is a liquid that is never reliably clear. . . . Partial precipitation, sufficient to produce opalescence, is continually taking place, and therefore the unnatural brilliancy demanded is obtained by substituting the natural and wholesome tartrate by salts of mineral acids, and even by the free mineral acid itself. At one time I deemed this latter adulteration impossible, but have been convinced by direct examination of samples of high-priced (mark this, not cheap) dry sherries that they contained free sulfuric and sulfurous acid. . . .

But what is the effect of such free mineral acid on the drinker of the wine? If he is in any degree predisposed to gout, rheuma-ti[illegible]tone, or any of the lithic-acid diseases, his life is sacrificed, with preceding tortures of the most horrible kind. It has been stated, and probably with truth, that the late Emperor Napoleon III. drank dry sherry, and was a martyr of this kind.—WILLIAMS *Chemistry of Cookery*, ch. 16, p. 274. (A., 1900.)

3745. ———— ———— *Sulfuric Replaces Tartaric Acid—A Clergyman's Costly Error.*—The brilliancy thus obtained [by fining with sulfate of lime] is not lost by age or variations of temperature, and the dry sherries thus cooked are preferred by English wine-drinkers.

The sulfate of potash which, by the action of sulfate of lime, is made to replace bitartrate, is so readily soluble that neither changes of temperature nor increase of alcohol, due to further fermentation, will throw it down; and thus the wine-maker and wine-merchant, without any guilty intent, and ignorant of what he is really doing, sophisticates the wine, alters its essential composition, and adds an impurity in doing what he supposes to be a mere clarification or removal of impurities. . . .

So far, the wine-merchant; but how about the consumer? Simply that the substitution of a mineral acid—the sulfuric for a vegetable acid (the tartaric)—supplies him with a precipitant of lithic acid in his own body; that is, provides him with the source of gout, rheumatism, gravel, stone, etc., with which English wine-drinkers are proverbially tortured.

I am the more urgent in propounding this view of the subject because I see plainly that not only the patients, but too commonly their medical advisers, do not understand it. When I was in the midst of these experiments I called upon a clerical neighbor, and found him in his study with his foot on a pillow, and groaning with gout. A decanter of pale, choice, very dry sherry was on the table. He poured out a glass for me and another for himself. I tasted it, and then perpetrated the unheard-of rudeness of denouncing the wine for which my host had paid so high a price. He knew a little chemistry, and I accordingly went home forthwith, brought back some chlorid of barium, added it to his choice sherry, and showed him a precipitate which made him shudder. He drank no more dry sherry, and has had no serious relapse of gout.—WILLIAMS *Chemistry of Cookery*, ch. 16, p. 278. (A., 1900.)

3746. WINGS OF FLYING-FISH REALLY FINS—*Different Organs with Similar Function.*—When we speak of the flight of birds, of insects, of fishes, of bats, etc., and designate their locomotive organs indiscriminately as wings, it is evident that the character of the motion, and not the special structure of the organs, has determined our nomenclature. We are influenced by the same consideration when we give the name of "fins" to the organs of all animals which

swim in the water, be they whales, turtles, fishes, crustaceans, or mollusks. It requires but a superficial acquaintance with the anatomy of the flying-fishes to perceive that their organs of flight are built upon exactly the same pattern as the pectoral fins of most fishes, and differ entirely from the wing of birds, as also from the wing of bats, the latter being in all essentials a paw, identical with the paw of ordinary quadrupeds, save the length of the fingers and the absence of nails on the longest of them. No wonder, then, that the flight of the flying-fishes should entirely differ from that of birds or bats.—AGASSIZ *Journey in Brazil*, ch. 2, app., p. 522. (H. M. & Co., 1896.)

3747. WISDOM TRANSCENDING HUMAN POWER TO ATTAIN—*Newton's Grand Humility.*—Why . . . should we hesitate to receive the evidence of a philosopher like Newton, who, after spending a long life in the investigation of Nature, and with a success unparalleled in the history of science, uttered this memorable sentiment shortly before his death: "I do not know what I may appear to the world; but to myself I seem to have been only like a boy playing on the seashore, and devoting myself now and then to finding a smoother pebble or a prettier shell than ordinary, while the great ocean of truth lay all undiscovered before me." I know this sentiment has been so many times repeated as to seem trite, but, coming from whom it does, it cannot be too often quoted. It is the testimony of the foremost master of science to its greatest and sublimest truth.

We can all recognize the marks of design in Nature, and when we add to this evidence of our senses the testimony of a man like Newton, who assures us that the more our powers are enlarged, and the wider our knowledge becomes, the grander and vaster the design will appear, until it surpasses all our powers of thought or imagination, we begin to feel the full depth of the truth. . . . If our minds are incapable of comprehending the plan, who could have been equal to the design? "Whence, then, cometh wisdom, and where is the place of understanding, seeing it is hid from the eyes of all living, and kept close from the fowls of the air? . . . God understandeth the way thereof, and he knoweth the place thereof. For he looketh to the ends of the earth, and seeth under the whole heaven, to make the weight for the winds . . . and a way for the lightning of the thunder. Then did he see it and declare it; he prepared it, yea, and searched it out. And unto man he said, Behold the fear of the Lord, that is wisdom, and to depart from evil is understanding" [Job xxviii, 20-28].—COOKE *Religion and Chemistry*, ch. 2, p. 66. (S., 1891.)

3748. WITCH-GRASS ON WINGS OF WIND—*Distribution of Seeds.*—One breezy October morning the neighboring fields presented the appearance of a fairies' carnival. A thousand tenuous will-o'-the-wisps were dancing and sailing and whirling in every direction. Now one alone with feathery grace would glide along, to join a moment later a host of airy sprites, and be wafted hither and thither by the erratic breath of the zephyr god. Here and there the paths of miniature cyclones could be traced by the movements of whirling circles, while in other places solid phalanxes moved steadily forward. The ranks of the revelers were constantly depleted through desertions to the eastward, to be quickly filled by new recruits from out the west.

With some difficulty I caught a few of these feathery sprites, and, holding them securely, started homeward. But a sudden gust of wind left me empty-handed, save for some tiny pieces of stems; the sprites, again at liberty, sailed away with mocking grace. I caught more, and, shielding them from the wind, got them safely indoors, where they proved to be the seed-heads of a grass commonly known as the "old-witch grass."—WEED *Seed Travellers*, pt. i, p. 18. (G. & Co., 1899.)

3749. WOMAN A POWER IN SAVAGE LIFE—*Cowardice Repressed by Fear of Woman's Scorn.*—It must not be supposed that in any state of civilization a man's conduct depends altogether on his own moral sense of right and wrong. Controlling forces of society are at work even among savages, only in more rudimentary ways than among ourselves. Public opinion is already a great power, and the way in which it acts is particularly to be noticed. . . . The assembled tribe can crush the mean and cowardly with their scorn, or give that reward of glory for which the high-spirited will risk goods and life. Travelers have remarked that the women, however downtrodden, know how to make their influence felt in this way, and many a warrior whose heart was failing him in face of the enemy has turned from flight when he thought of the girls' mockery when he should slink home to the village, safe but disgraced.—TYLOR *Anthropology*, ch. 16, p. 408. (A., 1899.)

3750. WOMAN DOMESTICATES THE CAT—*The Guardian of the Food Supply.*—The world has to thank woman for the domestication of the cat. There may be some dispute as to who has the honor of subduing the dog and the milk- and fleece-yielding animals. But woman tamed the wildcat for the protection of her granaries. Of the time when this heartless beast laid down its arms and enlisted in her service no one knoweth. Already at the dawn of written history in Egypt the cat was sacred to Sekhet, or Pasht, daughter of Ra and wife of Ptah. Then as now the cat and the goddess had among their other qualifications the faculty of seeing in the dark. Her method of domestication was to secure the young wildcats and rear them about her household as play-

things for her children, and to gratify them in their instincts of prowling and seizing.—MASON *Woman's Share in Primitive Culture*, ch. 2, p. 18. (A., 1894.)

3751. WOMAN IN GEOLOGY—*Original Discoveries by Lady Gordon Cumming.*—The seat of Sir William Gordon Cumming, of Altyre, is in the neighborhood of one of the Morayshire deposits discovered by Mr. Malcolmson; and for the greater part of the last two years Lady Gordon Cumming has been engaged in making a collection of its peculiar fossils, which already fills an entire apartment. The object of her ladyship was the illustration of the geology of the district, and all she sought in it on her own behalf was congenial employment for a singularly elegant and comprehensive mind. But her labors have rendered her a benefactor to science. Her collection was visited, shortly after the late meeting of the British Association in Glasgow, by Agassiz and Dr. Buckland; and great was the surprise and delight of the philosophers to find that the whole was new to geology. All the species, amounting to eleven, and at least one of the genera, that of the *Glyptolepis*, were different from any Agassiz had ever seen or described before.—MILLER *The Old Red Sandstone*, ch. 7, p. 123. (G. & L., 1851.)

3752. WOMAN, PARENTAL LOVE STRONGEST IN—*Mother's Devotion to Her Child.*—Parental love is an instinct stronger in woman than in man, at least in the early childhood of its object. I need do little more than quote Schneider's lively description of it as it exists in her:

"As soon as a wife becomes a mother her whole thought and feeling, her whole being, is altered. Until then she had only thought of her own well-being, of the satisfaction of her vanity; the whole world appeared made only for her; everything that went on about her was only noticed so far as it had personal reference to herself; she asked of every one that he should appear interested in her, pay her the requisite attention, and as far as possible fulfil her wishes. Now, however, the center of the world is no longer herself, but her child. She does not think of her own hunger, she must first be sure that the child is fed. It is nothing to her that she herself is tired and needs rest, so long as she sees that the child's sleep is disturbed; the moment it stirs she awakes, tho far stronger noises fail to arouse her now. . . . But not only the contact, the bare look of the offspring affords endless delight, not only because the mother thinks that the child will some day grow great and handsome and bring her many joys, but because she has received from Nature an instinctive love for her children. She does not herself know why she is so happy, and why the look of the child and the care of it are so agreeable, any more than the young man can give an account of why he loves a maiden, and is so happy when she is near. Few mothers, in caring for their child, think of the proper purpose of maternal love for the preservation of the species. Such a thought may arise in the father's mind; seldom in that of the mother. The latter feels only . . . that it is an everlasting delight to hold the being which she has brought forth protectingly in her arms, to dress it, to wash it, to rock it to sleep, or to still its hunger."—JAMES *Psychology*, vol. ii, ch. 24, p. 440. (H. H. & Co., 1899.)

3753. WOMAN, THE MYSTERIOUS BIFOLD LIFE OF—"The Germans believe that there is something sacred and prophetic in woman; therefore they respect the counsel of women and hearken to their judgments" (Tacitus). In fact, both of those preeminent antique nations (Greece and Rome) never regarded woman as more than a thing, always as only the servant, in no respect the partner of man, his equal in birth; while the Germans regarded woman, weak physically, as nevertheless a creature of fine intellectual development, having, therefore, a right to protection and forbearance, to reverence and sacred consideration. The emotional side of humanity was regarded her strength, that invisible, mysterious power closely related to the divine, before which one retires with a natural awe, as from something supernatural. And yet just as throughout Nature we have day and night, summer and winter, so throughout the life of the Germanic woman there runs that bipartition which on the one hand permits her to appear like unto the gods, and on the other represents her in slavish inferiority. Her legal position was entirely subordinate.—REINSCH *Stellung und Leben der deutschen Frau im Mittelalter (Virchow und Holtzendorff's Sammlung wissenschaftlicher Vorträge, 1882).* (Translated for *Scientific Side-Lights.)*

3754. WOMAN THE SUPPORT OF RELIGION — Was it accident, or a prophetic token, that Greek architecture employed superb female figures called caryatides, in the place of pillars, as supports for the halls of their temples?—HOLTZENDORFF *Frauenrechte (a Lecture).* (Translated for *Scientific Side-Lights.)*

3755. WOMAN'S CULTURE, ERRORS AFFECTING—*Highest Development of Character Required.*—Fathers and mothers are still mostly of opinion that light caliber in their daughters would find most approval from their prospective husbands. They believe that the master of the house should train his wife to suit his own taste and requirements, and think that a character of wax forms the most suitable raw material. They erroneously assume that a dependent, unenlightened creature, without any aim, is equal to the capacity for sacrifice and personal devotion. From traditions in the family, young girls acquire the notion that marriage signifies chiefly promotion in social rank,

release from parental authority doing away with manifold limitations founded on custom. All of the deeper moral relations, the most difficult duties, and the problems of self-abnegation are hidden from youth, and cannot be made comprehensible to them. But the likelihood of the fulfilment of duty does not increase with the systematic fostering of ignorance, or the fear of overculture, but with that moral effort that will not allow any year to pass without profit, with the development of ripe understanding and a firm, self-conscious will.—HOLTZENDORFF *Die Verbesserungen in der gesellschaftlichen und wirthschaftlichen Stellung der Frauen (a Lecture)*. (Translated for *Scientific Side-Lights.)*

3756. WOMAN'S MISSION—*The Struggle for the Life of Others—Motherhood—Psychical Attributes of Sex.*—That cleavage, therefore, which began in the merely physical region is now seen to extend into the psychical realm, and ends by supplying the world with two great and forever separate types. No efforts, or explanations, or expostulations can ever break down that distinction between maleness and femaleness, or make it possible to believe that they were not destined from the first of time to play a different part in human history. Male and female never have been and never will be the same. They are different in origin; they have traveled to their destinations by different routes; they have had different ends in view. The result is that they are different, and the contribution, therefore, of each to the evolution of the human race is special and unique. . . . To him [man] has been mainly assigned the fulfilment of the first great function—the struggle for life. Woman . . . is the chosen instrument for carrying on the struggle for the life of others. Man's life, on the whole, is determined chiefly by the function of nutrition; woman's by the function of reproduction. Man satisfies the one by going out into the world, and in the rivalries of war and the ardors of the chase, in conflict with Nature, and amid the stress of industrial pursuits, fulfilling the law of self-preservation; woman completes her destiny by occupying herself with the industries and sanctities of the home, and paying the debt of motherhood to her race.—DRUMMOND *Ascent of Man*, ch. 7, p. 256. (J. P., 1900.)

3757. WOMEN THE INVENTORS OF TEXTILES AND POTTERY—*Mental Power Required for Early Inventions.*—Only now and then the angry sky was lighted for the primitive man by electricity, and even then it filled him with terror. But it was he that invented the apparatus for conjuring from dried wood, by a rude sort of dynamo, the Promethean spark. It was our Aryan ancestors that paid their devotions to the rising sun by kindling fresh fire every morning as the orb of day flashed his first beam across the earth.

Who has not read with almost breaking heart the story of Palissy, the Huguenot potter? But what have our witnesses to say of that long line of humble creatures that conjured out of prophetic clay, without wheel or furnace, forms and decorations of imperishable beauty, which are now being copied in glorified material in the best factories of the world? In ceramic as well as in textile art the first inventors were women. They quarried the clay, manipulated it, constructed and decorated the ware, burned it in a rude furnace, and wore it out in a hundred uses.—MASON *The Birth of Invention (Address at Centenary of American Patent System, Washington, D. C., 1891; Proceedings of the Congress*, p. 409).

3758. WONDERS OF LIFE REVEALED BY CLOSER STUDY—*Phosphorescence of Ocean Due to Light-bearing Animals.*—The luminosity of sea-water is in part owing to living light-bearing animals, and in part to the organic fibers and membranes of the same, when in a state of decomposition. The first named of these causes of the phosphorescence of the ocean is undoubtedly the most common and the most widely diffused. The more actively and the more efficiently that travelers engaged in the study of Nature have learned to employ powerful microscopes, the more our zoological systems have been enriched by new groups of *Mollusca* and *Infusoria*, whose property of emitting light either at will or from external stimulus has been recognized. . . . The development of light [is] an organic vital process, which exhibits itself in infusorial animals as a momentary spark of light, and is repeated after short intervals of rest.—HUMBOLDT *Views of Nature*, p. 247. (Bell, 1896.)

3759. WONDERS OF NATURE—*Glacier-tables in the Alps.*—A mass of rock, having fallen on the surface of the glacier, protects the ice immediately beneath it from the action of the sun; and as the level of the glacier sinks all around it, in consequence of the unceasing waste of the surface, the rock is gradually left standing on an ice-pillar of considerable height. In proportion as the column rises, however, the rays of the sun reach its sides, striking obliquely upon them under the boulder, and wearing them away, until the column becomes at last too slight to sustain its burden, and the rock falls again upon the glacier; or, owing to the unequal action of the sun, striking, of course, with most power on the southern side, the top of the pillar becomes slanting, and the boulder slides off. These ice-pillars, crowned with masses of rock, form a very picturesque feature in the scenery of the glacier, and are represented in many of the landscapes in which Swiss artists have endeavored to reproduce the grandeur and variety of Alpine views, especially in the masterly aquarelles of Lory. The English reader will find them admirably

well described and illustrated in Dr. Tyndall's work upon the glaciers. They are known throughout the Alps as "glacier-tables."—AGASSIZ *Geological Sketches*, ser. i, ch. 8, p. 285. (H. M. & Co., 1896.)

3760. ——— ——— *Milk from Tropical Tree—The Cow-tree.*—We had already heard a good deal about this tree [the *Massaranduba*, or cow-tree], and about its producing from its bark a copious supply of milk as pleasant to drink as that of the cow. We had also eaten its fruit in Para, where it is sold in the streets by negro market-women, and had heard a good deal of the durableness in water of its timber. We were glad, therefore, to see this wonderful tree growing in its native wilds. It is one of the largest of the forest monarchs, and is peculiar in appearance on account of its deeply scored, reddish, and ragged bark. A decoction of the bark, I was told, is used as a red dye for cloth. A few days afterward we tasted its milk, which was drawn from dry logs that had been standing many days in the hot sun at the sawmills. It was pleasant with coffee, but had a slight rankness when drank pure; it soon thickens to a glue, which is excessively tenacious, and is often used to cement broken crockery. I was told that it was not safe to drink much of it, for a slave had recently nearly lost his life through taking it too freely.—BATES *Naturalist on the River Amazon*, ch. 2, p. 635. (Hum., 1880.)

3761. WONDERS OF SUPERSTITION SURPASSED BY THE WONDERS OF SCIENCE—*Distances from which Comets Come—Millions of Years on Their Way—Witnesses of Vanished Eras—Ancient Testimony of the Existence of Matter.*—Do we ever think what an immense voyage they [comets] must have made to come from there to here? Do we imagine for how many years they must have flown through the dark immensity to plunge themselves into the fires of our sun? If we take into account the directions from which certain comets come to us, and if we assign to the stars situated in that region the least distances consistent with known facts, we find that these comets certainly left their last star more than 20,000,000 years ago.

In thus putting to us from the height of their celestial apparitions so many notes of interrogation on the grandest problems of creation, comets assume to our eyes an interest incomparably greater than that with which superstition blindly surrounded them in past ages. When we reflect for a moment that a certain comet which shines before us in the sky came originally from the depths of the heavens, that it has traveled during millions of years to arrive here, and that, consequently, it is by millions of years that we must reckon its age if we wish to form any idea of it, we cannot refrain from respecting this strange visitor as a witness of vanished eras, as an echo of the past, as the most ancient testimony which we have of the existence of matter. But what do we say? These bodies are neither old nor young; there is nothing old, nothing new; all is present: the ages of the past contemplate the ages of the future, which all work, all gravitate, all circulate in the eternal plan. Musing, you look at the river which flows so gently at your feet, and you believe you see again the river of your childhood; but the water of to-day is not that of yesterday; it is not the same substance which you have before your eyes, and never, never shall this union of molecules, which you behold at this moment, come back there, never till the consummation of the ages!—FLAMMARION *Popular Astronomy*, bk. v, ch. 3, p. 528. (A.)

3762. WONDERS, SCIENCE DOES NOT MAKE LESS—*An Explanation Is a Statement of a Grander Fact—Gravitation a Marvelous Truth.*—People are apt to think that when the scientific explanation of a fact is given, the fact in question ceases to be wonderful. But if we would but reflect, we should see that this explanation is only another fact of a more general kind, and one which ought, therefore, to be regarded as more striking, one which ought to incite us to more curious inquiry. That a stone, dropped in the air, falls to the ground, is so familiar an experience that it could excite wonder only in the most reflective minds. But when it did excite wonder and curiosity, the fact was made not less, but much more wonderful when its scientific explanation was furnished in Newton's law of gravitation—a law according to which we find that a stone is, as it were, drawn to the earth by a force which can be measured, and by which the earth acts on the moon precisely in the same way as it does upon a stone dropped in the air. That explanation is a very wonderful fact, one that leads men of science to inquire why this should be so, tho it requires a scientific training to appreciate that kind of curiosity. —CHISHOLM *Nature-Studies*, p. 26. (Hum., 1888.)

3763. WORD ASSOCIATED WITH ITS MEANING—*Empty Repetition Gives Feeling of Unnaturalness.*—This [difference between perception of particulars and of a whole which includes them] is probably the reason why, if we look at an isolated printed word and repeat it long enough, it ends by assuming an entirely unnatural aspect. Let the reader try this with any word on this page. He will soon begin to wonder if it can possibly be the word he has been using all his life with that meaning. It stares at him from the paper like a glass eye, with no speculation in it. Its body is indeed there, but its soul is fled. It is reduced, by this new way of attending to it, to its sensational nudity. We never before attended to it in this way, but habitually got it clad with its meaning the moment

we caught sight of it, and rapidly passed from it to the other words of the phrase. We apprehended it, in short, with a cloud of associates, and, thus perceiving it, we felt it quite otherwise than as we feel it now divested and alone.—JAMES *Psychology*, vol. ii, ch. 19, p. 80. (H. H. & Co., 1899.)

3764. WORDS, THEIR UNDYING POWER—In all . . . later studies, verbal material is the vehicle by which the mind thinks. The abstract conceptions of physics and sociology may, it is true, be embodied in visual or other images of phenomena, but they need not be so; and the truth remains that, after adolescence has begun, "words, words, words" must constitute a large part, and an always larger part as life advances, of what the human being has to learn. This is so even in the natural sciences, so far as these are causal and rational, and not merely confined to description.—JAMES *Talks to Teachers*, ch. 12, p. 149. (H. H. & Co., 1900.)

3765. WORK, ANCIENT AND MODERN, COMPARED—*How Machinery Would Rebuild the Great Pyramid.*—I know we are frequently referred to the immense masses of stone transported and wrought by ancient art, which are found among the ruins of Baalbec and Thebes, and are frequently told that the management of these would far transcend the skill and power of modern engineers. Such assertions are, however, rather intended to convey an idea of the impression produced upon the beholder of these venerable ruins than a declaration of absolute truth. As a sufficient illustration of this we may mention the fact that in New York large buildings of brick and stone are moved from place to place while the inhabitants remain undisturbed within; or we may point to the Menai Strait tubular bridge, a structure of cast-iron several hundred tons in weight, suspended in mid air over a chasm more than a hundred feet deep.

The pyramid of Cheops is said to have employed the power of 100,000 men for twenty years in its erection; but, vast as is this pile, were the steam-engines employed in one of our large cities directed to the task of rearing one of equal magnitude the whole would be accomplished in a few weeks.—HENRY *Improvement of the Mechanical Arts (Scientific Writings*, vol. i, p. 321). (Sm. Inst., 1886.)

3766. WORK A SPECIFIC—*Rest Joyful Because of Previous Toil.*—Sooner or later every intellectual canker disappears before earnest work, the influence of which, moreover, fills a wide margin beyond the time of its actual performance. Thus, to-day, I sang as I rolled along—not with boisterous glee, but with serene and deep-lying gladness of heart. This happiness, however, had its roots in the past, and, had I not been a worker previous to my release from London, I could not now have been so glad an idler. In any other country than Switzerland the valley through which we sped would have called forth admiration and delight. Noble fells, proudly grouped, flanked us right and left. Cloudlike woods of pines overspread them in broad patches, with between them spaces of the tenderest green, while among the meadows at their feet gleamed the rushing Rhine.—TYNDALL *Hours of Exercise in the Alps*, ch. 5, p. 62. (A., 1898.)

3767. WORK, INCESSANT, OF INSECTS—*Industry of Ants—Long Days of Labor—Persevering Toil.*—In industry ants are not surpassed even by bees and wasps. They work all day, and in warm weather, if need be, even at night, too. I once watched an ant from six in the morning, and she worked without intermission till a quarter to ten at night. I had put her to a saucer containing larvæ, and in this time she carried off no less than a hundred and eighty-seven to the nest. I had another ant, which I employed in my experiments, under continuous observation several days. When I started for London in the morning, and again when I went to bed at night, I used to put her in a small bottle, but the moment she was let out she began to work again. On one occasion I was away from home for a week. On my return I took her out of the bottle, placing her on a little heap of larvæ about three feet from the nest. Under these circumstances I certainly did not expect her to return. However, tho she had thus been six days in confinement, the brave little creature immediately picked up a larva, carried it off to the nest, and after half an hour's rest returned for another.—AVEBURY *Ants, Bees, and Wasps*, ch. 1, p. 27. (A., 1900.)

3768. WORK INVOLVES THE UNDOING OF SOME PREVIOUS WORK—*Clock—Mill-wheel—Rifle.*—Whenever work is done, it is by the undoing of some previous work. When a clock moves, it is the unwinding of a spring or the falling of a weight which keeps it going, and some one must have wound it up to begin with. If the water of a river falls year after year over a cataract, and is intercepted to drive our mill-wheels, the river continues to run because some power [that of the sun] is continually raising and returning to the hilltops the water which has flowed into the sea—a process precisely equivalent to the daily rewinding of the clock. If the powder in a rifle explodes and drives out the bullet, its explosive energy depends upon the fact that some power has placed the component molecules in such relations that, when the trigger is pulled, and the exciting spark has, so to speak, cut the bonds which hold them apart, they rush together just as suspended weights would fall if freed. Before the same substance, which once was a charge of gunpowder, but now is dust and gas, can again do the same work, the prod-

ucts of the explosion must by some power be decomposed, and the atoms replaced in the same relations as before the firing of the gun; and this process is mechanically analogous to the lifting of fallen weights and placing them upon elevated shelves, or hanging them from hooks, ready to drop again when the occasion may require.—YOUNG *The Sun*, int., p. 3. (A., 1898.)

3769. WORK OF MAN AND WOMAN AMONG ABORIGINES—*Carving for Man—Basketry and Pottery for Woman—White Man's Tools Not an Improvement.*—There ought to be no doubt that in every case where the savage was fortunate enough to obtain the knife his carving and whittling were better done. There is a marvelous difference between carving, on the one hand, man's work chiefly, and basketry or pottery, on the other, conservative woman's work. In no tribes were the two last-named arts bettered by contact with the higher race. The work was done with the hands almost wholly. The tools were of the simplest character. The harsh iron awl was not so good as the smooth-pointed bone awl, of which hundreds have been found, and the pride in personal endeavor departed with the quenching of the tribal spirit. The potter's wheel, such as it was three centuries ago, was only a barrier to the unmechanical sex. Therefore those who constantly assert that prejudice made it impossible for the savage to better himself in the adoption of the white man's devices catch only half a truth. —MASON *The Man's Knife among the North American Indians (Report of U. S. National Museum for 1897*, p. 727).

3770. WORK OF WOMAN THE CALENDAR OF PRIMITIVE MAN—The work of the men among the Omahas, according to Dorsey, was regulated essentially by that of the women, who were to them a sort of calendar. The summer hunt was undertaken after the women had planted the corn and the pumpkins, and the beans had been gathered. They returned on the ripening of the sunflower. They went on the fall hunt when the hair on the game was thick and warm, out of which the women made the clothing. The women buried in caches whatever they wished to leave. Food, etc., was placed in a blanket, which was gathered at the corners and tied with a thong; then the bundle was allowed to fall at the bottom of the cache. Then the women went over the corn fields to see that all the work had been finished. They prepared pack-saddles and litters and mended moccasins and other clothing. The day for the departure having arrived, the women loaded their horses and dogs and took as great weights on their own backs as they could conveniently transport. —MASON *Woman's Share in Primitive Culture*, int., p. 9. (A., 1894.)

3771. WORK UNFINISHED—*Tools of Ancient Miners Found as Left in Distant Age.*—In one case the roof of a passage had given way. On removing the chalk which had fallen in, the end of the gallery came in view. The flint had been hollowed out in three places, and in front of two of these recesses, pointing towards the half-excavated stone, were two deer-horn picks, lying just as they had been left, still coated with chalk dust, on which was in one place plainly visible the print of the workman's hand. The tools had evidently been left at the close of a day's work; during the night the gallery had fallen in, and they had never been recovered.

"It was a most impressive sight," says Mr. Greenwell, "and one never to be forgotten, to look, after a lapse, it may be, of 3,000 years, upon a piece of work unfinished, with the tools of the workmen still lying where they had been placed so many centuries ago."—AVEBURY *Prehistoric Times*, ch. 4, p. 79. (A., 1900.)

3772. WORK WROUGHT BY THE SUN ON EARTH—*Calculation in Horse-power.*—The sun is the mighty source from which proceed all the forces which set in motion the earth and its life. It is its heat which causes the wind to blow, the clouds to ascend, the river to flow, the forest to grow, the fruit to ripen, and man himself to live. The force constantly and silently expended in raising the reservoirs of rain to their mean atmospheric height, in fixing the carbon in the plants, in giving to terrestrial Nature its vigor and its beauty, has been calculated from a mechanical point of view; it is equal to the work of 217,316,000,000,000 horse-power; 543 milliards (543,000,000,000) of steam-engines, each with an effective power of 400 horses, would have to work day and night without intermission: such is the permanent work of the sun upon the earth.—FLAMMARION *Popular Astronomy*, bk. iii, ch. 3, p. 245. (A.)

3773. WORKER, INSIGNIFICANT, ACHIEVES VAST RESULTS—*Progress against Resistance—Coral Islands.*—Every one must be struck with astonishment when he first beholds one of these vast rings of coral rock [the atolls], often many leagues in diameter, here and there surmounted by a low, verdant island, with dazzling white shores, bathed on the outside by the foaming breakers of the ocean, and on the inside surrounding a calm expanse of water, which, from reflection, is generally of a bright but pale green color. The naturalist will feel this astonishment more deeply after having examined the soft and almost gelatinous bodies of these apparently insignificant coral polypifers, and when he knows that the solid reef increases only on the outer edge, which day and night is lashed by the breakers of an ocean never at rest.—DARWIN *Coral Reefs*, int., p. 1. (A., 1898.)

3774. WORLD, A DIVIDED—*Barrier which the Inorganic Cannot Cross—Biogenesis.*—What essentially is involved in saying

that there is no spontaneous generation of life? It is meant that the passage from the mineral world to the plant or animal world is hermetically sealed on the mineral side. This inorganic world is staked off from the living world by barriers which have never yet been crossed from within. . . . Only by the bending down into this dead world of some living form can these dead atoms be gifted with the properties of vitality; without this preliminary contact with life they remain fixed in the inorganic sphere forever. It is a very mysterious law which guards in this way the portals of the living world. And if there is one thing in Nature more worth pondering for its strangeness it is the spectacle of this vast, helpless world of the dead cut off from the living by the law of biogenesis and denied forever the possibility of resurrection within itself. So very strange a thing, indeed, is this broad line in Nature that science has long and urgently sought to obliterate it. Biogenesis stands in the way of some forms of evolution with such stern persistency that the assaults upon this law for number and thoroughness have been unparalleled. But, as we have seen, it has stood the test. Nature, to the modern eye, stands broken in two. "The present state of knowledge furnishes us with no link between the living and the not-living." (Huxley, "Encyclopædia Britannica," new ed., art. "Biology.")—DRUMMOND *Natural Law in the Spiritual World*, essay 1, p. 61. (H. Al.)

3775. WORLD LIGHTED BY A BLUE AND AN ORANGE SUN—*Its Strange Varieties of Day and Night.*—In the first place, let us take the case where the world is between the orange sun and the blue one, and let us suppose that the season corresponds to our spring. Then it is manifest that since one sun illumines one side of the globe, and the other illumines the other, there can be no night; it is orange day to one half of the world, and blue day to the other. Moreover, since the season corresponds to our springtime, it follows that orange day lasts exactly as long as blue day, and using for convenience the division of the day into twenty-four hours (which may or may not be nearly the same as our terrestrial hours), there are, all over the world, twelve hours of orange day and twelve hours of blue day. This, however, would not last very long, any more than on our own earth we have Jupiter visible all night for any length of time. The blue sun would gradually take up the position which Jupiter has when he is an evening star. . . . The blue sun would, in fact, rise before the orange sun had set. Thus there would be orange day as before, but towards orange sunset there would be two suns, the orange sun nearing the west, the blue sun passing over the eastern horizon. Then would come orange sunset and blue day; but the blue sun would set before the orange sun rose, and there would be, therefore, a short night, tho, no doubt, not a dark night, since there would be blue twilight in the west and orange twilight in the east. Gradually the length of this night would increase, the length of the double day also increasing, but the orange and blue hours gradually shortening. At length the blue sun would have drawn quite near to the place of the orange sun in the heavens, and there would be double day and night, but neither orange day nor blue day alone. The double day would probably be white, since the colors of the two suns are supposed to be complementary. After this the blue sun would pass to the other side (the west) of the orange sun, and would be placed like Jupiter when he is a morning sun. There would then be blue morning, white day, orange evening, and night, the night gradually growing shorter and shorter, until at length the blue sun would be opposite the orange sun, and there would be no night, but simple alternation of blue day and orange day, as at first.—PROCTOR *Expanse of Heaven*, p. 229. (L. G. & Co., 1897.)

3776. WORLD THE PRODUCT OF WARRING SYSTEMS—*Doctrines of Gnostics and Manichæans.*—Some Gnostics went so far as to hold that the world was originally created by the devil, and is to be gradually purified and redeemed by the beneficent power of God as manifested through Jesus Christ. This notion is just the opposite to that of the Vendidad, which represents the world as coming into existence pure and perfect, only to be forthwith defiled by the trail of the serpent Ahriman. In both these opposing theories the divine power is distinctly and avowedly curtailed by the introduction of a rival power that is diabolical; upon this point Parsee and Gnostic are agreed. Distinct sources are postulated for the evil and the good. The one may be regarded as infinite in goodness, the other as infinite in badness, and the world in which we live is [held to be] a product of the everlasting conflict between the two.—FISKE *Through Nature to God*, pt. i, ch. 3, p. 14. (H. M. & Co., 1900.)

3777. WORLD, UNSEEN, OF FUNDAMENTAL IMPORTANCE—*The Consummation of Evolution There.*—So far as our knowledge of Nature goes, the whole momentum of it carries us onward to the conclusion that the unseen world, as the objective term in a relation of fundamental importance that has coexisted with the whole career of mankind, has a real existence; and it is but following out the analogy to regard that unseen world as the theater where the ethical process is destined to reach its full consummation.—FISKE *Through Nature to God*, pt. iii, ch. 10, p. 190. (H. M. & Co., 1900.)

3778. WORLD WITHOUT AN ATMOSPHERE—*Effects of Rarefied Air—Opposites Unite—The Sun's Rays Burn amid Wintry Cold.*—[The investigator cannot go to the moon]; but he may go if he pleases, as I have done, to the waterless, shadeless waste which stretches at the eastern slope of the Sierra Nevadas. . . . The sky is cloudless, and the air so clear that all idea of the real distance and size of things is lost. The mountains, which rise in tremendous precipices above him, seem like moss-covered rocks close at hand, on the tops of which, here and there, a white cloth has been dropped; but the "moss" is great, primeval forests, and the white cloths large isolated snow-fields, tantalizing the dweller in the burning desert with their delusive nearness. When I climbed the mountains, at an altitude of ten thousand feet I already found the coolness delicious, but at the same time (by the strange effect I have been speaking of) the skin began to burn, as tho the seasoning in the desert counted for nothing at all; and as the air grew thinner and thinner while I mounted still higher and higher, tho the thermometer fell, every part of the person exposed to the solar rays presented the appearance of a recent severe burn from an actual fire—and a really severe burn it was, as I can testify—and yet all the while around us, under this burning sun and cloudless sky, reigned a perpetual winter which made it hard to believe that torrid summer still lay below. The thinner the air, then, the colder it grows, even where we are exposed to the sun, and the lower becomes the reading of the thermometer. Now, by means of suitable apparatus, it was sought by the writer to determine, while at this elevation of fifteen thousand feet, how great the fall of temperature would be if the thin air there could be removed altogether; and the result was that the thermometer would under such circumstances fall, at any rate, below zero in the full sunshine.—LANGLEY *New Astronomy*, ch. 5, p. 160. (H. M. & Co., 1896.)

3779. WORLDS ALWAYS IN THE LIGHT—*Every Star a Sun—"There Shall Be No Night There" (Rev. xxi, 25; xxii, 5).*—We can . . . form some idea of the wonderful scene presented to the inhabitants of such a world [circling round one sun of a star-cluster], because in reality it is no other than that, which would be presented to ourselves if all the stars seen on the darkest and clearest night were to grow suddenly in luster until the faintest shone with light enough alone to banish night. The wonderful scene thus presented must be carried round by a stately motion of rotation precisely as happens with our own star sphere. Suns must be always rising and always setting, only the magnificent colors which adorn our skies at sunrise and sunset must be wanting there, banished by the excess of splendor. It is manifest that, at least when the sky is clear, there can be no shadows in the landscapes on those distant worlds, since every quarter of the sky must have its suns. When the sky is partially clouded there will be shadows, tho not well-defined shadows such as we recognize, but rather the lightest possible shade on those sides of objects which lie towards the clouded portion of the sky. —PROCTOR *Expanse of Heaven*, p. 217. (L. G. & Co., 1897.)

3780. ——— ——— *Night Unknown to Dwellers amid Star-clusters.*—I have spoken thus far of but two stars out of the thousands on thousands composing the star-cluster. All these thousands would shine with a brightness enormously exceeding that of any of the stars we see, and many hundreds among them would appear as suns, smaller than the two nearest suns before considered, but bright enough with their sole luster to banish night.

It follows, then, that to a globe placed as we have supposed, and traveling around one or other of the suns composing the cluster, night would be absolutely unknown. There would be different degrees of daylight, from the broadest day on the part of the globe turned fully towards the nearest sun, to a less brilliant day on the opposite part turned to other suns, but always day, often very much brighter than our summer noon, and seldom fainter, since the number of suns would make up for the comparative smallness of each.—PROCTOR *Expanse of Heaven*, p. 209. (L. G. & Co., 1897.)

3781. WORLDS, OTHER, MAY BE INHABITED—*Conditions of Life on Mars—Supposed Inhabitants.*—Such is the general physiology of this neighboring planet [Mars]. The atmosphere which surrounds it, the waters which irrigate and fertilize it, the rays of the sun which warm and illuminate it, the winds which pass over it from one pole to the other, the seasons which transform it, are so many elements from which to construct for it an order of life analogous to that which has been conferred on our planet. The weakness of gravity at its surface must materially modify this order of life in adapting it to its special condition. Henceforth the globe of Mars should no longer be presented to us as a block of stone revolving in the midst of the void, in the sling of the solar attraction, like an inert, sterile, and inanimate mass; but we should see in it a living world, adorned with landscapes similar to those which charm us in terrestrial Nature; a new world which no Columbus will ever reach, but on which, doubtless, a human race now resides, works, thinks, and meditates as we do on the great and mysterious problems of Nature. These unknown brothers are not spirits without bodies, or bodies without spirits, beings supernatural or extranatural, but active beings, thinking, reasoning as we do here.

They live in society, are grouped in families, associated in nations, have raised cities, and conquered the arts. Doubtless, their senses of sight and hearing do not differ essentially from ours, and if we happened to pass a day not far from their abodes, we should perhaps be surprised with their architecture, or charmed by the echo of melodious harmony, reminding us of the musical inspirations of our great masters. In the midst of varieties inherent to planetary diversities and the secular metamorphoses of worlds, we should find the same vital torch kindled on all the spheres.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 4, p. 397. (A.)

3782. ——— ——— *Experience Not the Measure of Possibility—Increase of Knowledge Leads to Modesty of Judgment—Life in Ocean Depths.*—We are apt to forget that the forms of life we are accustomed to are not necessarily the only possible forms of life. It is almost impossible to say under what conditions life is possible or impossible. Men of science have lately been taught this in a very striking manner. For, judging by what they know of the state of things at the bottom of the deep sea, they concluded that there could be no living creatures there. They reasoned that the pressure exerted by the water would crush the life out of any known creature, which was unquestionably true. . . . The tremendous mail of the crocodile or the thick skin of the rhinoceros would be unable to resist a tithe of the enormous pressure exerted by the water at the bottom of deep seas. Yet it is now known that creatures not only exist down there, but that, notwithstanding the great darkness which must prevail there, these creatures are provided with the means of seeing. So unlike are they to all other creatures, however, that they are unable to live out of their native depths, and when dragged up by the dredges they burst asunder and are killed long before reaching the surface. This should teach us that altho it may be proved that in some inaccessible world, like Venus or any of her fellow planets, the conditions which prevail are not such as would be convenient to terrestrial creatures, or are even such that no creatures known to us could endure them even for a few minutes, life may nevertheless exist.—PROCTOR *Expanse of Heaven*, p. 49. (L. G. & Co., 1897.)

3783. ——— ——— *Neptune—Life in Ocean Depths—Supposed Impossibility Overcome.*—Is this equivalent to saying that this world [Neptune] is condemned to remain eternally in the state of a sterile and uninhabited desert? Nature herself replies that such a supposition would be entirely contrary to her acts and her views. Short-sighted naturalists, who think they know everything, would teach dogmatically that a pressure of so many atmospheres prevents life from being produced; that a certain amount of light is indispensable to life, and that the ocean depths are absolutely destitute of all vital manifestation. A ship starts on an immense liquid plain to visit the equatorial and polar zones, casts the sounding-line at 2,000 fathoms, at 10,000 feet in depth, in eternal night—a black darkness, where the pressure is such that could a man descend there he would have to support a weight equal to that of twenty locomotives, each accompanied by a train of wagons loaded with bars of iron. Evidently there is nothing there! The sounding-line is drawn in, however, and brings up charming, delicate beings which the lightest touch of the finger of Psyche would kill: they live there tranquil, happy, "like the fish in water," and, since there is no light there, they make it! If they could understand you, you should not speak to them of your castles, your parks and venerable trees, nor of the Paris worldling and the boulevards which you love so much; they prefer their abode, their dark abode in the depths of the sea, scarcely illuminated with the light of their own phosphorescence, and to them there is the true medium, there is real happiness. And when you cast these living débris on the deck of the ship, and when these marvelous beings with variegated embroideries die before your eyes, overwhelmed by the light of the sky, suffocated by the rarefaction of the air which nourishes your lungs, do you not think of Neptune? Do you not see that the god of the ocean has down there an empire as vast as the one we see? And as they have there 900 times less light and heat than on the deck of your ship, you imagine that Nature has been unable to produce anything there! Error, foolish, insane error, excusable, perhaps, in the time of Aristotle, but absolutely unpardonable now.—FLAMMARION *Popular Astronomy*, bk. iv, ch. 9, p. 469. (A.)

3784. WORMS AS BUILDERS—*Intelligent Skill Shown in the Lining of Their Burrows.*—Many leaves of the Scotch fir or pine *(Pinus sylvestris)* were given to worms kept in confinement in two pots; and when after several weeks the earth was carefully broken up, the upper parts of three oblique burrows were found surrounded for lengths of 7, 4, and 3½ inches with pine leaves, together with fragments of other leaves which had been given the worms as food. Glass beads and bits of tile, which had been strewed on the surface of the soil, were stuck into the interstices between the pine leaves; and these interstices were likewise plastered with the viscid castings voided by the worms. The structures thus formed cohered so well that I succeeded in removing one with only a little earth adhering to it. It consisted of a slightly curved cylindrical case, the interior of which could be seen through holes in the sides and at either end. The pine leaves had all been drawn in by their bases, and the sharp points of the needles had been pressed into the lining

of voided earth. Had this not been effectually done, the sharp points would have prevented the retreat of the worms into their burrows; and these structures would have resembled traps armed with converging points of wire, rendering the ingress of an animal easy and its egress difficult or impossible. The skill shown by these worms is noteworthy, and is the more remarkable, as the Scotch pine is not a native of this district.—DARWIN *Formation of Vegetable Mould*, ch. 2, p. 113. (A., 1882.)

3785. WORMS PREPARE GROUND FOR SEED—*Trituration, Aeration, and Mixing of Soil.*—Worms prepare the ground in an excellent manner for the growth of fibrous-rooted plants and for seedlings of all kinds. They periodically expose the mold to the air, and sift it so that no stones larger than the particles which they can swallow are left in it. They mingle the whole intimately together, like a gardener who prepares fine soil for his choicest plants. In this state it is well fitted to retain moisture and to absorb all soluble substances, as well as for the process of nitrification. The bones of dead animals, the harder parts of insects, the shells of land mollusks, leaves, twigs, etc., are before long all buried beneath the accumulated castings of worms, and are thus brought in a more or less decayed state within reach of the roots of plants. Worms likewise drag an infinite number of dead leaves and other parts of plants into their burrows, partly for the sake of plugging them up and partly as food.

The leaves which are dragged into the burrows as food, after being torn into the finest shreds, partially digested, . . . are commingled with much earth. This earth forms the dark-colored, rich humus which almost everywhere covers the surface of the land with a fairly well-defined layer or mantle.—DARWIN *Formation of Vegetable Mould*, ch. 7, p. 310. (A., 1882.)

3786. WORSHIP OF MAGNETIC NEEDLE IN CHINA—To the magnet the Chinese have always paid divine honors. "An astonishing number of offerings," says the missionary Gutzlaff, "are brought to the magnet; a piece of red cloth is thrown over it, incense is kindled before it, and gold paper, in the form of a Chinese ship, is burned." Barrow also notes that a Chinese navigator not only considers the magnet needle as a guide to direct his track through the ocean, but is persuaded that the spirit by which its motions are influenced is the guardian deity of his vessel.—PARK BENJAMIN *Intellectual Rise in Electricity*, ch. 3, p. 80. (J. W., 1898.)

3787. WORTH OF CULTURE SHOWN BY ITS LACK—*Plants Unimproved among Savages.*—If it has taken centuries or thousands of years to improve or modify most of our plants up to their present standard of usefulness to man, we can understand how it is that neither Australia, the Cape of Good Hope, nor any other region inhabited by quite uncivilized man, has afforded us a single plant worth culture. It is not that these countries, so rich in species, do not by a strange chance possess the aboriginal stocks of any useful plants, but that the native plants have not been improved by continued selection up to a standard of perfection comparable with that acquired by the plants in countries anciently civilized.—DARWIN *Origin of Species*, ch. 1, p. 32. (Burt.)

3788. WRETCHEDNESS OF SAVAGERY—*The Fuegians.*—While going one day [in 1832] on shore near Wollaston Island, we pulled alongside a canoe with six Fuegians. These were the most abject and miserable creatures I anywhere beheld. . . . These poor wretches were stunted in their growth, their hideous faces bedaubed with white paint, their skins filthy and greasy, their hair entangled, their voices discordant, and their gestures violent. Viewing such men, one can hardly make oneself believe that they are fellow creatures, and inhabitants of the same world. It is a common subject of conjecture what pleasure in life some of the lower animals can enjoy: how much more reasonably the same question may be asked with respect to these barbarians! At night five or six human beings, naked and scarcely protected from the wind and rain of this tempestuous climate, sleep on the wet ground coiled up like animals. Whenever it is low water, winter or summer, night or day, they must rise to pick shellfish from the rocks; and the women either dive to collect sea-eggs, or sit patiently in their canoes, and with a baited hair-line without any hook jerk out little fish. If a seal is killed, or the floating carcass of a putrid whale discovered, it is a feast; and such miserable food is assisted by a few tasteless berries and fungi.—DARWIN *Naturalist's Voyage around the World*, ch. 10, p. 212. (A., 1898.)

3789. WRITING ACROSS SPACE—*The Telautograph—Celerity, Accuracy, and Identification.*—In 1893 there was exhibited in the electrical building at the World's Fair an instrument invented by the writer called the telautograph. As the word implies, it is a system by which a man's own handwriting may be transmitted to a distance through a wire and reproduced in facsimile at the receiving end. . . . As one writes his message in one city another pen in another city follows the transmitting-pen with perfect synchronism; it is as tho a man were writing with a pen with two points widely separated, both moving at the same time and both making exactly the same motions. By this system a man may transact business with the same accuracy as by the United States mail, and with the same celerity as by the electric telegraph.

A broker may buy or sell with his own signature attached to the order, and do it

as quickly as he could by any other method of telegraphing, and with absolute accuracy, secrecy, and perfect identification. . . . Companies have been organized both in Europe and America for the purpose of putting the telautograph into commercial use.—ELISHA GRAY *Nature's Miracles*, vol. iii, ch. 19, p. 165. (F. H. & H., 1900.)

3790. WRITING DIVIDES CIVILIZED MAN FROM BARBARIAN—*Makes Accumulation of Knowledge Possible.*—The invention of writing was the great movement by which mankind rose from barbarism to civilization. How vast its effect was may be best measured by looking at the low condition of tribes still living without it, dependent on memory for their traditions and rules of life, and unable to amass knowledge as we do by keeping records of events, and storing up new observations for the use of future generations. Thus it is no doubt right to draw the line between barbarian and civilized where the art of writing comes in, for this gives permanence to history, law, and science.—TYLOR *Anthropology*, ch. 7, p. 179. (A., 1899.)

3791. WRITING, EVOLUTION OF—*At First Imitative—The Hieroglyph—Chinese Picture-writing—Its Shorthand Modern Form.*—From being able to say what he knew, man went on to write what he knew. The evolution of writing went through the same general stages as the evolution of speech. First there was the onomatopœic writing—as it were, the growl-writing—the ideograph, the imitation of an actual object. This is the form we find fossil in the Egyptian hieroglyphic. For a man a man was drawn, for a camel a camel, for a hut a hut. Then intonation was added—accents, that is, for extra meaning or extra emphasis. Then to save time the objects were drawn in shorthand—a couple of dashes for the limbs and one across, as in the Chinese for man: a square in the same language for a field; two strokes at an obtuse angle, suggesting the roof for a house. To express further qualities, these abbreviated pictures were next compounded in ingenious ways. A man and a field together conveyed the idea of wealth, and because a man with a field was rich, he was supposed to be happy, and the same combination stood, and stands to this day, for contentment. When a roof is drawn and a woman beneath it—or the strokes which represent a roof and a woman—we have the idea of a woman at home, a woman at peace, and hence the symbol comes to stand for quietness and rest. Chinese writing is picture-writing, with the pictures degenerated into dashes—a lingual form of the modern impressionism.—DRUMMOND *Ascent of Man*, ch. 5, p. 182. (J. P., 1900.)

3792. WRITING EXTENDS MAN'S HORIZON IN SPACE AND TIME—*Eye-mindedness vs. Ear-mindedness—Accurate Thinking Promoted by Permanence of Visible Symbols.*—Man is an animal who as individual can become a species by acquiring the knowledge and power, the experience and wisdom, of his race. But how limited is this power with the illiterate person! By means of letters one comes to be able to put down his life-experience in written and printed words, and all persons who can read get the power of living over his experience, interpreting the signs which are addressed to the eye and not to the ear. Through letters the person becomes eye-minded, and when a person can read without effort he finds himself in possession of a much more accurate mind than is possible in the case of the illiterate. Ear-mindedness, having to keep up as it does with the spoken word, and having to depend on the memory of what is spoken, cannot critically examine the statements and descriptions, the definitions and deductions, as it can do when it has before it the printed page. In fact, accurate thinking for the most part becomes possible through eye-mindedness and not through ear-mindedness. Then just think of the scope which eye-mindedness attains! It does not depend at all upon the living voice, but it can become participant in the experience of persons at a distance, of all nationalities dwelling in all parts of the world. It is not limited by time. It can make available for its use the writings of all peoples that belong to the historical era, and, in fact, it can use the experience even of the peoples whose only records are monuments and written tablets of the prehistoric era.

Think of the meaning of this for the development of individuality . . . the peculiar index-mark of the nineteenth century! For individuality grows through the appropriation or assimilation of other individuality, and while the ear-minded person can command by means of wealth the services of oral teachers, and gains his instruction through absorbing the lives of his oral teachers, the eye-minded, on the other hand, can command the services of the book, and the book awaits his leisure. All parts of the earth become to him substantially present like his own village. Not merely ordinary teachers come to his service, but the wise men of his race await his leisure in the books which he possesses. These facts about ear-mindedness and eye-mindedness seem trite like a twice-told tale, but few persons are in the habit of thinking what a difference it makes with an entire people to pass from ear-mindedness to eye-mindedness through the beneficent influences of the common schools. . . . As an eye-minded people, with us world gossip has taken the place of village gossip in its hold on our lives.—HARRIS *The Movement from Individualism to Cosmopolitanism (an Address at the National Educational Association, Chicago, Ill., 1900; Proceedings of the Association*, p. 14).

3793. YEARS SHORTEN WITH ADVANCING AGE—*The Novelty of Youth Has Become Routine.*—The same space of time

seems shorter as we grow older—that is, the days, the months, and the years do so; whether the hours do so is doubtful, and the minutes and seconds to all appearance remain about the same. . . . In youth we may have an absolutely new experience, subjective or objective, every hour of the day. Apprehension is vivid, retentiveness strong, and our recollections of that time, like those of a time spent in rapid and interesting travel, are of something intricate, multitudinous, and long drawn out. But as each passing year converts some of this experience into automatic routine which we hardly note at all, the days and the weeks smooth themselves out in recollection to contentless units, and the years grow hollow and collapse.—JAMES *Psychology*, vol. i, ch. 15, p. 625. (H. H. & Co., 1899.)

3794. YIELDING A BETTER PROTECTION THAN HARDNESS—*Flexible Buildings Best Withstand Earthquakes.*—From [an examination of] the different buildings found in earthquake countries, it will be seen that if we wish to put up a building able to withstand a severe shaking we have before us structures of two types. One of these types may be compared with a steel box, which, even were it rolled down a high mountain, would suffer but little damage; and the other, with a wicker basket, which would equally withstand so severe a test. Both of these types may be, to some extent, protected by placing them upon a loose foundation, so that but little momentum enters them at their base.

One suggestion is to place a building upon iron balls. The author found that the most practical form of free foundation was to rest the building upon layers of cast-iron shot, each shot being about one-quarter inch in diameter. Another method would be to place them upon two sets of rollers, one set resting upon the other set at right angles. The sole-plates of a Japanese house rest freely on more or less rounded stones. The solid type of building is expensive, and can only be approached partially, whilst the latter is cheap, and can be approached closely. In the case of a solid building it would be a more difficult matter to support it upon a movable foundation than in the case of a light framework. Such a [solid] building is usually firmly fixed on the ground, and consequently at the time of an earthquake, as has already been shown by experiment, must be subjected to stresses which are very great. In consequence also of the greater weight of the solid structure, the effects due to its own inertia will be augmented. Also, we must remember that the rigidity favors the transmission of momentum, and with rigid walls we are likely to have ornaments, coping-stones, and the comparatively freer portions forming the upper part of a building displaced; whilst, with flexible walls, absorbing momentum in the friction of their various parts, such disturbances would not be so likely.—MILNE *Earthquakes*, ch. 7, p. 127. (A., 1899.)

3795. ——— ——— *Tracery of Fine Fabrics on Glass.*—By protecting certain portions of the surface [of glass, from the sand-blast], and exposing others, figures and tracery of any required form could be etched upon the glass. The figures of open iron-work could be thus copied; while wire-gauze placed over the glass produced a reticulated pattern. But it required no such resisting substance as iron to shelter the glass. The patterns of the finest lace could be thus reproduced; the delicate filaments of the lace itself offering a sufficient protection. All these effects have been obtained with a simple model of the sand-blast devised by my assistant. A fraction of a minute suffices to etch upon glass a rich and beautiful lace pattern. Any yielding substance may be employed to protect the glass. By diffusing the shock of the particle such substances practically destroy the local erosive power. The hand can bear, without inconvenience, a sand-shower which would pulverize glass. Etchings executed on glass with suitable kinds of ink are accurately worked out by the sand-blast. In fact, within certain limits, the harder the surface the greater is the concentration of the shock, and the more effectual is the erosion. It is not necessary that the sand should be the harder substance of the two; corundum, for example, is much harder than quartz; still, quartz-sand can not only depolish, but actually blow a hole through a plate of corundum.—TYNDALL *Fragments of Science*, vol. i, ch. 7, p. 193. (A., 1897.)

3796. YOUTH AND AGE, GEOLOGICAL—Such, then, are the several stages through which a region of mountain-uplift must pass. First comes the stage of youth, when the surface configuration corresponds more or less closely with the underground structure. Next succeeds the stage of middle life, when such coincidence is all but obliterated, when the valleys of youth have been exalted and its mountains have been laid low. Last comes old age and final dissolution, when the whole region has been reduced to its base-level.—GEIKIE *Earth Sculpture*, ch. 5, p. 125. (G. P. P., 1898.)

3797. YOUTH THE PERIOD FOR FORMING PERSONAL HABITS—*Character Plastic before Twenty.*—If the period between twenty and thirty is the critical one in the formation of intellectual and professional habits, the period below twenty is more important still for the fixing of personal habits, properly so called, such as vocalization and pronunciation, gesture, motion, and address. Hardly ever is a language learned after twenty spoken without a foreign accent; hardly ever can a youth transferred to the society of his betters un-

learn the nasality and other vices of speech bred in him by the associations of his growing years. Hardly ever, indeed, no matter how much money there be in his pocket, can he even learn to dress like a gentleman born. The merchants offer their wares as eagerly to him as to the veriest "swell," but he simply cannot buy the right things. An invisible law, as strong as gravitation, keeps him within his orbit, arrayed this year as he was the last; and how his better-bred acquaintances contrive to get the things they wear will be for him a mystery till his dying day.—JAMES *Psychology*, vol. i, ch. 4, p. 121. (H. H. & Co., 1899.)

3798. ZERO-SIGN, VALUE OF—*Great Advance in Mathematics Due to a Sign for Nothing.*—[The] invention of a sign for nothing was practically one of the greatest moves ever made in science. It is the use of the zero which makes the difference between the old arithmetic and our easy ciphering. We give the credit of the invention to the Arabs by using the term Arabic numerals, while the Arabs call them Indian, and there is truth in both acknowledgments of the nations having been scholars in arithmetic one to the other. But this does not go to the root of the matter, and it is still unsettled whether ciphering was first devised in Asia, or may be traced further back in Europe to the arithmeticians of the school of Pythagoras. As to the main point, however, there is no doubt that modern arithmetic comes out of ancient counting on the columns of the abacus, improved by writing a dot or a round O to show the empty column, and by this means young children now work calculations which would have been serious labor to the arithmeticians of the ancient world.—TYLOR *Anthropology*, ch. 13, p. 315. (A., 1899.)

3799. ZONE, ABYSMAL—*The Lowest Depths of the Great Oceans—The Unknown Realm That Yet Baffles Science.*—The last well-marked zone is the abysmal, extending from the 500-fathom line to the greatest depths of the ocean, one of enormous superficial area, one that it is most difficult to investigate, and one about which we know but little. In the present state of our knowledge we cannot divide it into any well-marked subzones, nor even into geographical regions or subregions. It is not divided into sections by any important geographical barriers, and the general characters presented by its fauna are practically the same all the world over.—HICKSON *Fauna of the Deep Sea*, ch. 3, p. 50. (A., 1894.)

3800. ZONES, TEMPERATE, THE CHIEF ABODES OF LIFE—The astronomical contrast between the north and the south divides distinctly the different parts of the world into two separate groups. Almost the whole extent of the three northern continents belongs to the temperate zone, and it is only their most advanced peninsulas which are pushed forward—on the one side into the frigid, and on the other into the torrid zone. With regard to the three southern continents, they present their chief development between the tropics or in the south temperate zone. They receive the greatest amount of annual heat, and consequently become the theater of the most remarkable phenomena of planetary vitality. There the cross action of the winds and rains between the two hemispheres takes place, and hurricanes take their rise; there immense deserts extend over vast areas; there, too, vegetation manifests all its productive energy, and the terrestrial fauna attains its greatest force and its highest beauty.—RECLUS *The Earth*, pt. ii, ch. 10, p. 75. (H., 1871.)

INDEXES

INDEXES

TOPICS IN GENERAL

Numbers refer to selections, not to pages. References marked by a star (*) are the titles proper of the selections. Those not so marked are cross-references to matters of interest other than that indicated by the title proper of each selection. For a more extended system of cross-reference the reader is referred to the special index of "Topics with Cross-References" Attention is also called to the indexes of "Proper Names and Technical Terms," and of "Authors and Works Quoted"

P

TOPICS WITH CROSS-REFERENCES

Reference denotes not necessarily equivalence, but illustration or suggestion, sometimes contrast or even antithesis. Cross-references may often be followed out still more fully by looking up in the General Index also the topics referred to. Particular items, as the names of animals, instruments, etc., are to be sought in the General Index, and names of persons, places, etc., in the Index of Proper Names, or of Authors and Publishers.
